Immediately after ovulation the follicular tube of the ovariole, which has been greatly stretched to accommodate the mature egg, is an open expanded sac which retains the remains of the nurse cells and the follicular epithelium (the follicular relic) (Fig. 1). In the next few days the follicular tube begins to contract and the follicular relic is passed out of the ovariole. A greater part of the expanded follicular tube then becomes detached, possibly because the germarium is pushed towards the anterior end of the ovary by the growth of the other ovariole. After four days all that remains of the 'dilatation' is a small piece of tissue remaining on the posterior end of the follicular tube which resembles the 'funicle stumps' of parous *Anopheles gambiae* described by Lewis[5], and is evidence of ovulation (Fig. 2). As a complete dilatation as described for *M. uniformis*[3] is not formed, serial dilatations are never found in *Glossina morsitans*, and ovarioles which have ovulated twice or more cannot be distinguished from those which have only ovulated once. The sequence of ovulation, however, enables the number of eggs produced by a female to be determined up to the production of the fourth egg; after this it is impossible to tell how many eggs have been produced.

At 26° C., the fourth egg is ovulated (from the left ovary) 40 days after the emergence of the fly and therefore, at this temperature, flies may be aged up to at least the fortieth day by the number and position of the funicle stumps and the relative sizes of the four egg follicles. After the ovulation of the first egg (eighth or ninth day at 26° C.) eggs are ovulated about every 10 days, and the uterus contains either an egg or a developing larva. Each of the latter 10-day periods, therefore, may be subdivided by the stage of the offspring *in utero*. It is suggested that a combination of these observations could be used to determine the age of wild-caught tsetse flies.

Induction Phenomena in Photosynthesis of Isolated Spinach Chloroplasts

IN a number of papers concerning the induction phenomena during photosynthesis[1-5] I have determined the interrelationship between time and photosynthetic intensity as expressed by the photosynthesis time-curve. The sample plants used were mainly various species of moss[4]. In most cases the rate of photosynthesis was measured in terms of uptake of carbon dioxide ; but in a few cases the rate of oxygen given off was measured as well[3] : the determinations were made by means of the diaferometer method (the gas thermal conductivity method)[1].

Uptake of carbon dioxide sets in immediately the plant material is exposed to light, a peak appearing in the photosynthesis time-curve (Fig. 1, curve *A*). It appears to be reasonable to assume that this is due to the presence of a so-called carbon dioxide acceptor I, which is probably different from ribulose diphosphate, the latter coming into full action somewhat later and consequently being referred to as acceptor II[2,5]. It is further shown that at 15° C. the carbon dioxide taken up is normally transferred in the course of 5–6 min. to acceptor II, or, alternatively, that it enters the assimilation process proper in other ways[2,5]. If the illumination is suspended before this occurs a gush of carbon dioxide appears[2]. If the plants are heated at 40–50° C. for 3 min. prior to the measurements, the photosynthesis proper is found to have been inhibited completely. However, this is not true of the initial uptake of carbon dioxide by acceptor I. Probably a certain degree of inhibition exists in this case as well, but a very distinct peak is still found in the photosynthesis time-curve immediately following the onset of illumination. In these circumstances a gush of carbon dioxide appears when the light is switched off, its value corresponding to the amount of carbon dioxide fixed during the initial uptake. Similar reactions are found in cases where the plants are treated with cyanide, arsenate or iodoacetamide prior to the measurements, or if they are subjected to very high concentrations of carbon dioxide during the measurements[5,6].

In a number of papers, Arnon *et al.*[7-12] have demonstrated the practicability of effecting complete photosynthesis with isolated chloroplasts. They demonstrated the uptake of carbon dioxide in a suspension of chloroplasts to which had been added carbon-14, measuring the radioactivity of the dried chloroplasts[9]. In the present work the same isolation technique was used and by this means I succeeded in directly drawing the photosynthesis time-curve for a preparation of chloroplasts using the diaferometer method.

By means of the above isolation technique[9,10] the chloroplasts are obtained in the form of a suspension in 0·35 *M* sodium chloride. The uptake of carbon dioxide is reported to have been demonstrated by illuminating a mixture of this suspension with a *tris*-buffer solution (*p*H 7·4) to which have been added ascorbate and manganous chloride. Centrifugation of such a mixture in a centrifuge tube containing a piece of filter paper at the bottom results in the fixation of the chloroplasts on to the paper which can then be placed in the plant container of the diaferometer, where they are then exposed to an intensity of 6,500 lux at 15° C. in streaming atmospheric air to which has been added 3 vol. per cent of carbon dioxide. The results appear in Fig. 1. Curve *A* is the photosynthesis time-curve for an intact spinach leaf, and curve *B* is the corresponding curve for isolated spinach chloroplasts in contact with ascorbate and manganese chloride during the measurements.

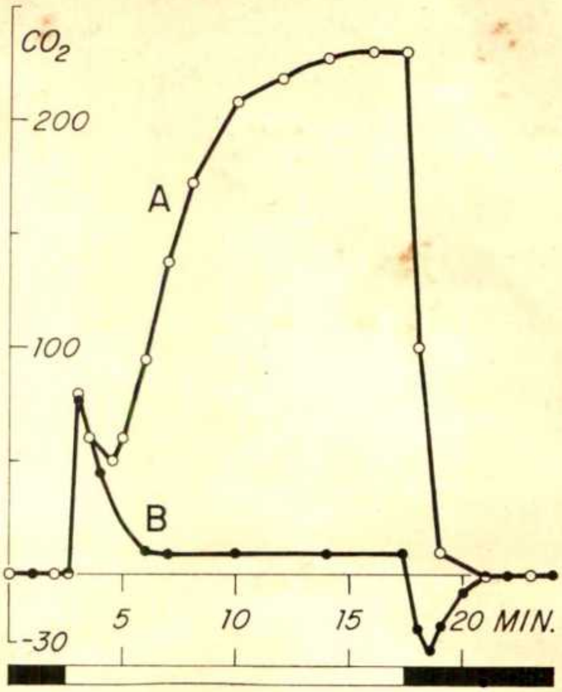

Fig. 1. Photosynthesis time-curves for an intact spinach leaf (*A*) and for isolated spinach chloroplasts (*B*) suspended in 0·35 *M* sodium chloride, added *tris*-buffer (*p*H 7·4), ascorbate and manganous chloride and fixed on to filter-paper. Ordinate, carbon dioxide uptake in arbitrary units ; abscissa, time (min.). Black and white areas indicate periods of dark and light on the plant material

This curve (*B*) is very reminiscent of the photosynthesis–time curves from intact leaves which had been exposed to heat, had been treated with cyanide, arsenate or iodoacetamide, or which during the measurements proper had been surrounded by air of an excessively high content of carbon dioxide (10–20 vol. per cent). There appear to be two possible explanations of this similarity. First, Arnon *et al.*[10] have shown that even a brief heating of the isolated chloroplasts at room temperature causes a considerable reduction of their ability to fix carbon dioxide on illumination. Hence it would appear to be conceivable that the reaction shown by intact leaves when heated for 3 min. at 40–50° C. in the chloroplast preparation experiments might occur already at lower temperatures. Secondly, although the chloroplasts were surrounded by a liquid containing ascorbate and manganous chloride during the measurements proper the experimental conditions must be considered to have been fairly unfavourable for the photosynthetic turnover[12]. Hence it appears to be permissible to a certain extent to compare them to similar ones which might be assumed to exist during certain toxic conditions when one or more steps in the mechanism of photosynthesis are paralysed.

In this connexion it is worth noting that if the chloroplasts only are suspended in a solution of buffer in 0·35 *M* sodium chloride without the addition of ascorbate and manganous chloride the photosynthesis–time curve shows only the initial peak during the light period and the gush of carbon dioxide during the terminating dark period, but no uptake of carbon dioxide after the development of the peak. One fact is conspicuous, namely, that although the photosynthesis proper in the chloroplast preparation is comparatively slight the initial peak in the time-curve is very distinct. As in the case of the whole leaves treated in any of the above ways, it may be established in this case also that the amount of carbon dioxide taken up immediately on the onset of illumination remains fixed throughout the duration of the light period, to be liberated afterwards in the form of a gush of carbon dioxide.

Hence the use of the diaferometer method offers the possibility of registering the initial as well as the subsequent uptake of carbon dioxide in isolated chloroplasts. The isotope technique used by Arnon, Allen and Whatley[10], on the other hand, allowed them to register only the amount of carbon dioxide which remains fixed even after the light has been switched off. The preliminary experiments here described appear to confirm the hypothesis mentioned concerning the function of acceptor I immediately upon the onset of illumination. They also show that this acceptor is found in the chloroplasts and that hence it must be considered to be part of the photosynthetic apparatus proper. Further photosynthesis experiments with isolated chloroplasts are in progress and will be published in detail elsewhere.

I wish to thank Prof. J. Moustgaard and Dr. A. Neimann-Sørensen of the Royal Veterinary and Agricultural College, who kindly placed at my disposal a refrigerated centrifuge. Thanks are also due to the Carlsberg Foundation for financial support of apparatus and technicians.

Hæmoglobin in the Root Nodules of *Casuarina cunninghamiana*

IN higher plants the respiratory pigment hæmoglobin has been detected only in root nodules of legumes[1,2]; it occurs there in all the species examined when nodulation is initiated by an effective nitrogen-fixing strain of the symbiont *Rhizobium*[2]. The presence of the pigment therefore appears to be possibly connected with the process of symbiotic nitrogen fixation.

Symbiotic nitrogen fixation is not, however, confined to the Leguminosae. Nine genera of Angiosperms, derived from six families, bear root nodules when an appropriate endophyte is present, and the capacity of these nodules to fix nitrogen at high rates is now well established. The quantitative work in this field has largely been carried out by Bond and his colleagues. Bond has recently reviewed the literature on the subject[4,5].

It is therefore not surprising that non-legume root nodules have been examined for the presence of hæmoglobin. Smith (quoted in ref. 6) was unable to detect the pigment in nodules of *Myrica*. Similar negative results were obtained by Egle and Munding[7] with *Alnus*, *Hippophaë* and *Myrica*, but they were able to show that the total hæmatin content of nodules of these genera, estimated as pyridine hæmochromogen, was 4–5 times greater than that of the cortex of non-nodulated roots. This work gave no indication of the manner in which the hæmatin occurs in the living cell. An opportunity to find whether it is present as a hæmoprotein, like all the known functional hæmatin compounds, was presented when Dr. G. Bond generously offered to supply nodulated material from *Alnus*, *Hippophaë*, *Myrica* and *Casuarina*. This had been obtained from plants grown in liquid culture in a medium devoid of combined nitrogen. A spectroscopic re-examination of the nodules seemed especially desirable in view of the high sensitivity of their fixation process to the presence of carbon monoxide[8].

The nodules of all four genera were found to possess a very active phenol oxidase system: the discoloration which occurred when nodules were crushed in water or dilute phosphate buffers hindered, and sometimes precluded, spectroscopic examination. It was found that this discoloration was decreased by using 0·2 *M* *tris* (2-amino-2-hydroxymethylpropane-1:3-diol) buffer, *p*H 7·4, containing 0·02 *M* sodium ethylenediamine tetraacetate. For the estimation of total hæmatin the weighed nodules were ground in this medium with the addition of sufficient sodium dithionite to exclude dissolved oxygen. The ground material was transferred to a Thunberg tube, pyridine was added to 30 per cent (v/v) and the tube evacuated. The contents of the tubes showed the spectrum of pyridine protohæmochromogen when viewed with a Zeiss pupillary spectroscope against a strong light. The concentration of hæmochromogen was estimated by comparing the spectrum of the vacuum tube contents with that of a pyridine hæmochromogen standard derived from bovine hæmin in the spectrocolorimeter described by Hill[9]. These measurements (Table 1) confirm the results of Egle and Munding[7] and extend them to the genus *Casuarina* in which the level of hæmatin was always higher than in the other genera and was, in fact, comparable with that in leguminous root nodules[3].

Spectroscopic examination of preparations of *Casuarina* nodules ground in the *tris* medium with dithionite showed a diffuse absorption band with a maximum at 562 mμ. This band is similar to that of deoxygenated hæmoglobin and is unlike the sharp α-band of a cytochrome or hæmochromogen. An attempt was made to observe the oxygenated compound by omitting dithionite from the grinding

Table 1. TOTAL HÆMATIN CONTENT OF NODULE AND ROOT TISSUES

	μmoles hæmatin/gm. fresh weight ($\times 10^2$)	
	Nodules	Root cortex
Alnus glutinosa	4·85	0·6
Myrica gale	5·5	0·5
Hippophaë rhamnoides	4·2	0·5
Casuarina cunninghamiana	12·0	0·7
Pisum sativum	10·8	—

medium. Rapid spectroscopic observation immediately after grinding then showed two absorption bands, with maxima at 580 mμ and 544 mμ, resembling those of oxyhæmoglobin. This spectrum was ephemeral and the bands rapidly faded as the tissue debris became discoloured by the phenol oxidase activity; the change might have been due to oxidation of hæmoglobin iron by quinones produced by the phenol oxidase[2]. An indication that oxidation to a compound similar to methæmoglobin had occurred was obtained by adding fluoride to the preparation, when an absorption band, resembling that of fluoride methæmoglobin, appeared at 610 mμ.

Although these observations suggested that *Casuarina* nodules contain a pigment with the spectroscopic properties of a hæmoglobin, the rapid disappearance of the oxyhæmoglobin type of spectrum in the macerated preparations made it difficult to establish that the pigment can undergo alternate deoxygenation and oxygenation without change in valency of the hæm iron. This capacity for reversible combination with molecular oxygen is the essential property of hæmoglobin and is the basis of its function as a respiratory pigment. Unequivocal evidence on this point was, however, obtained by spectroscopic examination of the intact nodules. For this purpose a small cluster of nodules was mounted in a drop of the *tris* medium in a cell on a microscope slide. When the cluster was illuminated, on the microscope stage, by the condensed light of a 500-watt projection lamp, sufficient light was transmitted by the less-opaque portions of the nodule cluster for spectroscopic examination to be made, using a 16-mm. objective with the Zeiss pupillary spectroscope as ocular.

With the untreated nodules a spectrum with two absorption bands, at 580 mμ and 542 mμ, could easily be observed. When a small amount of sodium dithionite was added to the fluid surrounding the nodules the two bands were slowly replaced by a single diffuse band at 562 mμ. What is more significant, however, is that when the dithionite solution was then replaced by fresh *tris* medium the two-banded spectrum reappeared. This sequence of events also occurred in the absence of a reducing agent if the nodules were allowed to respire the dissolved oxygen in the fluid surrounding them and air was then readmitted. Confirmation that the hæm iron of the pigment is in the ferrous state *in vivo* was obtained by treating the nodules with carbon monoxide, when two diffuse absorption bands at 572 mμ and 542 mμ replaced the characteristic spectra of either the oxygenated or deoxygenated derivative. The hæm pigment of *Casuarina* root nodules appears, therefore, to possess the essential properties of hæmoglobin.

An estimate of the proportion of the total hæmatin occurring in the form of hæmoglobin was obtained by grinding nodules in the *tris* medium with added dithionite, treating the preparation with carbon monoxide in a Thunberg tube, and comparing the spectrum of the tube contents with that of a standard solution of carboxymyoglobin prepared from sperm whale muscle. In nodules containing 0·11 μmole total hæmatin/gm. fresh weight, carboxyhæmoglobin accounted for 0·083 μmole.

The hæmoglobin of leguminous root nodules is readily extracted by aqueous solvents[2]. That of *Casuarina*, on the other hand, remains firmly bound to the cell debris under all the extraction conditions so far examined. Spectroscopic evidence was obtained that the nodules of *Alnus* and *Myrica* also contain a bound form of hæmoglobin similar to that in *Casuarina*. It is hoped to confirm this when material becomes available in the next vegetative season.

The above observations represent the second finding of hæmoglobin in higher plants; they emphasize the connexion that appears to exist between symbiotic nitrogen fixation and the presence of the respiratory pigment, but go no further towards an explanation of the nature of this connexion.

Occurrence of a Non-Fibrillar Elastin in the Earthworm

THE cuticle of the earthworm's gizzard is generally thought to be chitinous; but there was no experimental evidence for this view, until the observation by Rudall[1], who obtained an X-ray diffraction diagram similar to that found in *Aphrodite* bristles previously described by Lotmar and Picken[2] as a modified chitin (β-chitin). Although after purification he obtained a different diagram, he nevertheless concluded that the gizzard membrane was probably chitinous in nature. This identification is much less convincing in view of the fact that the structural proteins are always found together with a certain amount of polysaccharides[3].

As a part of a more comprehensive study of the earthworm gut[4], I have tried to ascertain the chemical nature of the gizzard cuticle by means of histochemical, physical and chemical methods.

(1) *Histochemical results:*

(*a*) *Polysaccharides.* No specific polysaccharide test gave any truly positive results. The periodic acid–Schiff reaction gives the cuticle a rose tinge, and alcian blue stains it only after oxidation by the acid permanganate reagent.

(*b*) *Elastins and collagens.* Whereas the ectodermal cuticle and the epithelial basement membrane show the same affinities as the collagens, the gizzard cuticle responds positively to tests for elastin. No other structure in the earthworm shows the same combination of tinctorial properties (Table 1).

(2) *Physical and chemical results*: The properties of the gizzard cuticle isolated by dissection are the same as those of vertebrate elastin, except for birefringence and autofluorescence (Table 2). These last properties are probably connected with the

Table 1

Test	Elastin (vertebrate)	Collagen (vertebrate)	Cuticle (gizzard)
Tetrazotized benzidin	brown	purple-brown	brown
The same, after moderate benzoylation	yellow	purple	yellow
Gomori (following Gabe)	violet	blue	violet
Van Gieson	yellow or rose	red	rose
Weigert's resorcin	violet	rosish	violet
Orcein	red	brownish	red

Table 2

Test	Vertebrate elastin	Vertebrate collagen	Arthropod chitin	Earthworm skin cuticle	Gizzard cuticle
Birefringence	weak	positive		positive	negative
Autofluorescence	positive	negative		negative	negative
'Solubility' in 5 per cent pot. hydrox. at 100° C. in 24 hr.	insoluble	soluble	insoluble	soluble	insoluble
'Solubility' in 6 *N* hydrochloric acid at 20° C.	insoluble	soluble	soluble	soluble	insoluble
'Solubility' in 2 per cent acetic acid	insoluble	soluble	insoluble	soluble	insoluble
Pepsin	very resistant	soon attacked	fully resistant	soon attacked	not attacked after 6 hr.
Trypsin	very resistant	attacked after mechanical mincing	fully resistant	soon attacked	not attacked after 6 hr.

particular physical structure of these cuticular membranes. In fact, they do not show any fibrillar structure, whether examined by ordinary or phase-contrast microscopy.

(3) *Chromatographic results:* 12 gizzard cuticles from the earthworm *Lumbricus rubellus* were purified and hydrolysed following a modification of the technique described by Neumann and Logan[5]. The hydrolysate was run on a circular chromatogram with the mixture butanol/acetic acid/water (4 : 1 : 1), and visualized with ninhydrin. Although no quantitative analysis was made, proline, valine and glycine seem to be particularly abundant. Hydroxyproline, typical of collagens and elastin, was detected on a separate chromatogram by the 'dipping' method of Jepson and Smith[6].

I conclude, therefore, that histochemical, physical and chemical evidence agrees with the view that the cuticle of the earthworm gizzard is an elastin in nature. This particular one is a 'non-fibrillar' elastin, analogous to the secreted collagens previously described in some invertebrates, notably in the ectodermal cuticle of *Lumbricus*[7]. I suggest calling it a 'secreted elastin'.

RADIOBIOLOGY

Fall-out Radioactivity in Southern Sweden

A high enrichment of radioactive fall-out products was recently reported in plant ash from southern Sweden[1]. The highest values were recorded in plants growing near the coast or upon pronounced hills, while plants growing in lowland regions at greater distances from the sea gave the lowest values. In all the samples examined the natural radioactivity was quite subordinate to the radioactivity caused by fall-out.

With the view of a more detailed investigation of the distribution of fall-out radioactivity in the soil and in the vegetation, the ash of different parts of a spruce taken from an area of comparatively high fall-out radioactivity was examined by means of a Geiger counter (Table 1).

Table 1. Relative Radioactivity Values (Background, 1·0) of Ash of Different Parts of 6 m. High Spruce from Romeleasen (120 m. above Sea-level), Southern Sweden, collected and analysed in October 1959

	Age	Ash (per cent)	Relative radioactivity
Needles	1 year	3·6	1·2
Needles	2 years	3·6	1·8
Needles	3 years	4·7	1·8
Live twigs	1 year	3·2	1·6
Live twigs	2 years	2·0	3·6
Live twigs	3 years	2·3	3·8
Dead twigs		1·8	3·3
Trunk, bark		2·8	1·8
Trunk, wood	1 year	0·7	1·0
Trunk, wood, central		0·3	1·0
Root, bark		3·1	1·0
Root, central		0·3	1·0
F-layer soil profile		12·8	1·3
Mineral soil		—	1·0

It appears from these figures that there is a marked enrichment of radioactive substances in both the twigs and the needles. On the other hand, no increase of radioactivity was found in the woody parts of the trunk or of the root or in the bark of the root.

Some γ-spectrometric analyses of parts of the spruce (ashed samples) have been carried out through the courtesy of Dr. K. Edvarson at the Swedish Research Institute for National Defence. These analyses revealed that the percentage of cæsium-144 and niobium–zirconium-95 was more than ten times higher in 1·5-year-old twigs and needles than in those of age 0·5 year. The radioactivity of the central woody part of the trunk was far below that of the exposed parts of the tree and was dominated by potassium-40. The γ-spectrometric analyses demonstrate the decrease in fall-out radioactivity during the last season and also the almost complete absence of fall-out products in the woody parts of the tree.

Additional Geiger-counter measurements have shown that dead parts of trees and plants (dry twigs, etc.) often have as high a radioactivity as live parts, even if they have been dead for several years. The decrease in radioactivity with time is the same for these dead parts as for the live parts of the plants, and it is evident that this radioactivity is due to the presence of relatively short-lived radioactive isotopes. This indicates, when considered together with the observations reported above, that the fall-out radioactivity, or at least the dominating part of it, has been mainly taken up by exposed parts of the plants directly from the air and only to a very small extent from the soil through the root-system of the plant. This observation is in line with what is mentioned by Gorham[2], namely, that certain small plants which have a low ash content and a corresponding large surface show a considerable enrichment in fall-out products.

It is thus evident that the main part of the fall-out radioactivity is now concentrated in the vegetation and in the uppermost layer of the soil where decaying plant parts dominate. This is especially the case with the more short-lived fission products, whereas the long-lived ones will possibly reach a higher enrichment through a more complete soil–plant–soil cycle.

Autoradiographic exposures of plants, plant parts, and of ashed-plant samples demonstrate the same distribution of radioactivity as mentioned above. There is a marked blackening of the photographic film by needles, leaves, twigs, and bark, contrary to the wood which does not affect the photographic film. The autoradiographs show, furthermore, that there are two kinds of radioactive influence. The first and general type causes a slight blackening of the photographic film. The second type is found when examining more recent samples, and it causes the development of small, intensely black dots on the film. These autoradiographic analyses signify that there are at present two sizes of fall-out particles, one very fine-grained and the other more coarse-grained, the latter representing a highly concentrated radioactivity.

Calcium Binding in Homogenates of Ehrlich Ascites Tumour Cells

WE have recently been attempting to determine the amount of bound (non-diffusible) calcium in the cells of the mouse Ehrlich ascites tumour. Results not yet published indicate that more than 50 per cent of calcium-45 incorporated *in vivo* by the cells is removed by briefly washing them three times in calcium-free balanced salt solution.

In order to investigate further the bound calcium, we disrupted the cells and examined the homogenate. This was done by suspending the cells, which had been labelled *in vivo* with calcium-45, in ice-cooled buffered isotonic salt solution, and then disrupting them by exposure to ultrasonic vibrations of about 20 kc./s. for 2 min. with the *M.S.E.*-Mullard apparatus. The resulting homogenate was subjected to a conventional dialysis procedure at 4–6° C. against a calcium-free solution. Initially calcium-45 was lost from the homogenate very slowly, as indicated by the slight increase in the radioactivity of the solution against which it was dialysed (Fig. 1). This phase lasted about 90 min., after which calcium was lost rapidly, as shown by the steep portion of the curve of radioactivity of the dialysing solution. A similar curve is obtained even if the isotope is added to homogenized cells *in vitro*. A totally different curve is obtained on dialysing ascitic fluid, in which there is a bound, but exchangeable, calcium fraction. In this case, the increase in radioactivity of the solution against which the labelled fluid is dialysed shows a steep rise from zero time, and flattens only when equilibrium is nearly attained (Fig. 1).

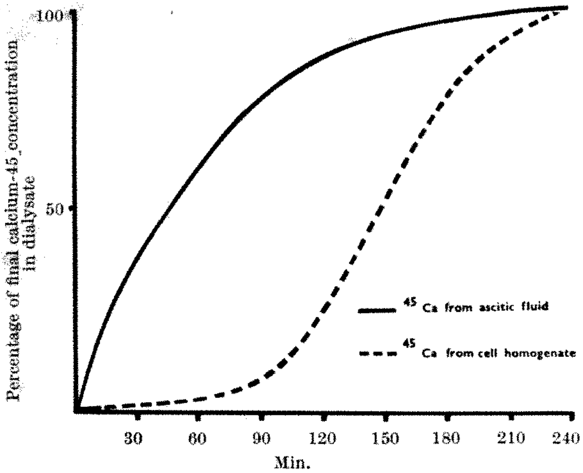

Fig. 1

Preliminary experiments also indicate that the total amount of calcium-45 removed from the labelled homogenate by dialysis, even after 4 hr., is considerably less than that extracted by quickly washing the cells in calcium-free solution, and probably amounts to less than 20 per cent of that initially present.

This increase of binding of calcium-45, and hence of total calcium, is corroborated by the very slow migration of the tag towards the cathode from the point of application of the labelled homogenate, when this is subjected to paper electrophoresis.

It appears that, as a result of the disintegration, a number of new calcium-binding sites have been made available. The increase in base-binding capacity may be accounted for, *inter alia*, by (*a*) molecular damage produced by subjection to the ultrasonic vibrations, or (*b*) by existing groups, previously inaccessible to the base, being made available by disruption of the cells.

Clearly, a study of the normal distribution of calcium in different cell fractions would be falsified by the increase in the proportion of bound calcium produced by ultrasonic disruption. We are therefore investigating further the nature of the binding in whole cells and in homogenates.

VIROLOGY

Purification and Properties of Cauliflower Mosaic Virus

STRAINS of cauliflower mosaic virus occur very commonly throughout North America and Europe. Previous attempts to determine the morphology of the virus[1], and to obtain an antiserum to it[2], were unsuccessful. Following the recent purification of cucumber mosaic virus[3], an attempt was made to purify cauliflower mosaic virus using similar procedures.

The cabbage virus *B* strain of the virus, described by Walker *et al.*[4], was mechanically inoculated to leaves of young tendergreen mustard plants (*Brassica perviridis* Bailey). Two to three weeks after inoculation, systemically infected leaves were harvested and homogenized in a Waring blendor in 0·5 *M* potassium phosphate buffer (*p*H 7·5) containing 0·1 per cent thioglycollic acid, at the rate of 12 ml. of buffer for each 10 gm. of leaf tissue. The homogenate was strained through cheese-cloth and *n*-butanol added dropwise with constant stirring to give a final butanol concentration of 8 per cent. The mixture then was stirred for 1 hr., after which it was centrifuged for 15 min. at 5,000 r.p.m. in a model *SP* Servall centrifuge. The clear supernatant was filtered through glass-wool and centrifuged for 2 hr. at 30,000 r.p.m. in a No. 30 rotor of a Spinco model *L* ultracentrifuge. Following ultracentrifugation, the supernatant was discarded and the pellets resuspended in 2–3 ml. of distilled water, and placed on a mechanical shaker for 8–10 hr. The pellet suspension was then centrifuged for 1 min. at 25,000 r.p.m., and the pellet discarded. All operations were carried out at 2–4° C.

Electron microscopic examination of grids sprayed with the final supernatant revealed particles of two sizes, 18 mμ and 50 mμ, while healthy leaf extracts processed in the same manner contained only the smaller particles.

Further purification was achieved by density gradient centrifugation. 1-ml. aliquots of the partially purified virus were layered on to tubes containing 30 ml. of a 5–40 per cent sucrose gradient and centrifuged in a Spinco *SW*-25 rotor for 2 hr. at 25,000 r.p.m. Examination of the gradient tubes under a beam of light revealed an opalescent band midway down the tubes. No such band was present in healthy preparations treated in a similar manner. The material within the bands was carefully withdrawn with a hypodermic needle through the side of the tubes, and dialysed for 12 hr. against distilled water. These virus preparations were assayed for infectivity on tendergreen mustard and typical symptoms of the disease appeared 10–20 days following inoculation, the time varying with the dilution of the virus preparation. These preparations were infectious up to dilutions of 10^{-5}. Aliquots of these preparations were sprayed on collodion-coated electron microscope grids, freeze-dried, and shadowed with uranium. When examined with the electron microscope, the grids sprayed with the virus showed numerous uniform spheres with an average diameter of 50 mμ. None of the smaller particles observed in partially purified preparations was present (Fig. 1).

The purified virus, suspended in 0·02 *M* sodium phosphate buffer (*p*H 6·0), was found to have a sedimentation coefficient of approximately 222 *S* at 20° C. when centrifuged in a Spinco model *E* ultracentrifuge at 17,980 r.p.m.

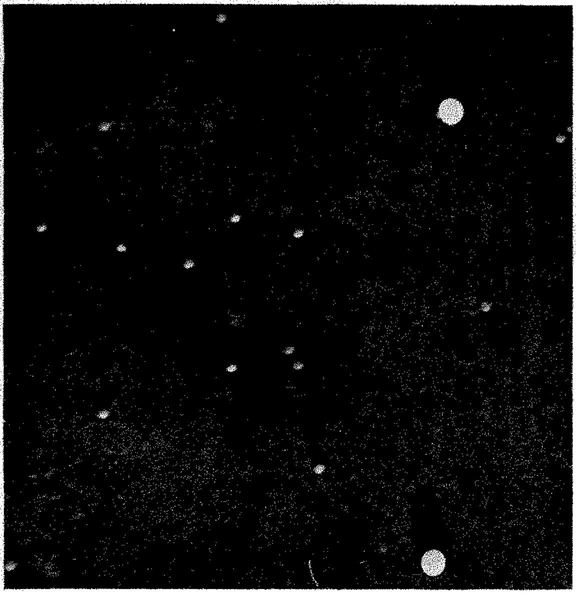

Fig. 1. Electron micrograph of purified cauliflower mosaic virus (× 24,490). The large white spheres are polystyrene latex particles, 122·5 mμ in diameter

Purified preparations of the virus were injected into rabbits intramuscularly, using Freund's adjuvant, and intravenously, at 7–10 day intervals for a total of 6 injections. The rabbits were bled 10 days after the last injection. Serum used in ring tests with the virus gave positive reactions at serum dilutions up to 1/512. The virus did not react with normal serum, or with antisera of turnip yellow mosaic or turnip mosaic viruses. Purified preparations of turnip yellow mosaic and turnip mosaic viruses gave no reaction when tested against cauliflower mosaic virus antiserum.

We wish to express our thanks to Dr. P. J. Kaesberg, Dr. J. J. Kelley and Mrs. Selma Sachs of the Department of Biochemistry, University of Wisconsin, for their assistance with the electron microscope and sedimentation coefficient studies.

Decarboxylation of Glutamic Acid in Tobacco Leaves inoculated with Tobacco Mosaic Virus

THE process of decarboxylation of glutamic acid has been a subject of interest since the discovery in many plants of γ-amino-butyric acid in large quantities[1-3].

Since proteins do not contain these acids, the role of the process of decarboxylation is not quite clear. But the appearance of the process at all the stages of development suggests that its role in plant metabolism may be more general[4,5].

I have examined the intensity of decarboxylation in *Nicotiana tabacum* var. White Burley, inoculated with tobacco mosaic virus. Typical results are given in Table 1. The results show that at certain stages of the mosaic disease the activity of the process increases.

Table 1. ACTIVITY OF GLUTAMIC ACID DECARBOXYLASE IN TOBACCO LEAVES HOMOGENATES

Days since inoculation	Carbon dioxide (μl.) in 30 min. at 30° C.		Activation (per cent)	Atmosphere
	Sound	Infected with tobacco mosaic virus		
6–8	51·8	57·1	110	Air
	56·4	89·3	158	
6–8	47·8	67·0	141	Nitrogen
	51·9	73·0	140	
11–14	47·8	100·6	210	Air
	51·9	116·0	220	
11–14	46·8	67·7	144	Nitrogen
	35·5	76·1	214	

5 gm. of the tissue with 15 ml. 1/15 *M* phosphate buffer *p*H 5·6 was ground until a homogeneous suspension was obtained. 0·2 ml. homogenate and 1 ml. glutamic acid in concentration 0·02 *M* were poured into a Warburg apparatus.

The greatest intensity of decarboxylation in leaf homogenates was found in young leaves when the mosaic began to appear (11–14 days after infection)—the activation reaching 200 per cent. The second maximum of the decarboxylation of glutamic acid was observed several days after inoculation (140 per cent).

To explain the increase in decarboxylation of glutamic acid found in tobacco leaves inoculated with tobacco mosaic virus, I suggest the phenomenon is connected with destructive metabolism because maximum intensity of the process occurs when the disorder symptoms begin to appear, or it may be involved in the synthesis of virus proteins.

The second view is backed by indirect results of other workers. Analysing free amino-acids in the coconut endosperm, Baptist found that the γ-amino-butyric acid appears in the period of intensive protein synthesis[6]. Pekka and Virtanen have shown that metabolism of γ-amino-butyric acid is strictly connected with glutamine, which is assumed to play an important part in protein synthesis[7]. The examination of the process and its role in virus synthesis is being continued.

BACTERIOLOGY

Streptomycin-induced Lysis of Penicillin-treated *Staphylococci*

WHEN growing cultures of *Escherichia coli* are exposed to bactericidal concentrations of penicillin, lysis of the cells occurs after 20–30 min.[1]. This lysis appears to be caused by the inhibition by penicillin of synthesis of cell wall mucopeptide with continuing synthesis of other cell constituents, resulting in 'bursting' of the cells[2]. Other cases of lysis of bacteria due to such a reduced differential rate of synthesis of cell wall mucopeptide are known, and have recently been reviewed[3,4].

When penicillin, at a minimally bactericidal concentration (0·06 μgm./ml.), is added to growing cultures of *Staphylococcus aureus* (strain Duncan), rapid lysis of the cells does not occur although the synthesis of cell wall mucopeptide ceases after about 15 min.[5]. Only a very slow fall, continuing for more than 24 hr., is observed in the optical density of such cultures, and it is not clear why the rate of lysis in these *Staphylococci* is so low compared, for example, with penicillin-treated *E. coli*[1,2] or lysine-deficient *Streptococcus faecalis*[6]. One possibility which suggests itself is that, due to the reduced activity of amino-acid-accumulating systems in *Staphylococci* which follows contact with penicillin[5,7], the rates at which cell constituents other than the cell wall can be synthesized are reduced, so that 'bursting' occurs more slowly.

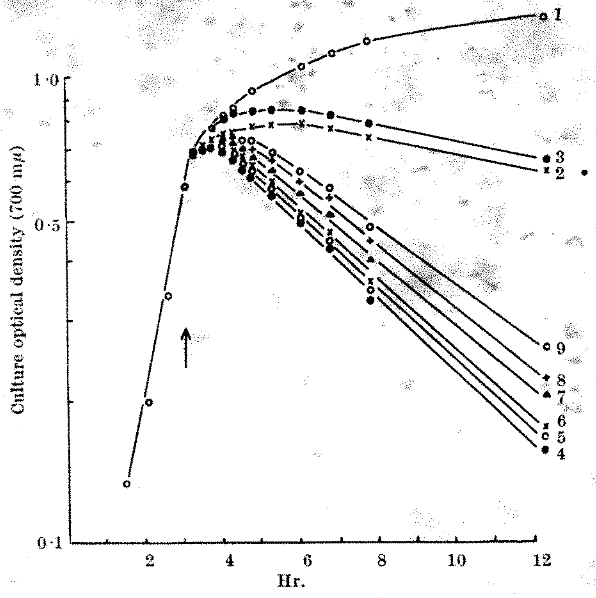

Fig. 1. To identical cultures of *Staphylococcus aureus* (strain Duncan) growing in *PG* medium (ref. 9) at 37° in shake flasks, additions were made (at the time indicated by the arrow) of streptomycin (10 μgm./ml.) (*S*) and/or penicillin (0·06 μgm./ml.) (*P*) as follows. *S* (curve 1); *P* (curve 2); *S* followed after 30 min. by *P* (curve 3); *P* and *S* together (curve 4); *P* followed by *S* either after 10 min. (curve 5), after 20 min. (curve 6), after 30 min. (curve 7), after 40 min. (curve 8), or after 50 min. (curve 9)

During investigations of the effects of streptomycin on *S. aureus*, I have recently observed, however, that addition of streptomycin together with penicillin (each at minimally bactericidal concentrations) to exponentially growing cultures brings about rapid lysis (Fig. 1). This lysis begins at *c.* 30 min. after addition of streptomycin, even when this is delayed up to 50 min. after addition of penicillin. Although the rate of lysis is independent of the concentration of streptomycin when this is greater than 10 μgm./ml., lysis commences earlier at higher streptomycin concentrations. Lysis is induced only by those derivatives of streptomycin which possess antibacterial activity (dihydrostreptomycin, mannosido-

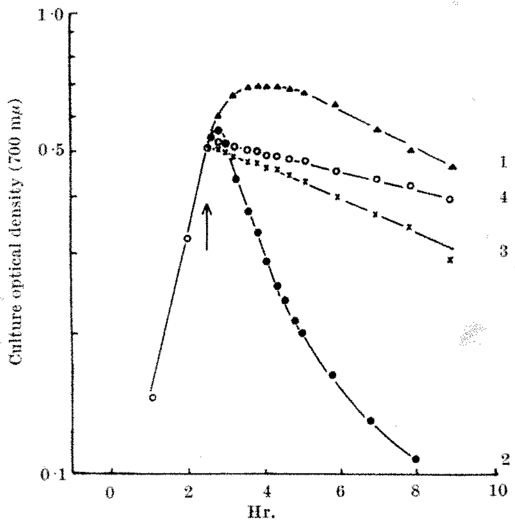

Fig. 2. To cultures growing as in Fig. 1 were added (at the time indicated by the arrow): penicillin (0·06 μgm./ml.) (curve 1); penicillin (0·06 μgm./ml.) + streptomycin (10 μgm./ml.) alone (curve 2), or together with chloramphenicol (50 μgm./ml.) (curve 3), or together with 8-azaguanine (500 μgm./ml.) (curve 4)

streptomycin) and not by streptidine or streptomycinic acid; it does not occur under anaerobic conditions, when the bactericidal effect of streptomycin on this organism is also much reduced. Essentially similar results have also been obtained using strain *H* of *S. aureus*.

When the growth-rate of a culture, previous to addition of penicillin and streptomycin, is reduced by decreasing the concentration of peptone in the growth medium, the rate of subsequent lysis is reduced proportionally. Lysis can be almost completely prevented by addition, simultaneously with penicillin and streptomycin, of chloramphenicol (50 μgm./ml.) or 8-azaguanine (500 μgm./ml.) (Fig. 2). However, chloramphenicol can prevent the bactericidal effect of streptomycin on *S. aureus* (Hancock, R., unpublished results), so that this finding does not necessarily indicate that lysis under these conditions is a result of 'unbalanced synthesis' of other cell constituents relative to cell wall. The possibility that lysis may be caused by cell wall-degrading enzymes of the type found in *Staphylococci* by Mitchell and Moyle[8] seems unlikely since we have not been able to detect any activity of these enzymes in cells after growth for 30 min. in the presence of streptomycin.

I am grateful to Mr. F. McManus for valuable technical assistance, and to the Distillers Co. and to Merck and Co., Inc., for gifts of streptomycinic acid and streptidine, respectively.

Influence of Light on Bacterial Flora of Roots

ALTHOUGH considerable work has been done on the influence of various factors such as type, moisture content, reaction and treatment of the soil and kind and age of plant on the microflora of the rhizosphere[1], very little has appeared concerning the response of the normal rhizosphere micropopulation to the changes in plants growing under different light intensities. The studies that have been made deal primarily with specific phenomena such as symbiotic nitrogen fixation[2], mycorrhizal development[3] and susceptibility of roots to infection[4]. However, Rovira[5] has recently reported that "the numbers of bacteria in the rhizosphere of tomato were reduced by 60 per cent when plants were shaded to 40 per cent of full sunlight"; the conditions under which the plants were grown were not given. We have recently completed experiments on the influence of light on the microbial population of wheat roots. These were selected for analysis rather than the soil adhering to them because it was considered that the organisms in intimate contact with the roots would reflect more accurately the changes produced in the plant by differences in illumination than would the organisms in the rhizosphere soil, where a dilution of the effect would probably occur. Certain of our findings relating to the bacterial flora are presented here. Full details of these experiments will be published elsewhere.

Wheat was planted in field soil in large rectangular tanks in the greenhouse. The plants were grown under 'normal light' for two weeks after which a cheesecloth cage was placed over half of them, thus reducing the light from approximately 1,000 to about 300 foot-candles. The temperature at the soil-level showed little significant variation between the illuminated and 'reduced light' sets. Moisture was maintained at about 70 per cent of the soil-moisture holding capacity by regular sprinkling. Composite root-samples were obtained three weeks after shading by removing plants from four locations in each treatment. The roots were thoroughly washed for 5 min. by shaking in sterile water and then washed aseptically in three changes of water prior to homogenization in a sterile Waring blendor. The homogenate was analysed microbiologically using methods described in previous publications from this laboratory[6,7]. The results of a typical experiment are summarized in Table 1.

Table 1. INFLUENCE OF ILLUMINATION ON THE BACTERIAL FLORA OF WHEAT ROOTS*

Bacteria	Illumination (ft.-candles)	
	1,000	300
Plate count	7.9	3.9
Methylene blue reducers	50.0	6.0
Glucose fermenters		
Acid producers	3.0	0.38
Gas producers	0.8	0.06
Ammonifiers†	16.0	0.2
Incidence of amino-acid requiring bacteria (per cent)	65	30

* Numbers in thousand million per gm. oven dry roots; methylene blue reducers, glucose fermenters and ammonifiers were estimated by the ultimate dilution procedure (ref. 7).

† These results were derived from a later experiment.

A distinct reduction in bacterial count and in numbers of methylene blue-reducing organisms (as an index of the overall activity on the root surface) as well as of glucose-fermenting bacteria occurred on the roots of plants grown under low light intensity. Further tests revealed that numbers of ammonifying bacteria were also reduced on these roots. Nutritional studies on isolates from the plates used for counting showed a marked reduction in the percentage incidence of bacteria requiring amino-acids for maximum growth from about 65 per cent to 30 per cent. Taxonomic studies with these isolates are in progress. The results suggest that there is both a quantitative and a qualitative change in the substances excreted by these roots which normally stimulate the microflora at or near the root surface and produce the 'rhizosphere effect'[1]. Of course the reduced amounts of these materials, particularly of amino-acids, at the root surface may be due partly to the decrease in the total bacterial population on the root, resulting in a concomitant reduction in the elaboration of various substances, including amino-acids[8]. Rovira[5] has reported a reduction in excretion of certain amino-acids by the roots of plants grown aseptically under reduced light, but mentioned also that the presence of micro-organisms influenced the concentration of amino-acids in the solution surrounding tomato roots. However, the numbers of bacteria which do not require amino-acids and which may liberate them appear to be very similar on the roots of both sets of plants used in the present experiments (35 per cent of $7\cdot9 = 2\cdot76$ thousand million in the 'high light' series as compared with 70 per cent of $3\cdot9 = 2\cdot76$ thousand million in the 'low light' set). The plant, therefore, may be the major source of amino-acids for these organisms requiring them.

The significance of these observations with regard to plant nutrition, growth or susceptibility to disease is difficult to assess, especially since the role of the normal rhizosphere soil and root-surface microflora is still imperfectly understood. Eaton and Rigler[9] have reported decreased susceptibility of cotton plants to *Phymatotrichum omnivorum* as a result of defoliation or mutilation of the plants, which increased the carbohydrate content of the roots. This effect was associated also with a reduction in total bacterial numbers and an increase in numbers of fluorescent bacteria. Harley and Waid[10] observed an increase in the incidence of semi-pathogenic fungi on roots of beech seedlings grown in the shade. Whether these results are due to a concomitant reduction of the bacterial and possibly of the actinomycete population at the root surface, to an alteration of the types of organisms, as suggested above, or to changes in the plant and in the root which render them less able to withstand parasitic attack is not clear at present although the increased susceptibility of plants growing under reduced illumination to diseases produced by viruses, fungi and nematodes has been reasonably well established[11,12].

Iron Bacteria in Mine-waters

As van Beneden[1] has shown, iron bacteria may be obtained from fresh-water by reducing the iron in this water by percolation through a layer of soil. In the thin layer where the effluent oxidizes (presumably ferrous carbonate or bicarbonate to hydrated ferric oxide) the bacteria develop.

Baas Becking, Wood and Kaplan[2], using this method, obtained iron bacteria from sea-water. With the help of Mr. A. D. Haldane, senior chemist of the Bureau of Mineral Resources, a more efficient apparatus was constructed. Iron bacteria were grown on slides on which a reduced fresh-water effluent was dripping. Tap-water can be made free of oxygen by passing it through a column of steel-wool, previously washed in carbon tetrachloride. The effluent contains a slate-blue compound, possibly ferrous hydroxide, which oxidizes slowly to hydrated ferric oxide. Ferrous carbonate (and possibly the soluble bicarbonate) are formed and oxidized in culture flasks containing the infection material and a small amount of magnesium-ammonium phosphate.

As infection material, chalybeate waters from various localities in New South Wales were used (Matraville, Mittagong, Warrah, Palm Cave, Bungendore). Both a sheathed rod and a species of *Sphaerotilus* made their appearance. The method, however, is cumbersome and unsuitable for pure culture work.

The oxidation of pyrite proceeds in sterile suspensions, yielding ferrous sulphate and acid. In sterile suspensions, the oxidation of ferrous to ferric sulphate is very slow, only a few per cent being converted in four months at room temperature.

Iron bacteria isolated from chalybeate waters are capable of catalysing the oxidation of ferrous to ferric sulphate, the reaction running to completion in a few weeks at room temperature. It is possible to obtain pure cultures of these forms on 1 per cent ferrous sulphate agar containing 200 mgm./l. magnesium-ammonium phosphate. Pure cultures could also be obtained on powdered pyrite agar.

One of the final oxidation productions of pyrite is a mixture of ferric sulphates and oxysulphates, called 'yellowboy' by the miners. This ore, collected from various levels, Lake George Mine, Captains Flat, New South Wales, proved to contain *Sphaerotilus* and also *Gallionella*. The former could be isolated on 1 per cent ferrous-sulphate agar and on pyrite agar. Mine-water from the same mine contained *Sphaerotilus*.

A constant companion of both *Sphaerotilus* and the bacillary form is a small *Torulopsis*-like yeast, present in both mine-water and fresh-water, which also appeared from hydrated iron oxide collected near a hot spring at Talasea, New Britain.

Gallionella could not be isolated on sulphate media, but there are, apparently, iron organisms capable of developing on the ferrous (bi)carbonate as well as on the ferrous sulphate system.

In the latter system they give rise to electrode potentials of $+860$ mV.

The first stage in the oxidation of pyrite, where ferrous sulphate and acid are formed (pH $1\cdot5$–$3\cdot0$), is a purely chemical phase, as the oxidation proceeds with equal intensity in sterile and in infected materials. In the second phase the biological catalyst will create an environment with very high electrode potentials, the pH remaining almost the same.

In old plate cultures of *Sphaerotilus* sp. a crust was formed around the bacterial colonies. In certain instances material from these crusts showed, in concentrated solution, a negative pH and potentials of more than $+900$ mV. There are more than 40 ferrous and ferric sulphate minerals described in the literature, and almost invariably they seem to be formed by the oxidation of pyrite in a dry atmosphere.

We can say, therefore, that the desiccation of the bacterial end-products adds a third, final stage to the oxidation of pyrite—a physical phase.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 23

Laboratory Animals Centre (at the Royal Society of Medicine Wimpole Street, London, W.1), at 9.30 a.m.—Symposium on "The Provision of Animals for Cancer Research".

* Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. J. H. G. Lebon and Mr. V. C. Robertson: "Jebel Marra, Darfur, and Its Region".

University of London (at the Wright–Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Norfolk Place, London, W.2), at 5 p.m.—Dr. P. L. Mollison: "The Role of Complement in Blood Group Reactions".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. C. Robertson King: "The Retail Distribution of Electricity". (Last of three Cantor Lectures on "Energy".)

Monday, May 23—Saturday, May 28

Instruments, Electronics and Automation Exhibition (at Olympia, London).*

Tuesday, May 24

University of London (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. M. Blackman: "Some Applications of Electron Diffraction Techniques" (Inaugural Lecture).

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. B. Segre (Rome). "Continuous Variation and Homotopy in Algebraic Geometry".* (Further lectures on May 26 and 30).

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.45 p.m.—Mr. J. S. Wacher: "Recent Excavations at Catterick and Brough-on-Humber".* (Sixth of nine lectures on "Recent Archæological Discovery in Britain". Further lectures on May 31, June 7 and 14).

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Annual General Meeting. 7 p.m.—Mr. R. S. Medlock: Presidential Address.

Wednesday, May 25

Society of Chemical Industry, Nutrition Panel (at 14 Belgrave Square, London, S.W.1), at 4 p.m.—Dr. L. J. Teply: "Foods for the Under-developed Countries".

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "New Semiconductor Devices and their Possible Applications" opened by Dr. A. F. Gibson and Mr. G. King.

Polarographic Society (at the Royal College of Science, Imperial Institute Road, London, S.W.7), at 7 p.m.—Meeting on "Automatic Analysis by Electrochemical Methods".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. G. F. J. Garlick: "Luminescence—The Cold Light of Physics".

Wednesday, May 25—Friday, May 27

Society for the Study of Fertility (at the Royal Veterinary College; Guy's Hospital Medical School; and the Institute of Obstetrics and Gynæcology, Chelsea Hospital for Women)—Annual Conference.

Thursday, May 26

(In the Physiology Lecture Theatre, Guy's Hospital Medical School, London Bridge, S.E.1), at 5 p.m.—Dr. J. Parizek (Prague): "Sterilization of the Male by Cadmium Salts" (Third Oliver Bird Lecture).

Thursday, May 26

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. A. G. Gaydon, F.R.S., Mr. G. N. Spokes and Mr. J. van Suchtelen: "Absorption Spectra of Low-Pressure Flames"; Mr. R. Bralsford, Mr. P. V. Harris and Prof. W. C. Price, F.R.S.: "The Effect of Fluorine on the Spectra and Ionization Potentials of Molecules".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. S. J. Bach: "The Metabolic Fate of Protein-Nitrogen in the Mammal"*. (Further lecture on June 2.)

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. P. Waser (Zurich): "The Cholinergic Receptor".*

Friday, May 27

Institution of Chemical Engineers (at the Imperial College of Science and Technology, Department of Chemical Engineering, Prince Consort Road, London, S.W.7), at 3.30 p.m.—Mr. J. W. Smith: "Heat Transfer to Liquid Fluidized Beds and to Coarse Suspensions Flowing in a Vertical Pipe".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with interests in physical chemistry, preferably in the field of theoretical chemistry) in the Department of Chemistry—The Secretary, The University, Edinburgh (May 28).

Principal Lecturer (with high academic qualifications, some industrial and research experience, and preferably teaching experience) in Industrial Statistics—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4, quoting "D" (May 28).

Assistant Lecturer or Lecturer (with an honours degree in zoology or a veterinary or medical qualification, and a special interest in experimental helminthology) in the Department of Agricultural and Forest Zoology—The Registrar, University of North Wales, Bangor, North Wales (May 30).

Scientific Officer (with a good class honours degree in zoology and some research experience, preferably in soil fauna) at Merlewood Research Station, Grange-over-Sands, Lancs, or Moor House Field Station, Alston, Cumberland, for work on the ecology of moorland invertebrates—The Nature Conservancy (E), 19 Belgrave Square, London, S.W.1 (May 30).

Lecturer in the Department of Mathematical Physics—The Secretary, The University, Edinburgh (May 31).

Lecturers in Experimental and Theoretical Physics—The Secretary of University Court, The University, Glasgow (May 31).

Mullard Research Fellow (preferably with a Ph.D. degree, or with equivalent research experience) in Physics, for research in various branches of solid-state physics with particular reference to defects, semiconductor or surface properties—The Registrar, University College of North Staffordshire, Keele, Staffs (May 31).

Lecturer, Grade II (with special interests in newer palæozoic stratigraphy and palæontology) in Geology—The Registrar, The University, Bristol 8 (June 1).

Assistant Lecturer in Genetics in the Department of Botany—The Registrar, The University, Leicester (June 4).

Demonstrator in Zoology—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (June 4).

Fellow and Lecturer in Philosophy—The Rector, Exeter College, Oxford (June 4).

Lecturer or Assistant Lecturer in Pure Mathematics—The Registrar, The University, Leicester (June 4)

Assistant Lecturer (prepared to teach general invertebrate zoology, other than entomology) in Zoology—The Registrar, University College of North Wales, Bangor, North Wales (June 6).

Lecturer (with special qualifications in educational psychology) in Education—The Registrar, The University Sheffield (June 6).

Chemist, Assistant Experimental Officer or Experimental Officer grade (with a degree in chemistry or equivalent qualification and preferably experience in pesticide analysis) in the Plant Protective Chemistry Section, to assist in studies of pesticides in fruit culture—The Secretary, East Malling Research Station, near Maidstone, Kent (June 10).

Organic Chemist (Ph.D. standard) at the Medical Research Council's Carcinogenic Substances Research Unit, University of Exeter, to work with a team investigating the chemistry of tobacco and tobacco smoke—The Vice-Chancellor, The University, Exeter (June 10).

Research Assistant (with the degree of Ph.D. or about to submit a Ph.D. thesis) in the Department of Chemistry, for work, in collaboration with Dr. J. J. Kipling, involving carbonization of high-molecular weight compounds, graphitization of the resulting carbons, and examination of the physical properties of the product with particular emphasis on adsorption studies—The Professor of Chemistry, The University, Hull (June 11).

Senior Lecturer in Thermodynamics; a Senior Lecturer in Electricity (heavy and light current); and a Senior Lecturer or Lecturer in Fluid Dynamics (hydraulics or aerodynamics)—The Registrar, The University, Leicester (June 11).

Scientific or Technical Assistant (male, preferably with seagoing or diving experience), to assist in a research programme on the biology of the Western Australian commercial crayfish—The Director, Western Australian Museum, Beaufort Street, Perth, Western Australia (June 14).

Lecturer or Assistant Lecturer in Chemistry at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 15).

Lecturer/Senior Lecturer in Pure Mathematics at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 17).

Reader in Physiology at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 21).

Chair of Mathematics in Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Lecturer (with research experience in the biochemical mechanisms of drug action) in Pharmacy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Research Students (2) (graduates or students graduating this year in chemistry, biochemistry or physiology) in the Cancer Research Department, for work on biochemical and immunological aspects of carcinogenesis—The Registrar, The University, Nottingham (June 30).

Reader in Applied Entomology at Imperial College—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 1).

PROFESSOR (specialist in either applied mathematics or theoretical physics) OF APPLIED MATHEMATICS at Rhodes University, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, July 15).

LECTURER IN PHYSICAL METALLURGY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 16).

LECTURER (with qualifications in either pure or applied mathematics) IN MATHEMATICS at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (New Zealand and London, August 8).

BOTANIST (PLANT BREEDER) (with a good honours degree in botany and at least two years postgraduate experience, preferably with perennial crops) in Uganda, to breed locally adapted varieties of Arabica coffee resistant to rust; to investigate compatibility systems; and to conduct variety trials on Robusta and Arabica coffee—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/9/034/T.

EXPERIMENTAL STAFF (with a pass degree or H.N.C., and experience in one or more of the following fields: electronics, vacuum techniques, nuclear counting methods, or general experimental physics), to join a team studying experimental nuclear reactors and carrying out general neutron physics research—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 2632/34.

FISHERIES OFFICER (with a good honours degree in natural science (zoology), experience of the inshore fishing industry, and preferably a knowledge of East Africa) in Tanganyika, for the development of marine or inland native fisheries—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/012/T.

LECTURER (with high qualifications in electronics and communications) IN ELECTRICAL ENGINEERING—The Registrar, The University, Bristol.

MASTER (with an honours degree) TO TEACH PHYSICS up to "A" or "S" level—The Headmaster, Westminster School, 17 Dean's Yard, London, S.W.1.

PLANT PHYSIOLOGIST (with a good honours degree in botany or chemistry with specialization in plant physiology and not less than two years suitable postgraduate experience or training) in Tanganyika, for research work on coffee, with particular reference to over-bearing and plant nutrition, and to collaborate with other specialists—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/026/T.

POSTDOCTORAL RESEARCH FELLOWS IN INORGANIC CHEMISTRY, with special reference to transitional metal complexes and organometallic compounds—Prof. G. Wilkinson, Imperial College of Science and Technology, London, S.W.7.

READER (with the qualifications and experience to direct research and postgraduate work, and to take a leading part in advanced training) IN PHARMACOLOGY—The Registrar, Bradford Institute of Technology, Bradford 7.

RESEARCH FELLOW (with a good degree in electrical engineering, physics or chemistry, and some research or industrial experience) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1.

SCIENTIFIC OFFICER, Grade I (honours graduate in zoology, botany or agriculture, a practical knowledge of modern methods of pest and weed control, and preferably administrative ability) IN THE INFESTATION SECTION, British Railways Research Department, Manchester—Director of Research (British Railways), British Transport Commission, 222 Marylebone Road, London, N.W.1.

SCIENCE IN SECONDARY SCHOOLS IN BRITAIN

UNDER the Government's five-year plan for 'Secondary Education for All', a phrase which seemed to be popular in official circles fifteen years ago, nearly £300 million will be spent on new and improved secondary schools. About 1,000 new science laboratories are being erected and equipped each year, and although most of these will be in new schools, special attention is being given to the needs of existing grammar schools. There has been a steady increase in the number of graduate teachers of science and mathematics in the past few years. But this number is still not satisfactory, and the general level of the qualifications of science and mathematics teachers is even worse. Although it is admitted that there is a position in the grammar school for the lower second-class, the third-class or the pass-graduate, successful science teaching demands a scientific ability and background, cultural in the fullest sense of the term, the incidence of which is not great. A pleasing feature of the present situation is the probability of better standards in some of the training colleges because of the extension of the course to three years.

A recent Ministry of Education pamphlet*, which modestly describes itself as such although it runs to 164 pages, is timely and stimulating although it does not say much that is new. It is written enthusiastically by a group of Her Majesty's Inspectors whose aim is to help to stimulate the better teaching of science. The authors do not make the mistake of trying to provide syllabuses for each type of secondary school, and, although a few matters are selected for detailed consideration and illustration, the treatment of the topics is general. The booklet commences, as does "The Teaching of Science in Secondary Schools" compiled by the Incorporated Association of Assistant Masters and the Science Masters' Association, published some months earlier, with a short history of science teaching in England and a short but very useful account of the English tradition of science teaching. These matters are worthy of serious study, because only by a reasonable assessment of past failures and successes can we hope to build satisfactorily in the future.

Of particular interest is a revealing chapter, which could only have been written adequately by H.M. Inspectors, on conditions under which science is taught in Britain. Then follows a chapter of three pages on the development of children and the teaching of science. This seems to be the core of the whole matter and it will be noticed later. There are useful chapters on the design of science courses and some hints on the approach to general science.

The book makes a plea for a more honest, stimulating and pedagogical approach to what is so often wrongly called experimental work in schools. There are objections to heuristic methods in their crudest forms, but the ideas of H. E. Armstrong, a remarkably fine teacher of chemistry, should be considered in relation to modern requirements and possibilities.

The investigation of some simple problems in dynamics and apparent solar diameter, chosen, no doubt, to escape for a while from the beaten track of elementary science teaching, have been given a detailed treatment and illustrated with excellent photographs and diagrams.

The teaching of biology, chemistry and physics are succinctly reviewed in order. Part 4 of the book deals briefly with practical considerations of immediate importance: the design of laboratories, laboratory assistance, apparatus-making and suitable tools for this task. Once again, the qualities of a good science teacher are set out. The interesting thing about this is that it has been said so often before and in the same terms, but with little effect. Perhaps it is pessimistic to suggest that few science teachers recruited since the end of the War will meet the desiderata so ably set forth.

It may be hypercritical to note such a sentence as: "It is simple to tow a trolley fitted with a speedometer by means of a spring balance" and to call a difference of 5 per cent in the results of simple astronomical observations a close agreement. With so many topics briefly considered in so short a space, it has been difficult to avoid occasional superficiality. Chapter 10, a short essay on scientific method and the place of mathematics in it, is brilliant. There is a great deal of useful matter in this little book, and much of its worth only reveals itself by a second careful reading. It is the product of the mature thought of many able minds and is warmly recommended not only to actual and potential teachers of science and educationists in general but also to all those who have any interest in science. With all this, however, there is still one important matter—in fact, the most important—on which a little has been said in Chapter 4 and, indeed, little is known. Under the Education Act of 1944, secondary education was divided into grammar, technical and modern. The grammar schools continued on the way which had been laid down for them by the syllabuses of the external examinations, with perhaps a slight tendency to more enlightenment in methods and content in science teaching, but with still too great a stress on the 'facts' of elementary science and the repetition of simple, well-tried demonstrations, usually with much dictation of notes. Some schools did and do make an earnest endeavour to get the best out of science teaching by considering the nature of the study, the planning and carrying out of experiments, the methods of dealing with observations, the problems of error and confidence, the applications of science, the scientific spirit and so on; but too often science teaching was measured by its efficiency in producing passes at Ordinary Level, and in the sixth form at Advanced Level, in the General Certificate of Education examination; and in many schools, particularly girls' schools, it was not efficient even there.

---

* Ministry of Education. Pamphlet No. 38: Science in Secondary Schools. Pp. vi+164+6 plates. (London: H.M. Stationery Office, 1960.) 6s. net.

The secondary technical school in Britain has suffered through lack of equipment and teachers, but in the former there is much improvement. Selection for secondary technical schools is largely unsatisfactory, since the more intelligent children among those who fail to secure places in grammar schools are sent to technical schools. A consideration of the selection problems for children suitable for technical education is long overdue. Finally, there are the secondary modern schools. It is not unfair to say that, even with a certain tradition inherited from the central schools, they have largely failed to find a philosophy or even a scheme of work for themselves. No doubt the problems of staffing such schools with men and women with adequate science and teaching qualifications have been insuperable. Nevertheless, in view of some of the recommendations of the recent Crowther Report, the future of the secondary modern schools is of paramount importance. There can be little doubt that their comparative failure to establish themselves educationally and socially has led to cries, with political overtones, for comprehensive, bilateral and other schools.

The science-teaching triangle is child, teacher, equipment. The best equipment in the world—and much of it in British schools is surprisingly good—does not make a good teacher; and even a good teacher will not improve the intelligence of a child, even if good teaching may awaken interests and may apply whatever natural intelligence is found in the pupil to the best advantage.

Much research is necessary concerning the child-mind in relation to science, and should be undertaken by institutes of education and postgraduate teachers. Various natural bents, intelligences and levels of maturation will have to be considered in relation to the scope and content of science syllabuses, the origins of interest, and the methods and techniques of teaching—and all this in relation to the various aims which educationists have in mind, in teaching science at all.

THE DILEMMA OF THE FAR EAST

Population and Progress in the Far East

By Warren S. Thompson. Pp. ix+443. (Chicago: University of Chicago Press; London: Cambridge University Press, 1959.) 56*s*. 6*d*. net.

THIS is an important book about an important subject—the struggle of half of the world's people to keep production ahead of population growth. Its merit lies essentially in the wealth of information and analysis it supplies about the basic resources, technologies, economic policies and social customs which governments of Asian countries are desperately attempting to manipulate to break through the Malthusian barriers of subsistence. Chapter by chapter, Prof. Thompson lays out the patterns in Japan, India, China, Pakistan, South-east Asia and Taiwan and Korea

The reader naturally hopes that out of the great knowledge which Prof. Thompson displays there will emerge a pattern of hope; but his conclusions are sober, if not gloomy. He warns that even Japan, now generally listed as Asia's most prosperous country and the one clear case of population control, is yet in a precarious position, with a cultivated area still less than in 1940 and a trading area reduced to "about what it was in 1872". Compared with the rest of Asia, Japan is well advanced along the roads of both economic growth and demographic transition. Not so India, where the author concludes that of the vast uncultivated areas of 124 million acres, probably only 25 million are cultivable, or only enough to take care of present rates of population growth for some 4 or 5 years. However, Prof. Thompson does admit some prospect of increased productivity and of raising investment to some 10 per cent of national product, or sufficient to cope with a population increase of about 1·7 per cent and to bring some slight rise in living standards. But short-run gains will become losses unless the rate of population growth can be slowed down.

As for China, Prof. Thompson also doubts some of the more optimistic claims about unused resources; and emphasizes that if the 1953 census and subsequent official pronouncements about the annual rate of population growth of some 2 per cent are correct, the Chinese problem may prove even more intractable than that of India, although China has almost certainly a much greater area of cultivable but unused land than India.

On the general issue of how to achieve a successful take-off in the process of economic growth, Prof. Thompson shows himself to be an ardent agricultural democrat and traditionalist. His warnings against undue expectations from innovations, over-capitalization in enterprises that could best be carried out by more intensive use of labour, and insufficient attention to the strength of traditionalism leading to false optimism about the speed with which controls over the rate of population growth can be introduced, are all timely. Nevertheless one feels that he may be a little too conservative here, considering the rate of change that has occurred, and is so clearly still occurring, throughout the whole Asian and African world.

The biggest issue is whether the processes of economic growth and population control can be accomplished within a democratic framework. Prof. Thompson looks with hope to the Indian pattern, although even here he fears there may be too much emphasis now upon industrialization and not enough upon production of food and fibres, which he considers "will almost certainly be the chief source of capital" in all Asian countries. I share his hope that these great issues will be resolved within democratic frameworks; yet there is no proof that they will be, and we have to face the issue that, however much we dislike their political system, the Chinese do seem to be making as much progress as the Indians in trying to resolve the Malthusian dilemma of keeping the tortoise of production ahead of the hare of population growth.

Prof. Thompson's informative and thoughtful book is warmly recommended to those who want to think on the world's other great explosion—population growth. W. D. BORRIE

MAN AMONG THE PRIMATES

The Antecedents of Man

An Introduction to the Evolution of the Primates. By Prof. Sir Wilfrid E. Le Gros Clark. (Edinburgh University Publications: Science and Mathematics Texts, No. 2.) Pp. vii+374. (Edinburgh: At the University Press, 1959. Distributed by Thomas Nelson and Sons, Ltd., 1959.) 21*s*. net.

LE GROS CLARK'S "Early Forerunners of Man" (1934) is one of the basic studies in primatology; but it has long been unavailable, the stock having been destroyed by enemy action during the War. It is also now seriously out of date because of the great increase in knowledge of fossil primates during the past quarter-century. The Munro Lectures at the University of Edinburgh in 1953 gave Le Gros Clark occasion to review the whole subject, and he has now published what is essentially a revision of the earlier book, incorporating the substance of these lectures and also discoveries made since 1953.

"The Antecedents of Man" covers the same field and has nearly the same organization as "Early Forerunners of Man". The bulk of the book, as before, comprises a series of chapters on the comparative anatomy of the dentition, skull, limbs, brain, special senses, digestive system, and reproductive system of the primates. All are treated from a taxonomic and phylogenetic point of view. Fossil evidence on the hard parts and endocranium is included. These chapters do not differ greatly from the earlier version but have been well brought up to date. A wholly new introductory chapter on modes and processes of evolution and the interpretation of pertinent evidence is a useful and welcome addition. An older chapter on the reference of the tree-shrews to the primates, a radical idea in 1934 but now widely accepted, has been eliminated, and the evidence has been given where appropriate in other chapters.

The revised final chapter on evolutionary radiations of the primates particularly reflects new palæontological discoveries. Among the earlier forms there is less insistence on a sharp tarsioid-lemuroid dichotomy and on derivation of anthropoids from definite tarsioids. Among the later forms, discovery of the australopithecines and recognition of their near-ancestral relationship to man has made the greatest difference. Le Gros Clark was among the first to recognize that relationship, and he has maintained it in the face of polemic criticism. He may be excused a measure of satisfaction, here only faintly expressed, that time and further discoveries have proved him right in the opinion of the great majority of his colleagues. Another extremely important body of discovery since 1934 is abundant Miocene primate material found by Leakey in central Africa and described in large part by Le Gros Clark himself.

The taxonomy of early (Palæocene to Oligocene) primates and their relationships to various primitive insectivore-like groups is now again in a fluid state. From that point of view, this is an unfortunate time to review the group, and this part of the discussion is already becoming out of date. However, one can scarcely wait for study to stop before summarizing past results.

The book is not written down to a popular audience, but it assumes only minimal knowledge of anatomy and zoology. It might, indeed, be considered somewhat elementary for use as a text-book as suggested by author and publisher. For that and also other purposes the absence of a formal reference classification is unfortunate.

There are numerous books, even good books, on fossil man and human origins. This is the only book that places man in true perspective within the whole order Primates and its seventy million years of history. It is an excellent synthesis and summary, and it is warmly recommended. G. G. SIMPSON

ASPECTS OF AERONAUTICAL SCIENCES

Advances in Aeronautical Sciences

Proceedings of the First International Congress on the Aeronautical Sciences, Madrid, 8–13 September, 1958. Edited by Th. von Kármán, A. M. Ballantyne, R. R. Dexter, H. Blenk, H. L. Dryden and M. Roy. Vol. 1: Pp. viii+1–562. Vol. 2: Pp. viii+563–1144. (International Series on Aeronautical Sciences and Space Flight. Division 9: Symposia.) (London and New York: Pergamon Press, 1959.) 200*s*. net the set of two volumes.

THE papers recorded in these two volumes were presented at the first international congress organized by the newly formed International Council on the Aeronautical Sciences, and it is hoped that similar meetings will be sponsored in different countries every two years or thereabouts.

It would be an impossible task for any one reviewer to comment with authority on more than a few of the papers presented, since they cover an immensely wide range of aeronautical science. Forty-six in number (eight in French, four in German, one in Spanish, the remainder in English) they embrace, *inter alia*, mathematics and materials, medicine and mechanics, mixed flows and magnetohydrodynamics. There are general surveys of fields of knowledge, and original contributions; the speed-range covered runs from the zero forward velocity of a vertical take-off aircraft to the escape velocity of a satellite. I can therefore do no more than skip through the volumes, noting here and there a paper of particular interest, and finally giving an overall impression.

In the formation of the International Council on the Aeronautical Sciences and the promotion of the congress, financial assistance was received from the Guggenheim Fund for Aeronautics; it is therefore appropriate that the Proceedings open with the first Daniel and Florence Guggenheim Memorial Lecture. It was delivered by Th. von Kármán, and entitled "Some Significant Developments in Aerodynamics since 1946". It gives a very readable survey of the subject, ranging through supersonic and hypersonic speeds to Newtonian flow, and then over boundary-layer theory and turbulence. One plea should be quoted: "I believe that a systematic nomenclature and classification of these new branches of combined fluid mechanics, electromagnetic theory, and thermodynamics is yet lacking". One may say 'amen' to that.

There follows a group of papers dealing with various problems of high-speed flight—design, navigation, propulsion, the theory of hypersonic flow; an informative little essay from the pen of Lighthill on the dynamics of a dissociating gas is followed by a substantial paper on American experimental work on hypersonics. Next, three papers concerned with thermal effects on structures and one on oscillatory transonic derivatives appear (the authors being respectively Dutch, Italian, French, and Swedish). The first volume is completed by a dozen papers in groups, dealing with heat transfer, noise (both physical and bio-acoustic), and automatic control.

The second volume opens with a series of substantial papers on boundary layers (particularly boundary-layer control). Next, two general papers survey respectively the subjects of aero-elasticity and of hypersonic flow; they are followed by two papers on ring aerofoils. An interesting Russian contribution from Dorodnicyn deals with the analytical difficulty of calculation in the transonic region, when the governing equations are changing from elliptic to hyperbolic type. Vertical take-off provides the subject for the next group; materials for heat resistance are then discussed in three papers. Two papers on telemetry, three on aviation medicine matters, and three on propulsion methods for astronautics (including ionic propulsion) conclude the volumes.

The general impression gained from browsing through these volumes is entirely favourable. To weld such a variety of papers from so many different sources into a coherent whole must have presented the editors with a major task; they are to be congratulated on the result. The volumes are admirably printed, and only one or two misprints were noticed. As regards the papers themselves, I do not feel competent to judge more than a few, which I found of high standard; in the many other fields I found much of interest and many papers which invite a second more careful reading. A. R. COLLAR

PROGRESS IN METAL PHYSICS

Progress in Metal Physics
Vol. 7 (1958). Pp. viii+408. 110*s*. net.
Vol. 8 (1959). Pp. viii+330. 90*s*. net. Edited by Dr. Bruce Chalmers and Dr. R. King. (London and New York: Pergamon Press.)

TO say that these two volumes maintain the standard, and the interest, of their predecessors in this series is in itself high praise which is fully deserved. To the authors of the articles—and to the editors it should not be forgotten—are due the thanks of all concerned with the ultimate structures of metals, their transformation by heat or mechanical deformation and their alloys.

Volume 7 contains an account of work on the equilibrium, diffusion and imperfections in semi-conductors, justified, as if this were necessary, by the fact that single crystals of silicon and germanium are now available of a purity and perfection which surpass those of metal crystals "by many orders of magnitude". The paper on the physical metallurgy of titanium alloys is a discussion in terms of the fundamental factors involved, of the question "What additions form useful alloys with titanium ?". It is obvious that the last words in the perennial problems of the thermodynamics and kinetics of martensitic transformations have not yet been said, as is abundantly evidenced by the noteworthy progress made in the past decade, which is excellently summarized here. That that part of the mechanical energy expended in deforming a metal and stored up in the deformed structure is the essential feature of the cold-worked state has, in general terms, been recognized for many years. That it is the cause of the instability of this structure is equally well known. The account, therefore, of the extent to which this qualitative treatment may be developed into a quantitative treatment is to be welcomed. The final article, a second one on the properties of metals at low temperatures, deals particularly with thermal conductivity, on which a large amount of work has been done, and on certain mechanical properties.

Volume 8 commences with still a third review in this series of the work-hardening of metals. Despite this, the account of new work extends to some hundred pages with getting on for two hundred references. Allied to this is an article on X-ray studies of deformed metals. The fact that metallic crystals are never perfect has long been known, and an account of the defects in pure metals discusses the subject from the point of view of modern knowledge. "Ten years of fairly intensive work has yielded a moderately complete experimental picture of copper and gold, and the theoretical estimates are apparently reasonably accurate", but "it would be unreasonable to expect to find any easy way of extending our knowledge to other metals".

Two articles remain to be mentioned, one a very welcome discussion on grain boundaries. After a period some thirty to forty years ago when these boundaries were the focus of metallographic thought, this, under the influence of the then new X-ray techniques, moved over to the structure of the crystals themselves. In view of the profound importance of the grain boundary on the properties, it is a healthy sign that their nature, still very far from being fully understood, should once again be a subject of investigation. Finally there is an account of the substructures in crystals grown from the melt, a matter of most obvious significance. The cellular structure on the solid-liquid interface of such a crystal of tin, Fig. 15, is so full of interest that one is led to wonder whether the old Quincke hypothesis might not repay renewed examination at the hands of a modern physical metallurgist.

An almost incredible amount of work is summarized in these volumes, and the need of men well-versed in such matters who can, and are willing to, apply this knowledge to modern industrial needs requires no emphasis. F. C. THOMPSON

FLAME AND EXPLOSION OF GASES AND VAPOURS

Explosions, Detonations, Flammability and Ignition
Part 1: Selected Analytical Studies on Explosions, Detonations, Flammability Limits, and Ignition of Gases, and on Heterogeneous Burning. By Prof. S. S. Penner. Part 2: Experimental and Theoretical Studies of Flammability, Ignitibility and Explosion Prevention. By B. P. Mullins. (AGARDograph No. 31.) Pp. xi+287. (London and New York: Pergamon Press, 1959. Published for and on behalf of Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization.) 70*s*. net.

THIS work is largely an account of recent advances in fundamental knowledge of initiation and propagation of flame in engines powered by gaseous and liquid fuels. Other subjects, such as the extinction of flame and the explosion of clouds of certain metallic powders and coal dust, have comparatively brief notices. Solid explosives are not included.

The work has two principal foci, one being the major interests of a professor of jet propulsion and the other of an officer of the National Gas Turbine Establishment. The two parts are written almost independently, and might well have been published separately. Indeed, the introduction to Part 2 claims that "it is often evident that a semi-empirical thermal approach can yield results which are much more accurate than a basic theoretical treatment which can usually only indicate orders of magnitude". A closer correlation of theory and experiment may be possible some day, but the authors, in their joint general introduction, say that "much more work must be done before we arrive at anything resembling a complete theory of, for example, flammability limits and ignitibility, particularly in heterogeneous systems", and hope that their monograph "will stimulate fresh ideas and indicate areas of combustion research in which future effort might be directed fruitfully".

Both parts of the book are based on a detailed knowledge of recent advances (up to about 1958) in the study of flame and explosion in gases, vapours and mists. The authors quote from their own contributions, some of which have not previously been published, and from available papers from many sources, including some important Russian work. The bibliographies seem to be thorough and carefully prepared; and the few errors that I have noticed (for example, the mis-spelling of the names of Blecher, Barth and Couriot) will not seriously inconvenience anyone.

The reference (p. 113) to "Semenov's original postulate that an ignition temperature is that temperature at which the initial loss of heat due to thermal conduction etc. is equal to the heat liberated at the same time by the chemical transformation" must have been written in ignorance of Van't Hoff's postulate ("Etudes de Dynamique Chimique", 1884), which reads "Le température d'inflammation est celle à laquelle la perte initiale de chaleur, dûe à la conductibilité etc., est égale à la chaleur que produit en même temps la transformation".

Although the chief value of the book is its review of the researches of the past ten years or so on gaseous combustion in relation to engines, it will be of much value to a wider circle concerned with the use or suppression of flame. The book is not for beginners, who have (as the authors repeatedly indicate) the works of Bone and Townend, Jost, and Lewis and von Elbe in which to find summaries of the older researches on this very intricate subject.

H. F. Coward

ARTIFICIAL INSEMINATION IN CATTLE

Lehrbuch der Rinderbesamung

Grundlagen, Technik, Organisation und züchterische Probleme der Samenubertragung beim Rind. Von Dr. Karl Eibl. Pp. xv+485. (Berlin und Hamburg: Verlag Paul Parey, 1959.) 74 D.M.

This book is a thorough and detailed compilation of facts from the literature about artificial insemination in cattle. While a list of the main books on the subject is given, no references to original papers are listed although names and dates are given in the text. It is arranged in six sections the scope of which are indicated by some of the examples quoted below. Section 1 deals with the anatomy and histology of the male organs. The structure of spermatozoa, the pathology of spermatogenesis and abnormal forms are well illustrated. Different forms of artificial vaginas and electro-ejaculation are described. Methods of semen examination such as the impedance test, staining for live and dead sperm and for fructolysis are outlined. In Section 2 the female organs are described. A good illustrated account is given of the development and timing of the fertilized egg from ovary to uterus. Conception rates are also dealt with. Section 3 outlines the history, development and present state of artificial insemination in different countries. Various methods for proving bulls for milk and type are also described. The practical problems of the organization of artificial insemination stations are given in Section 4: plans are given for the layout of centres. Methods of feeding and examining bulls for disease and impotency are included. The significance of testes volume is also discussed. Among the various things described in Section 5 are the different dilutors and the blood grouping of sires and their offspring. Details and illustrations of the apparatus used in the deep-freezing of semen are given and semen banks are discussed. Reference is also made to the carbon dioxide method of storage at room temperatures. In Section 6, and also elsewhere, the problems concerned with semen infected with *Vibrio* or *Trichomonas* are discussed.

This is a very useful book to consult on all questions of artificial insemination in cattle. J. Hammond

ADVANCES IN VETERINARY SURGERY

The Veterinary Annual, 1959

Edited by W. A. Pool. Pp. xxiv+363+36 plates. (Bristol: John Wright and Sons, Ltd., 1959.) 42*s*.

No veterinary periodical has as yet, as a matter of editorial policy, sought to provide a comprehensive selected abstract service. "The Veterinary Annual" aims to satisfy this need, and the first edition has made a very good start.

It must be judged mainly on the adequacy and topicality of its reviews of the current literature, which provide the main bulk of the text. The literature of 1958 and part of 1959 is covered in most of the sections as topically as any annual published in early 1960 can be. The reviews cover the diseases related to bacteria and fungi, to protozoa, viruses and parasites, nutritional and metabolic disorders, reproduction and reproductive disorders, neoplasms, radiation and radiology, pharmacology, toxicology, physiology, surgery, technique and apparatus and public health.

The editor, W. A. Pool, has contributed several sections himself, and these are a good indication of the high standard he is setting. He has also avoided, and restrained his contributors (one or two apparently with some difficulty) from, covering up a deficiency of research results by theoretical exercises which may only mislead the veterinary practitioner who is not so well informed on these matters. Indeed the mere fact that these deficiencies due to lack of progress in research are obvious is to the credit of the editor and his contributors.

One major deficiency is the lack of reports of clinical trials of new drugs. This is emphasized by the list of fifty new drugs and appliances together with manufacturers' descriptions—many of which may never be competently evaluated.

Besides the very adequate review of the current literature there are a number of special articles describing veterinary work in the United States of America, Denmark, Sweden, Canada, Australia, New Zealand, Central and South Africa. That by Smithcors about the United States of America is an excellent introductory article which sets a very high standard for those to follow. Various aspects of veterinary practice in Great Britain are also covered under the headings of country practice, horse practice and small-animal practice. Here the contributors are too vague and in none does the standard approach that of Smithcors or of the introduction to greyhound racing by Bateman. In the next edition the editor might pay attention to some of the subjects discussed in his own preface. Contributions relating new methods of husbandry and feeding to the wide range of standards of management existing in Great Britain would certainly become a most fruitful new venture. It should be noted that the small list of new publications included in the book cannot be considered by any means exhaustive.

This annual is strongly recommended to all those many veterinary surgeons and field research workers who lack adequate library facilities or a comprehensive abstract service. G. N. GOULD

STEROID CHEMISTRY

Steroids

By Prof. Louis F. Fieser and Mary Fieser. Pp. xvii+945. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1959.) 144*s*. net.

THIS book represents the fourth edition of one first published in 1936 under the title "Natural Products Related to Phenanthrene", the third edition of which was published in 1949. The present book deals entirely with the chemistry of the steroids, which have become by far the most important group of naturally occurring phenanthrene derivatives.

The reviewer's task is a pleasant one because this is a superb presentation, both for the specialist and for the general reader. Biological and commercial interest in the steroids over the past ten years has stimulated a vast amount of chemical research. This might have proved dull, but in fact it has been intimately connected with new applications of physical techniques (for example, infra-red spectra and rotatory dispersion), new theoretical ideas such as conformational analysis, and the development of new reagents. It might fairly be claimed that the steroids have set the pace for the development of alicyclic chemistry over the past decade.

This book can be read with pleasure and profit by workers in any field of organic chemistry, including the specialist on reaction mechanisms, the synthetic organic chemist, the worker who is concerned with the application of new instrumental methods, etc. Not only does this book review most admirably the literature of the subject; but also the authors in many places add their own interpretations and generalizations—and furthermore they pose new problems for research.

All aspects of steroid chemistry are covered, and although the book does not pretend to be a complete catalogue of all the facts, the wealth of detail is such that it may be feared that many research students will be tempted not to bother to look at the original literature.

The general chapters of the book cover the following topics: Chapters 1–2, introduction and structure of the steroid skeleton; 5, physical methods of characterization; 6, oxidation; 7, enes and ols; 8, ketones; 9, displacements and rearrangements; 10, stereochemical correlations and conventions.

The specialized chapters deal with all the main groups of steroids as follows: Chapter 4, vitamin D; 11, sterols; 12, methylsterols (including the tetracyclic triterpenoids); 13, biosynthesis of cholesterol; 14, bile acids and alcohols; 15, œstrogens; 16, androgens; 17, progestogens; 18, homo- and nor- steroids; 19, adrenocortical hormones; 20, cardiac-active principles; 21, sapogenins; 22, alkaloids.

The book is lavishly illustrated with structural formulæ, many of them three-dimensional. A pleasant feature is the inclusion of many personal notes about workers in the field; such insertions would be annoying if they took the place of good factual and theoretical information, but when they are added to a fine scientific presentation, they contribute greatly to the interest of the book.

One of the most important facts about this book is that it is so up to date. The date of publication in the United States was July 1959; there are many 1959 references, and others to work then unpublished. Many monographs to-day suffer so much from serious delays in editing, printing, revision, etc., that this book must provide authors and publishers with a model of what can be achieved; typographical accuracy and the clarity of the formulæ leave nothing to be desired.

The more one reads of the book the more one is amazed at the way in which the two authors have combined a broad view of the subject with a wonderful grasp of detail. It is significant that in a book of 900 pages they have not followed the common trend of making it a collaborative effort. They have, however, obtained the help of colleagues in the field in another way; the entire manuscript was read by six steroid chemists outside the authors' laboratory; individual chapters and sections were sent for comment to nearly every senior worker in each special branch of the field, and the authors generously acknowledge the very valuable help of these colleagues.

If I may offer one or two suggestions regarding further improvement of the book in its fifth edition, they are the following: the subject index, although very full, might be extended by the inclusion of an index of formulæ of the pattern used in *Chemical Abstracts*, and also an index of reactions; this might be of the type used in Theilheimer's "Synthetic Methods", or perhaps it would be more popular if it did not need a special technique for decoding. The authors have indexed some classes of reaction, including oxidation, reduction, hydrogenation, but not, for example, hydrolysis. Another useful addition to the index would be the names of 'classes' of compounds, such as glucuronides and sulphates.

All steroid chemists will be still further indebted to Prof. and Mrs. Fieser for this wonderful achievement, and it is hoped that many other chemists will take advantage of the mass of information and ideas which is laid before them in this book.

The minor criticisms of the index are rather like the comments of the traveller who directed attention to the ticking of the clock in a Rolls-Royce—for this is indeed a Rolls-Royce among monographs of organic chemistry. W. KLYNE

Applied Hydrodynamics

By H. R. Vallentine. Pp. viii+272. (London: Butterworths Scientific Publications, 1959.) 50*s*.

THIS is a text-book not so much of applied hydrodynamics as of classical theoretical hydrodynamics in an accessible form for application. It is meant for students of engineering and physics as well as applied mathematics.

The mathematics of the subject is expounded in some detail. A student with limited mathematical ability will probably find enlightenment here on subjects about which he would learn little from a more concise account, though occasionally he may have difficulty in seeing the wood as well as the trees.

In an introductory chapter, readers are forewarned of the important differences between inviscid and real fluid-flows. This is welcome. The matter might reasonably have been given more emphasis throughout the book, and in a future edition the apparent identification of near-irrotational flow outside boundary layers with turbulent flow ought to be corrected.

There is a chapter on the numerical and experimental-analogy methods for solving Laplace's equation. Here and elsewhere seepage problems are included among the illustrations; these help to justify treating solutions for boundaries at which separation would occur in ordinary fluid-flow at high Reynolds numbers. Aerofoil and wing theory get less attention than they deserve, apart from aerofoils obtained by conformal transformation of circles.

The book will probably be most useful as a hydrodynamics supplement to one of the better of the available engineering text-books of applied fluid mechanics, to be dipped into as required. Its readers should be well prepared with an understanding of real fluid flow, for while the reminders in it of the realities of applied hydrodynamics are useful, they are not complete enough to stand alone. E. P. SUTTON

British Caenozoic Fossils

(Tertiary and Quaternary). Pp. vi+130 (44 plates). (London: British Museum (Natural History), 1959.) 6*s*.

THERE has long been a need for some kind of comprehensive yet concise handbook illustrating the fossils most commonly found in the various strata of Great Britain. "British Caenozoic Fossils", prepared by the staff of the Natural History section of the British Museum, is the first of a series which will eventually embrace also the Mesozoic and Palæozoic fossils of Britain, and will be widely welcomed. The present volume contains line drawings of 354 Tertiary and Quaternary fossils, together with tables giving their geological distributions and a coloured map showing the principal fossiliferous localities.

The aim of the series is modestly described in the preface as being "to enable the young, or those without experience, to know what fossils they may expect to find, or, even more important from our point of view, to identify for themselves those they have collected"; but there can be few mature professional geologists in Britain who would not be glad to have this book on their shelves or, more to the point, in their pockets when in the field. For the latter purpose the book is ideal; it is compact (approximately 8½ in. × 5½ in.), and clearly printed on strong paper which is unlikely to be ruined by the occasional spot of rain. The drawings are a delight to the eye, and the typography and layout show a concern for clarity and style in every detail which is all too rare at the present day, and surely unequalled in a book of this price. The only criticism which might be levelled at it is that a work of such excellence deserves a more robust and attractive cover. The companion volumes will be eagerly awaited.

Organic Syntheses

Vol. 39. Edited by Max Tishler. (An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals.) Pp. vii+114. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 32*s*. net.

OVER a long period a large number of the more familiar organic chemicals have been dealt with in this annual publication of satisfactory methods for their preparation. The later volumes have accordingly contained a larger proportion of more specialized structures, many of which were unknown at the inception of the series. The great diversity of organic types represented is well illustrated in the present selection of 31 synthetic preparations, including such items as benzeneboronic anhydride, di-*n*-butyldivinyltin, 9-methylfluorene, several derivatives of furan, and the heavily unsaturated alcohol, HC ⋮ C·CH(OH)·CH : CH·Ph, resulting from the interaction of ethynylmagnesium bromide and cinnamaldehyde. An interesting pair of stereoisomers is provided by the low-melting and high-melting forms of 9, 10-dihydroxystearic acid, prepared from oleic and elaidic acids respectively.

The subject index to Volume 39, occupying 34 pages, is a cumulative one, comprising material from volumes 30–39. All the entries in the preceding 29 issues are indexed in Collective Volumes 1, 2, and 3: details of any specific substance are therefore easy to trace. It is almost needless to add that this invaluable series continues to maintain its high reputation for accuracy and reliability. JOHN READ

Glutathione

Edited by E. M. Crook. (Biochemical Society Symposium No. 17, held at Senate House, University of London, February 15, 1958.) Pp. v+116. (Cambridge: At the University Press, 1959.) Cloth 22*s*. 6*d*.; Paper 15*s*.

THE ubiquity of glutathione in living organisms has prompted its widespread study and makes opportune the publication of this symposium, which includes much work carried out after the Ridgefield Symposium of 1953, also entitled "Glutathione". There is no overlap in the contributions to the two symposia, and the present symposium is characteristically different from its predecessor also in presenting a major part of its information in terms of the organisms or organs in which the behaviour of glutathione has been studied. There are considered successively the tissues of plants, of animals, neural tissues, and the lens of the eye. In each of these contributions the reviewers (L. W. Mapson, P. C. Jocelyn, H. McIlwain and S. G. Waley) place their own investigations in a wider setting of the biochemistry of the system concerned. Contributions on the chemistry and analysis of glutathione (F. A. Isherwood, C. G. Thomson and H. Martin) and on its role with other thiols in radiation damage (D. B. Hope) complete the Symposium. It is regretted that there is no index.

COMMUNICATIONS FROM SUPERIOR GALACTIC COMMUNITIES

By Prof. R. N. BRACEWELL

Radioscience Laboratory, Stanford University, California

SINCE Morrison and Cocconi[1] published the suggestion that there might be advanced societies elsewhere in the Galaxy, superior to ourselves in technological development, who are beaming transmissions at us on a frequency of 1,420 Mc./s., Drake[2] has described equipment under construction to look for such transmissions. The confidence necessary to commence actual observations is based on an opinion that planets are a common by-product of the formation of stars. One argument among others is that stars of spectral type later than $F5$ have low angular momenta, just as the Sun has; and in the case of the Sun we know that it is because the momentum (98 per cent of it) resides in planets[3]. Of the thousands of millions of planets in the Galaxy likely to be situated similarly to the Earth in relation to their star, it is hard to dismiss the possibility that some have more advanced civilizations than ours. In view of the acceleration with which technology develops, advanced societies could be incredibly more advanced.

Any simple test of this possibility would be well worth while. Drake plans to look at τ Ceti and ε Eridani. Of the list of likely neighbouring stars given by Morrison and Cocconi, these two, and ε Indi, are the only ones left when we eliminate double stars. Because of orbital perturbations, the planets of double stars are, with some exceptions, not expected to possess equable climates over the geological periods deemed necessary for evolution[4].

But do we really expect a superior community to be on the nearest of those stars which we cannot at the moment positively rule out? Unless superior communities are extremely abundant, is it not more likely that the nearest is situated at least ten times farther off, say, beyond 100 light years? Let us assume that there are one thousand likely stars within the same range as the nearest superior community. This makes it hard for us to select the right one. Furthermore, if this advanced society is looking for us, we can only expect to find them expending such effort as they could afford to expend on the thousand likely stars within the same range of them. It does not seem likely that they would maintain a thousand transmitters at powers well above the megawatt estimated by Drake as a minimum for spanning only 10 light years, and run them for many years, and we could scarcely count on them paying special attention to us. Remember that throughout most of the thousands of millions of years of the Earth's existence such attention would have been fruitless.

Would not this other more advanced society, on the contrary, be doing what we ourselves are now discussing and are on the point of doing, probably during this century, namely, sending probes to nearby stars. Their exploration and other activity would be intense in their immediately neighbouring planetary systems. Beyond their immediate neighbourhood, it might be feasible for them to spray some number of suitable stars, say, one thousand, with modest probes. Each probe would be sent into a circular orbit about one of the thousand stars, at a distance within the habitable zone of temperature. Armoured against meteorites and radiation damage, and stellar powered, the probes could contain durable radio transmitters for the purpose of attracting the attention of technologies such as ours.

Using this plan, our hypothetical advanced neighbours could lay down a stronger signal here than they could with a home-based transmitter handicapped by inverse-square attenuation over interstellar distances. They would also eliminate their dependence on our ingenuity in selecting the right star and the right wave-length.

For this reason we might better devote our efforts to scrutinizing our solar system for signs of probes sent here by our more advanced neighbours. In this way we would be effectively paying attention to all stars capable of reaching us. We need not expect, however, that any community other than the nearest is trying to reach us, because the superior communities throughout the galaxy are probably already linked together into an existing galaxy-wide chain of communication. They will act in concert and avoid duplication in searching. Our impending contact cannot be expected to be the first of its kind; rather it will be our induction into the chain of superior communities, who have had long experience in effecting contacts with emerging communities like ours.

For suggestions as to how the superior communities may detect us, consider what we might do to detect them. A very good first project for us, when we come to probe outside the solar system, would be to seek the presence of technological development on τ Ceti and ε Eridani by means of a probe that would listen for the existence of monochromatic radio-communication, and report back by star-to-star relay. We would see whether there is in those solar systems a radio-frequency line emission spectrum such as the Earth now emits. It is possible, in fact, that the hypothetical feelers sent out in large numbers by our nearest superior community did no more than listen for this radiation. If so, a positive answer could have been on the way back to the home star several decades ago, and we may look forward in due course to the arrival of a more sophisticated mission.

However, since interstellar transfer of material things is time-consuming, and transfer of information is in any event more important, it would be commensurate with the effort of delivering a material probe into our solar system if the very first probe sent here contained a quite elaborate store of information and a complex computer, so that it could not only detect our presence, but could also converse

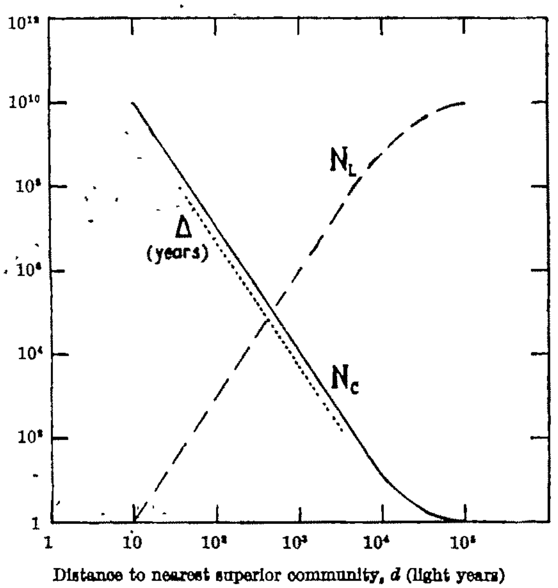

Fig. 1. N_C, total number of communities in the galaxy the technology of which is superior to ours; N_L, total number of likely stars out to a distance d; Δ, average life-time of a superior community

with us. Such a probe may be here now, in our solar system, trying to make its presence known to us. For this purpose a radio transmitter would seem essential. On what wave-length would it transmit, and how should we decode its signal? To ensure use of a wave-length that could both penetrate our ionosphere and be in a band certain to be in use, the probe could first listen for our signals and then repeat them back. To us, its signals would have the appearance of echoes having delays of seconds or minutes, such as were reported thirty years ago by Størmer and van der Pol[5] and never explained.

To notify the probe that we had heard it, we would repeat back to it once again. It would then know that it was in touch with us. After some routine tests to guard against accident, and to test our sensitivity and band-width, it would begin its message, with further occasional interrogation to ensure that it had not set below our horizon. Should we be surprised if the beginning of its message were a television image of a constellation?

These details, and the matter of teaching the probe our language (by transmitting a pictorial dictionary?), are fascinating but present no problems once contact has been made with the probe. The latter is the main problem. The important thing for us is to be alert to the possible interstellar origin of unexpected signals. We must avoid relegating them, if they are there, to the fate of the very strong emissions from Jupiter (of the order of 1,000 megawatts per Mc./s.) which were heard and ignored for decades[6].

If after a few years of careful attention we find no signs, radio or other, of such probe, we shall have to admit the possibility that our nearest superior community is beyond the range where attempts at contact with us would be assured of much certainty of success.

To survey the possibilities of there being a superior community within reaching distance of us, consider Fig. 1, which shows the number of superior communities in the Galaxy, N_C, plotted against the distance to the nearest superior community, d, in light years. This graph is obtained from the broken curve which shows a quantity N_L, the number of likely stars at a range less than d. By likely stars I mean those 5 per cent[4], here taken as 10^{10} in number, that cannot be ruled out at present as unsuitable to support life. The curve is based on a galactic mass distribution model and cannot be considered accurate to better than an order of magnitude.

Now consider the consequences if $N_C = 10^7$. Then $d = 100$ light years, and the number of likely stars within this range is 10^3. The frequency of occurrence, p, of superior communities among likely stars, is 10^{-3}. Although we have no evidence for intelligent life elsewhere, yet if we consider that on the average it takes 5×10^9 years for a likely star to produce one superior community, which then endures for an average life-time Δ measured in years, then $p = 10^{-3}$ implies a Δ of 5×10^6 years, assuming that we are in a state of secular equilibrium. This would seem to offer ample time to explore the 10^3 stars out to 100 light years and establish a chain of communication.

Consider the consequences, however, if technology in our galaxy is less abundant, for example, take $N_C = 10^3$. Then $p = 10^{-7}$, $N_L = 10^7$, $d = 2{,}000$ light years, and $\Delta = 500$ years. The duration of communities which can maintain a frequency of occurrence of only 10^{-7} is thus, on the average, too short to permit interstellar traffic.

If intelligent life does develop on other likely systems at the same tempo as ours has developed, and if some superior community has not made contact with us, it may simply be that the mortality-rate for advanced civilizations is too high for them to become abundant in the Galaxy. Even so, it is rather striking that there would be a thousand superior communities present in the Galaxy at any time even though it takes as long as five thousand million years to produce a technological community that is viable, on the average, for only 500 years beyond the point we have reached.

Even in the event of technology being rare, there is, however, the possibility of a chain existing. Thus, in a Galaxy supporting only 10^3 superior communities with brief expectation of life, there may be some communities that have achieved durability, even quasi-permanence, perhaps by gaining control of the circumstances that lead to short average life-times. Aided by accidental proximity due to random spacing, some of these could be in contact. Presumably such an ancient association would be very able indeed technically, and might seek us out by special means that we cannot guess. Whether they would be interested in rudimentary societies which, in their experience, would usually have burnt themselves out before they could be located and reached, is hard to say. Such communities would be collapsing at the rate of two a year (10^3 in 500 years), and they might already have satisfied their curiosity by archæological inspection made at leisure on sites nearer home. On the other hand, the prospect of catching a technology near its peak might be a strong incentive for them to reach us.

CO-ORDINATION OF LIGHT AND ELECTRON MICROSCOPY

BEING such a complicated and expensive instrument, the electron microscope until recently has remained largely in the hands of physicists. For developing operating techniques, and to a large extent special preparative methods also, this circumstance had distinct advantages, but inevitably it biased the use of the instrument in the direction of high resolving power, of investigating structures and particles (such as viruses) well beyond the limit of the optical microscope. A jump of one hundred times in useful magnification gave some excuse for this attitude, perhaps. There may also have been some tendency to regard electron microscopy as a field of research in its own right, both in biological and metallurgical applications, with the ill-result of detaching it from work done at lower magnifications. Properly seen, of course, it is just another tool of research, albeit a most powerful one, to be used in co-ordination with the established optical and other techniques for investigating microscopical structure. With the gradual realization that it is best situated in the laboratory of the scientist who wants to make use of it—even though it still requires a physicist to bring out all its potentialities—the electron microscope in the past few years has begun to find its way into departments of botany, zoology, metallurgy, and so on. As a result, increasing attention has been given to considering how to correlate its use with other techniques of observation, such as phase-contrast, polarizing and interference microscopy, in addition to X-ray and electron diffraction. It was this trend that prompted the Royal Microscopical Society to approach the Electron Microscope Group of the Institute of Physics, which until now has been responsible for the subject in Britain, to join in organizing a symposium on "The Co-ordination of Light and Electron Microscopy". The meeting was held in the University of Leeds during March 31–April 1. Its timeliness was reflected in an attendance of more than 150, including a number of visitors from Belgium, Holland, Germany and the United States. The proceedings, which will be published in full in the *Journal of the Royal Microscopical Society*, consisted of eight invited papers and a number of short contributions to the discussions on them.

The symposium opened with a detailed review by Dr. R. Barer (Department of Human Anatomy, University of Oxford) of the various methods of microscopy now available. He brought out the range of applicability and the degree to which quantitative information could be obtained with each technique. Prof. I. Manton (Department of Botany, University of Leeds) followed with a talk on the co-ordinated use of electron microscopy and a group of optical techniques in plant cytology, beginning with some remarks on the general difficulties of importing physical methods into a biological laboratory. It is not so much the first cost of an electron microscope as the running costs and the provision of specialist technicians which give trouble. The scale of staffing and expenditure is foreign to the experience of a biologist, and even to a university as a whole, as appeared from later discussion. The best use cannot be made of these new instruments, many of which are bought with grants from trusts and foundations, unless more adequate recurrent funds are made available by universities and the research councils, which ultimately means from government sources. Prof. Manton went on to describe the investigations made in her laboratory into the structure of micro-organisms, and particularly of their cilia. She emphasized the value of light microscopy of specimens dried in a controlled manner, as well as the use of the phase-contrast method for living material. The study of serial sections in the electron microscope may be complemented by through-focal observations in the ultra-violet microscope. Dr. A. D. Greenwood, of the same Department, showed a three-dimensional reproduction of a chloroplast which had been made with the aid of these techniques.

In the afternoon session the use of a selected battery of techniques was further illustrated by Dr. D. Lacy (Department of Zoology, St. Bartholomew's Hospital Medical College, London), on the basis of his own studies of the rat testis, and by Dr. K. M. Rudall (Department of Biomolecular Structure, University of Leeds) in a review of the work done in a number of laboratories on the cross-banding and fine structure of fibres and, in particular, of muscle, nerve, keratin and collagen. Mr. D. H. Page brought a different point of view, in describing the methods developed at the British Paper and Board Research Laboratory, Kenley, for studying the surface of paper and related materials. Ordinary optical techniques are inapplicable, except at low resolution, and transmission electron microscopy is of little help. Much information has been obtained by adapting the shadowcast replica method of electron microscopy to the conditions of optical microscopy. The final replica is embedded in a plastic block, so that the full aperture of the light microscope can be used and high resolution obtained. Much use has also been made of reflexion and scanning electron microscopy, which provide an image with considerable three-dimensional detail at a useful magnification just beyond that of optical methods.

On the following day, a paper by Dr. J. Nutting and Dr. P. Kelly (Department of Metallurgy, University of Cambridge) presented a wide survey of the microscopical techniques used in metallurgy, including X-ray as well as optical and electron methods. The overlapping of their ranges of applicability was displayed by means of a diagram (Fig. 1), in which resolving power is the abscissa and depth of focus the ordinate. Depth of focus is important in metallurgical work, since the relative height of surface features often comes in question. The complementarity of the available methods is well brought out by the diagram. Particular attention was paid to the new techniques developed for observing thin films of metals directly in the electron microscope and to new optical methods for observing slip lines and dislocations. Dr. A. Keller and Mr. D. C. Bassett (H. H. Wills Physics Laboratory, University of

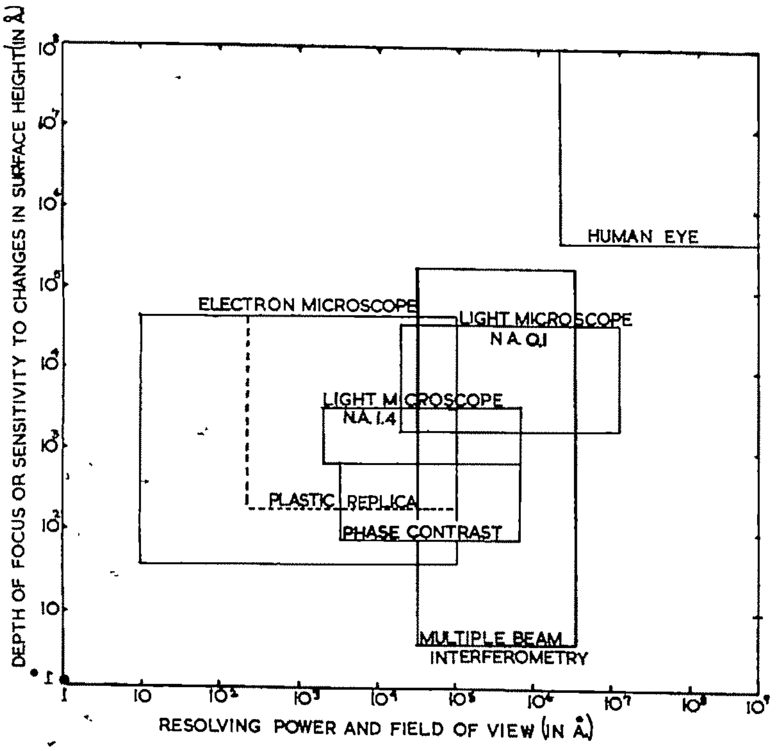

Fig. 1. Range of applicability of a number of microscopic techniques, in terms of resolving power and depth of focus (after Nutting and Kelly)

Bristol) gave a similar review, though on a narrower front, of light and electron microscope investigations of the habit and structure of crystals, particularly of long-chain polymers. Those of polyethylene are so sensitive to the electron beam that progress has only been possible by careful correlation of optical observations with those made by specially developed electron microscopical techniques at low and intermediate magnifications. The final paper, by Dr. Anna Cosslett (Cavendish Laboratory, University of Cambridge), dealt with the use of some of the optical techniques in association with electron microscopy in a few selected problems, and so far as possible quantitatively, rather than with a broad survey of a branch of science. The ultra-violet microscope at its highest resolving power provides semi-quantitative evidence of the distribution of nucleic acid in chromosomes and micro-organisms, for example, for comparison with the various light and dark regions seen in electron micrographs. The interference microscope can be used to measure the changes in thickness and refractive index of thin sections caused by exposure in the electron beam. In this way the competing effects of loss of material by irradiation and deposition of 'contamination' have been followed in a variety of plastics used for embedding purposes. As much as 50 per cent is lost from some, and 20 per cent from the most resistant, even with an electron dose very small relative to that incurred in normal operation of the microscope.

The main features of the contributions and discussions were summed up by Dr. V. E. Cosslett (Cavendish Laboratory, University of Cambridge). The fruitfulness of a combined attack with all the relevant optical and electron microscopical techniques had been demonstrated in every paper. X-ray methods, which had had little mention, could provide a further dimension in so far as they give information about the nature and amount of the different elements locally present in a specimen. For the most part, light and electron techniques give only the distribution of dry mass, although optical microspectrometry of stained specimens can now explore the localization of particular biological compounds. Optical microscopy will continue to be indispensable in electron microscopy for charting a course through the specimen at the higher available magnification and, even more important, for checking the incidence of artefacts in the various stages in its preparation. At the same time, electron microscopy is beginning to feed back ideas to optical microscopy, in new preparative methods and also in demanding that optical techniques be used to the very best advantage. The standards set by the great light microscopists of the end of the past century are now being re-discovered, and more attention is being paid to teaching the use of the light microscope at high resolution.

Great progress has been made with the electron microscope, since it was invented thirty years ago, but a comparison with the range of optical methods now available brings out how much remains to be done. An electron interference microscope, of limited applicability, has been constructed, but a practicable electron phase-contrast system is not yet in sight. Our electron lenses are still extremely primitive, and, although methods of correction are known in principle, there is a long way to go before a lens corrected for operation at even moderate aperture can be built. The wave-length range available for electron microscopy is barely 1·5 as compared with an optical range of 5 or more. Experimental work at accelerating voltages down to 10 kV. and up to 350 kV. has shown the value of variable wave-length, for image contrast on one hand and specimen penetration on the other; but commercial instruments for the upper and lower ranges are only now being projected. The biggest problem remaining to be solved is that of examining living matter in the electron microscope. Some recent work in Germany and the U.S.S.R. has suggested that this may not be absolutely impossible, as had been thought from the few attempts made in the early days of the subject. It may be that a combination of high-voltage operation with indirect observation at low beam current, using an image intensifier, will allow electron images to be obtained of a limited class of organism and at moderate magnification. Even if we can do no more than follow the effect of radiation damage, this would be of great interest if it is at a resolution appreciably better than that of the light microscope. Such an advance is still many years away, even if it be possible at all. If it is made, then the co-ordinated use of optical and electron microscopical methods will be even more vital than it is in present fields of research.

V. E. Cosslett

SCIENTIFIC TECHNIQUES IN ART AND ARCHÆOLOGY*

By DR. A. E. WERNER

Department of Research Laboratory, British Museum, London, W.C.1

IT was in France during the last quarter of the eighteenth century that certain chemists began to apply their specialized knowledge in the field of the fine arts. Their efforts were first directed to the discovery of new artists' pigments. Thus, in 1781, Guyton de Morveau discovered zinc white which he recommended as a new white pigment that would resist the action of sulphurous fumes in urban atmospheres which tended to darken white lead. In his plea to artists to use this pigment, despite the fact that it was more expensive than white lead, he ended his paper to the Academy of Dijon with the phrase: *"On ne marchande pas l'immortalité"*[1]. In 1804 the chemist Chaptal was anxious to find a blue pigment which could be used by the Sèvres porcelain factory in place of the expensive imported ultramarine. He commissioned Thenard to undertake the necessary research, and in a few months he discovered the pigment cobalt blue which now bears his name.

Certain distinguished scientists in Great Britain soon began to follow the example of their colleagues in France. In 1815, Sir Humphry Davy published his classical paper entitled "Some Experiments and Observations on the Colours used in Painting by the Ancients"[2] in which he analysed and identified pigments found at Pompeii, and in 1818 he was commissioned by the Prince Regent to examine manuscripts that had been recovered from Herculaneum in order to find a way of unrolling them without damage[3]. In 1843, Michael Faraday, when lecturing at the Royal Institution, exhibited leather-bound books from the Athenæum Club which were in a very bad state of decay. He correctly attributed this condition to the products of combustion of coal gas and demonstrated that the moisture from a gas flame, condensed on cold metal, contained sulphuric acid. This was the earliest observation concerning the decay of leather by sulphuric acid. In 1853, Faraday served as an expert witness before the Select Committee of the House of Commons which was appointed to inquire into the methods of cleaning paintings being used at the National Gallery at that time.

These examples represent, however, isolated occasions when scientists were called upon to use their specialized knowledge. The intensive application of scientific methods in art and archæology is, on the other hand, of comparatively recent origin.

The work that is carried out in museum laboratories may be considered under three aspects. One is the application of scientific methods to the conservation of works of art and antiquities, the second is the extension of our knowledge about the materials and techniques of painters and craftsmen so as to acquire general information of value to the scholar and art historian, and, thirdly, there is the question of providing objective criteria relating to the authenticity of works of art and antiquities.

Let us consider first of all the use of scientific techniques in the examination of paintings. Normally, one regards a painting from the purely artistic point of view; but, in order to appreciate how scientific methods are employed in the examination of paintings, it is necessary to realize that, from a physical point of view, a painting is a stratified object consisting of four essential layers. These are (starting from the back) the support, the ground, the paint film and the varnish film. In the case of early paintings, the support was usually of wood but, from about the fifteenth century onwards, canvas was used. The ground-layer consisted of a white inert material in a glue medium; in Italy and southern Europe calcined gypsum (hence the word *gesso* often used in describing this layer) was used as the white inert, but in northern Europe it was normally chalk.

Great care was taken by the Old Masters to produce a ground which would have a finished surface that would be as perfect as possible for painting upon; in the words of Cennino Cennini —the famous fifteenth-century writer—it should be "as white as milk (*biancho chome lacte*)" and "smoothed as if it were an ivory (*pulendo si chome fusse uno avorio*)"[4].

The paint film consisted of an aggregate of pigment particles in a binding medium. In so-called tempera painting the medium was egg-yolk, but this was later replaced by various drying oils—the commonest being linseed oil.

The varnish layer was not really an integral part of the painting. It was usually applied after a period of time and served a two-fold purpose; it protected the paint film against atmospheric contamination and restored the original brilliance to those oil paintings which tended to become rather dull in the course of time.

Among the physical techniques used in the investigation of paintings, X-rays are of paramount importance. The degree of absorption of X-rays passing through a painting will depend primarily upon the chemical nature of the pigments present. This can be conveniently expressed in terms of the mass-absorption co-efficient (μ/c), the value of which will be greater for pigments containing elements of high atomic weight. Thus, the value for white lead is about ten times greater than that for calcium pigments such as chalk or gypsum. It is fortunate that calcium pigments were used for the ground-layer whereas white lead was extensively used in the actual paint layers. This means that the ground is relatively transparent to X-rays, whereas the paint layers—particularly those areas containing white lead—will be registered in radiographs. The radiographic examination of paintings is not new; in fact, shortly after Röntgen discovered X-rays in 1895, radiographs were being made of paintings. However, improvements in X-ray equipment and a true understanding of the physical factors involved in the X-ray photography of pictures were necessary before the technique could be used to its full advantage[5].

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on March 11.

Radiography can often yield information about the technique of an artist. Thus, an X-ray photograph of the painting of "S. Catherine of Alexandria" (National Gallery 168) by Raphael shows that the background (a blue sky) is relatively opaque to X-rays whereas the figure of S. Catherine is more or less transparent to X-rays. This means that the luminosity of the background has been achieved by using a paint containing a large amount of white lead, whereas the luminosity of the figure has been created by allowing the ground to serve as a white reflecting layer which shines through the thinly superimposed layers of flesh paint.

Information can also be obtained which may assist the art-historian in determining the attribution of a painting. Thus in the case of a large altar-piece in the National Gallery originally ascribed to Ercole Grandi (National Gallery 1119) doubts were raised about the attribution. When the Madonna's head was examined, the radiograph showed that the superficial image was very thinly painted and was barely visible, whereas underneath, and posed at a different angle, the original version of the Madonna's head showed up clearly and was obviously painted in a different style. This showed that two artists had been engaged on this altar-piece, and documentary evidence confirmed that this painting was started by the artist Maineri, and finished by Lorenzo Costa. What we see to-day is Costa's version of the Madonna's head which was repainted over Maineri's version, which is visible in the radiograph.

Another physical technique used in the examination of paintings is infra-red photography. Infra-red radiation has a greater penetrating power than visible light so that it can pass through the varnish and uppermost paint layers, and, if the underpaint or ground has a high reflectance coefficient around 8000 Å., it is often possible to reveal *pentimenti* (that is, alterations in composition made by the artist himself) not visible to the naked eye. One rather dramatic example of the success which can be achieved occurred in connexion with van Eyck's well-known painting, "The Marriage of Arnolfini" (National Gallery 186). The artist's first sketch of Arnolfini's right hand as drawn in charcoal on the white chalk ground was clearly revealed beside the final painted version of the hand now visually apparent in the picture. The reason why the initial drawing shows up in the infra-red photograph is that carbon absorbs infra-red radiation whereas chalk reflects it.

Differences in the infra-red reflectance of pigments can often yield information about over-painting. Thus, in a picture by a follower of van der Weyden, "The Exhumation of S. Hubert" (National Gallery 783), the bishop's cope appeared to be painted in a uniform dark blue colour. However, an infra-red photograph revealed an overpainting, which appeared almost black. Subsequent chemical examination showed that the paint in this dark area was a mixture of Prussian blue and chrome yellow. These pigments absorb infra-red radiation to a greater extent than the pigment used in the original paint and hence appear dark against the rest of the cope. This overpainting had been carried out to conceal a hand belonging to the figure standing beside the bishop. When an X-ray examination showed that this hand was, in fact, not badly damaged but was in a good state of preservation, this overpainting was removed and the hand once again revealed as it had been originally painted.

Ultra-violet radiation also can be used for the examination of works of art. Retouchings on paintings and repairs in ceramic or bronze objects are revealed because they show a different fluorescence from that of the background, and in the case of drawings which have faded, fluorescence under ultra-violet may render them visible. Thus, in a collection of drawings by Leonardo da Vinci in the Royal Library at Windsor Castle, there were two sheets upon which very little was visible; but under ultra-violet light they became alive with drawings of hands which were identified as sketches for the "Virgin of the Rocks"[6]. These sketches had been done on a pale pink paper using a soft metal (probably silver) pencil as the drawing instrument. In the course of time the traces of metal were either rubbed off or, possibly, converted into a colourless compound so that the drawing disappeared. However, there still remained enough of the metal to give the characteristic fluorescence under ultra-violet light and bring these sketches miraculously back to life.

Physical techniques give information about the structure of a painting, but chemical—or rather micro-chemical—techniques are concerned with the actual nature of the pigments and binding media used. Precise micro-chemical tests for the identification of pigments have been developed using modern organic reagents for metals in conjunction with Feigl's 'spot test' techniques. Details of the method and typical examples of the reagents used in the National Gallery laboratory have been given by Miss R. J. Plesters[7]. As a natural extension of pigment identification the technique of preparing paint cross-sections has been developed. Minute fragments of paint are embedded in a suitable synthetic resin (for example, polymethyl methacrylate or a cold-setting poly-ester) which is ground down on emery papers until the paint fragment is exposed; the layers of paint can then be examined under the microscope, and information be derived about over-painting and about artists' methods[8].

Recently this technique has been advanced a stage further by Dr. P. Coremans[9], who has succeeded in preparing paint cross-sections which are sufficiently thin (20–30μ) to be viewed under the microscope in transmitted light at a high magnification. Such cross-sections permit a much more precise examination of the structure and composition of the various layers of a painting. Thus, in a fragment of blue paint from van Eyck's "The Mystic Lamb", it was possible to recognize no less than eleven layers; of these, six were authentic van Eyck and consisted of a chalk ground, an isolating layer of oil, three layers of opaque paint containing azurite and lead white in an oil medium and a translucent glaze consisting of natural ultramarine in an aqueous medium, whereas the other five consisted of three layers of varnish between which were sandwiched two layers of repaint containing the modern pigments synthetic ultramarine and Prussian blue.

When compared with the precise tests for the detection of pigments, the methods available for the identification of media were less satisfactory, and were largely based on the comparative behaviour of media towards different solvents. However, the technique of partition chromatography has been successfully applied to this problem and methods have now been developed in the National Gallery Laboratory[10] for the precise detection of the presence of resins, oil, egg-yolk and glue in paint media.

When one passes from paintings to a study of archæological material, the problems of scientific examination and conservation are quite different. One has to deal with a wide range of objects which differ in their material make-up and are liable to have undergone profound changes while buried in the ground. Methods for the treatment of waterlogged wood, porous ceramic objects saturated with soluble salts, and corroded bronze objects have been recently discussed in *Nature*[11]. Attention will therefore be focused on a few examples selected to illustrate some general principles involved in the examination and treatment of metallic antiquities.

The first example relates to a silver cup which was excavated at Enkomi in Cyprus and was dated about 1400 B.C. This was covered with green corrosion products derived from the copper present in the alloy which had been leached out while the cup was buried. Preliminary examination showed the presence of gold and a black powdery substance which spectrographic analysis showed to be probably a material called *niello* (a mixture of the sulphides of silver and copper). The detection of gold and *niello* suggested the presence of a decorative inlay, and radiography confirmed that this original decoration still survived under the corrosion products. The problem, therefore, was to remove the incrustation and reveal the ornamentation without losing either the gold or the *niello* in the process. Experiments with *niello* prepared in the laboratory showed that this material was unaffected by hot formic acid. This reagent, therefore, was used to remove the unsightly incrustation and the original decoration was revealed in a surprisingly fresh condition[12].

The next example is instructive because it shows that, in the case of iron objects, material which at first appears most unpromising may yield interesting results. A small fragment of a Roman sword of the second century A.D. appeared to have been reduced to a mass of rust. However, radiography revealed evidence of inlays, and, with the X-ray photograph as a guide, the rust was carefully removed to reveal the inlays which had been done in a yellow alloy of copper and zinc (so-called orichalcum). On one side of the fragment there emerged a figure which was identified as the god Mars, and on the other side the Roman eagle with standards.

The conservation of archæological material often presents problems which necessitate the development of a novel technique. Thus, about two years ago an important archæological find was made on the site of a mediæval church in St. Ninian's Island in the Shetlands. This consisted of twenty-eight metal objects thought to be early Christian in origin and to date from about A.D. 800. These objects were regarded by the excavators as bronze, but examination showed that the metal was, in fact, a base silver alloy containing much copper which had mineralized during the years of burial to form a thick coating of copper corrosion products. The most interesting item in this hoard was a composite object thought to be a hanging bowl with an internal liner. This supposed liner was soon found to be a separate decorated bowl, which had been pushed into the hanging bowl, and it was easily removed and cleaned. The hanging bowl itself was of particular archæological significance, because it is the only known surviving example of a *silver* hanging bowl to have been found in Britain. Its conservation presented a problem of peculiar interest[13]. The strength of the bowl was due almost entirely to the layers of corrosion products, between which egg-shell thin silver was sandwiched; but at the same time it was considered necessary to remove this incrustation because it was unsightly and gave a false impression of the original appearance of the bowl. When cleaned, the hanging bowl was therefore extremely fragile, so that it was necessary to devise some form of internal support to act as a permanent reinforcement. After a series of trial experiments, a cold-setting epoxy resin ('Araldite' casting resin *F*) was chosen because it adheres well to metal, is transparent, and sets without appreciable shrinkage. A viscous mixture of resin and hardener (together with dibutyl phthalate as plasticiser) was brushed uniformly over the inside of the bowl, which was rotated on a small turntable so as to keep the resin mixture uniformly distributed while it set. In this way it was thus possible to reinforce the bowl with a thin transparent film which gave sufficient mechanical strength so that the bowl could be handled with perfect safety.

When scientific methods are used in connexion with the authenticity of antiquities, the evidence obtained may be either positive or negative. In the former case, the evidence will indicate the approximate age or the definite antiquity of the material of which the object is made, thus establishing probable authenticity. In the latter case, one seeks evidence of anachronisms in the use of materials or techniques which prove that the object could not belong to the period assigned to it.

In order to appreciate how varied are the scientific methods that can be used in this field, it is of interest to mention a new technique which was developed at the Leather Industries Department of the University of Leeds to confirm the alleged age of the Dead Sea parchment scrolls. The first step was to take photographs with the electron microscope to show how the actual collagen fibres had undergone a characteristic degradation due to the long sojourn of the scrolls in the dry atmosphere of the caves in which they had been discovered. Then, the decrease in the shrinkage temperature of small fibres teased out from the scrolls was measured, and, by comparing the value found with that of parchments of known date, it was possible to arrive at an approximate age of about two thousand years for the Dead Sea scrolls[14].

In the case of metal objects, a metallographic examination, both of the corrosion products and of the metal remaining beneath the corrosion layers, may provide manifestations of antiquity. It will, however, be impossible to give even an approximate age, because the rate at which a metal corrodes will be greatly influenced by its environment.

Genuine patinas are minerals that have slowly grown on the surface of the metal, and under high magnification they will usually show a complex banded structure and inter-crystalline penetration into the metal leading to replacement of metal crystals by mineral, that is, pseudomorphism. On the other hand, false patinas which are induced by accelerated corrosion can be distinguished by the fact that they tend to be on a much smaller scale, do not usually show the banded structure or penetrate into the metal. A metallographic study of cross-sections of patinas, particularly in the case of bronze objects, may, therefore, yield conclusive evidence either for or against antiquity.

In the case of silver objects, a study of the metal itself may be very informative. Ancient silver acquires a crystalline quality—the characteristic property that accounts for its brittleness. Fractures in the surface of the metal may look lined and decayed like old leather, and granular crystals are often visible.

In contrast to this a technical examination of a silver plate in Bactrian style (second to first century B.C.) revealed features which cast serious doubt on its authenticity. A photomicrograph of dents in the edge of the plate and scratches on the surface showed the silver to be in a ductile condition, and there was no evidence of crystallization. Moreover, when struck, the silver rang like a bell quite unlike the dead response given by highly crystallized silver. Also, the foot rim was in an almost virgin condition and showed no signs of wear; in an object of the presumed age of this plate, which weighed 1,128·5 gm., one would normally expect to find signs of wear visible to the naked eye. In this case none was visible even under the microscope. Another odd feature was the absence of silver chloride—the typical corrosion product of silver to be expected from the presumed environment. These findings were confirmed when the models which served for the design on the plate were traced to a manuscript of the "Fables of Bidpai" in the Yildiz Library at Istanbul[15].

In the scientific examination of paintings of doubtful authenticity one is concerned either with the possible discovery of anachronisms in the use of pigments and media or with abnormalities in technique. Three examples will show how this kind of evidence can be used to detect forgeries. In the case of a painting of a "Laughing Cavalier" attributed to Franz Hals, microchemical examination of fragments of *original* paint revealed the presence of no less than three pigments—synthetic ultramarine, zinc white, and cobalt blue—which were unknown in Franz Hals's time. The presence of these pigments constitutes undoubted proof that this painting could not be by the hand of Franz Hals.

The next example is the famous forgery case which shook the art world on July 12, 1945, when the Dutch artist, van Meegeren, claimed he had painted certain pictures which had been attributed to Vermeer—the most famous of which was the "Christ with the Disciples at Emmaus"[16]. Microchemical tests revealed many facts which clearly showed that these paintings were indeed fakes. Thus, the medium proved to be a modern synthetic phenol–formaldehyde resin, traces of the pigment cobalt blue were found in samples of blue paint, and the dirt in the craquelure—that network of fine cracks which is to be seen on all old paintings—proved to be ordinary indian ink which, moreover, had in places seeped into the porous medium, thus blurring the sharp outline of the cracks, and giving them a very suspicious appearance.

It is also possible to use radiography to unearth further scientific evidence. Since potential buyers of Old Master paintings are always impressed by signs of age in the support, it is a common practice among fakers to use authentic old supports upon which to perpetrate their forgeries. In this particular case, van Meegeren bought seventeenth-century paintings by minor Dutch artists and scraped off as much as he could of the paint so that he had a suitable canvas upon which he could proceed to paint his pseudo-Vermeer pictures.

It is, however, very difficult to remove completely all traces of the original painting, and therefore, when X-ray photographs of these suspected paintings were taken, it was possible in all cases to detect traces of some different painting lying beneath the superficial image. In the case of one of these pseudo-Vermeers representing "The Last Supper", the radiograph showed the distinct outline of dogs and birds. A Dutch art dealer had fortunately kept a photograph of a painting of "A Hunting Scene" by Hondius which van Meegeren had bought from him in 1938. When this photograph was compared with the above radiograph, there could be no doubt whatever that the pseudo-Vermeer "The Last Supper" had been painted over what had once been the Hondius "Hunting Scene".

The techniques mentioned so far can only be applied to detecting forgeries of Old Master paintings. When the question arises of detecting a forgery by a modern artist, anachronisms in the actual materials will obviously not apply. It is necessary instead to obtain evidence about the actual technique of the artist so that it may be compared with the technique of the suspected painting. This can often be achieved by radiography. It was successfully used to unmask a number of van Gogh forgeries which came to light in 1928. When X-ray photographs were taken of these paintings, a striking difference was found between the radiographs of the suspected paintings and the radiographs of genuine van Gogh paintings. The latter showed the powerful brush strokes which give van Gogh paintings their rhythm and true meaning. On the other hand, the radiographs of the forgeries showed the restless nervous brush strokes of the faker, who had merely succeeded in imitating the characteristic superficial appearance of van Gogh paintings.

This account of the kind of work carried out in a scientific department attached to a museum or art gallery will show that the work is very varied, both as regards the type of problems—whether of conservation or scientific examination—and the methods which are brought into play to solve them. The scientist is often accused of indulging his idle curiosity, and at first his intrusion into the museum and art gallery may perhaps have been viewed by the scholar with a certain amount of alarm. However, the position has now happily arisen in which there is active and intimate co-operation between the scientist and the scholar in the study of problems of mutual interest. In this field it can be justly claimed that a successful attempt has been made to bridge the gap which has sometimes been presumed to separate science and art.

OBITUARIES

Prof. E. G. Richardson

EDWARD GICK RICHARDSON, who died on March 31 at the age of sixty-three, was well known, not only in Great Britain, but also internationally, for his work in acoustics and ultrasonics.

He took the degree course in physics at East London (now Queen Mary) College, graduating during the First World War. He then served in the Royal Air Force (Balloon Section), which no doubt initiated his life-long interest in aerodynamics and meteorology. After a short period as a grammar school master, he undertook research at East London College under Prof. C. H. Lees. About two years later he was appointed a lecturer at University College, London, and during the next seven years his research work in acoustics, recognized by the award of a D.Sc., firmly laid the foundation of his subsequent reputation. In 1931 he moved to King's College, Newcastle upon Tyne, where he spent the rest of his life; he was made a reader in 1943, and in 1956 a chair in acoustics was created for him.

Richardson's research achievement was so extensive and diverse that no brief summary is possible. It must suffice to say that he published some ninety papers on a wide variety of topics, including, besides acoustics and ultrasonics, liquid jets and suspensions, viscosity, hot-wire anemometry and viscometry, atmospheric turbulence, relaxation processes and fish locomotion. In acoustics he made notable contributions to many branches; among these the best-known are probably the absorption of sound in vapours and narrow tubes, phonetics and speech analysis, and æolian, edge and transient tones. In later years he turned his attention to ultrasonics, with special reference to absorption and dispersion. In these researches he was often assisted by students, many of them from overseas, who owe much to his help and encouragement. His experimental work was characterized by directness of attack and economy of means, and he was particularly interested in new lines of investigation. He opened up many of these, leaving others to explore the territory which his work had made accessible.

In addition to his research work, Richardson found time to write upwards of a dozen books, including several compilations which he edited or to which he contributed sections. The most widely known are probably "Sound" (a very popular textbook), "The Acoustics of Orchestral Instruments", "Acoustics for Architects" and "Physical Science in Art and Industry". He wrote fluently and well, with an admirable clarity of expression and an easy mastery of his subject. He was English editor of the international journal *Acustica*, in the founding of which he played a prominent part.

He received numerous invitations to lecture abroad, and did so in the United States (several times), Canada, India and most countries of Europe. He was visiting professor of physics at the University of Cairo for a term in 1947, and a Leverhulme Fellow during 1955–57. During the Second World War he served as scientific adviser from early 1940, first in the Admiralty (Mine Design Department) and later in the Air Ministry (Royal Aircraft Establishment and Helensburgh). After returning to King's College he carried out various research contracts for these Ministries.

Although Richardson's primary interest was research it was by no means his only one, for he was an accomplished musician, a dedicated cyclist, and an indefatigable member of the College Country Dancing Club. He played both piano and organ well, and for many years travelled between Durham and Newcastle twice daily on Sundays (some sixty miles in all) in order to sing in the Cathedral choir. He was a deeply religious man, although none but his closest friends would be aware of this, for he was somewhat shy and reticent by nature. Nevertheless, his sterling qualities of modesty, sincerity and kindliness were apparent to all who knew him, and endeared him the more the better one knew him. His sudden death was a great shock to all his friends; they will long bear him in affectionate memory.

W. E. CURTIS

Dr. John Duckworth

THE sudden death on April 11 of Dr. John Duckworth, head of the Applied Biochemistry Department of the Rowett Research Institute, Aberdeen, has robbed the science of food and agriculture of an outstanding investigator.

Born in Manchester but educated in Canada, and in the course of his life conducting research in Canada, Trinidad and Guatemala, he spent about a quarter of a century in the service of the Rowett Institute at Aberdeen. He obtained his original training at the Ontario Agricultural College, Guelph, and took the degree of B.S.A. at the University of Toronto. He next spent a year with Lever Brothers, Ltd., in Toronto, as analytical chemist, and another year with the same firm's economics section studying production efficiency. In 1931 he became assistant to the professor of chemistry at Macdonald College, McGill University, where he carried out research on the blood chemistry of cattle afflicted with genital disease, and on contagious abortion in cattle.

In 1933, Dr. Duckworth came to the Rowett Institute, where he investigated the relationship of nutrition to pathological conditions in farm animals. He also worked on the partition of serum calcium and the factors affecting it. The object was to establish a closer relationship between the blood picture and the evidence of certain types of disease, such as milk fever and rickets, in farm stock. The latter work was incorporated into a thesis, for which the University of Aberdeen awarded him the degree of D.Sc.

Later he investigated magnesium metabolism in animals, and the influence of fibre in the diet on the utilization of protein and calcium. He collaborated in work on problems connected with both human and animal nutrition, for example, the utilization of phytic acid phosphorus in oatmeal by men and farm animals.

In April 1944 he was appointed senior lecturer in the Agricultural Department of the Imperial College of Tropical Agriculture, Trinidad. There he developed courses of instruction in animal husbandry, and created a nutrition laboratory for investigation of the value of various feeding stuffs under tropical conditions.

In September 1946 he returned to the Rowett Institute, and three years later became head of the Department of Applied Biochemistry. His work concerned protein and vitamin requirements, energy needs and metabolism, and mineral metabolism and requirements. He also developed chemical tests which might be correlated with the biological value of proteins. With Mr. N. W. Pirie, of Rothamsted Experimental Station, biological tests had been made on leaf protein for non-ruminants.

Duckworth was responsible, with the Institute's X-ray Section, for developing a mobile X-ray unit for the outdoor study of hill sheep in relation to calcium and phosphorus requirements. In his Department the role of copper in the ruminant was also under investigation, and much progress was being made in the elucidation of this problem.

In 1954, Dr. Duckworth was elected a Fellow of the Royal Society of Edinburgh, and in 1955 was one of four British scientists who attended a symposium of Europe's leading agricultural research experts in Rome, sponsored by the Pfizer Agricultural Research Institute of America, for discussion of research into the use of antibiotics and other new growth factors in animal nutrition. Later in the same year, he was one of three British experts invited to an international conference in Washington on the same subject.

From August 1956 until August 1957, he was seconded to the Food and Agriculture Organization of the United Nations and the United Nations Children's Fund, to assist the Governments of Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua and Panama on food and nutrition policy. With Señorita E. Musmanno of Argentina, he collected statistics of the countries' food production, which showed that between 6 and 10 per cent of their population were dependent on outside sources of food supply. If one took into account the rate of growth of the population, it appeared to be necessary to double food production in the next twenty-five years, and to alter the balance between cereal and livestock production in favour of the latter. Due account was taken of the actual situation in the area: for example, cattle and sheep raising was to be based on native stock feeding on grass, rather than on imported stock eating concentrate feeding stuffs, at least in the early stages. The need was stressed for modern factories for milk and meat products. Almost his last task was to check the Spanish edition of their second report on the area.

Dr. Duckworth was an enterprising yet meticulous experimenter, a skilled statistician and planner, an arresting and clear expositor of his researches, and one who knew the agricultural industry as few others. He was a lively conversationalist and good pianist. He is survived by his wife, and a son and daughter.

D. P. Cuthbertson

Prof. K. W. Szarski

The death of Prof. Kasmierz Witalis Szarski on January 18 prematurely severed a life of great service to zoology and Polish universities. He was born in Vienna in 1904 and on the family's removal to Lwów attended school and the University there. He took his doctorate, and seven years later (1939) became *docent* in comparative anatomy. Soon afterwards the Russians occupied the University and demoted the staff. Later, under Nazism, academic work ceased, but by acting as hosts for lice used in preparing Prof. Weigl's anti-typhus vaccine, Szarski and colleagues slightly eased impoverishment and received certification as persons usefully employed. Afterwards he and his wife were arrested in Warsaw, but by mere chance escaped transportation to Nazi concentration camps and secured release, he being directed to vitamin investigations.

When war ended, Szarski became professor of comparative anatomy at Wrocław, the new setting for the University of Lwów—Polish no longer. Amid the devastation of Wrocław half the zoological institute lay ruined and in its and the University's rehabilitation Szarski played a leading part, particularly as pro-rector and rector (1954–59).

Szarski was a born naturalist. His early researches related principally to developmental anatomy: three long papers on the urogenital systems of mice being authoritative. His post-war work mainly comprised ornithology and translation. His account of the birds adopting residential niches in the mountainous ruins of Wrocław is fascinating. Freed from rectorial labours, he turned eagerly to study the avian brain—promising work cut short by his death. His comprehensive learning in zoology and his command of Slav and European languages—especially English, French and German, fitted him perfectly as counsellor, editor and translator in many professional capacities. His notable translations, with scholarly commentaries, comprise Darwin's "Voyage of the Beagle" (two editions) and Darwin's and Wallace's historic essays on natural selection (Linnaean Society of London). He was deservedly honoured when chosen to deliver the Darwin Centenary Lecture to the 1959 Polish Zoological Congress in Cracow—practically his last service to science.

Szarski was small and delicate-looking; of great culture, wit, sensitivity and charm; unpretentious; of highest integrity, with an over-riding sense of duty that over-taxed his strength. He had courage: during the Warsaw rising a young insurgent refugee to Szarski's lodging owed his life to Szarski's bluffing of a *Luftwaffe* search-party. He won friendship everywhere: his students and colleagues speak of him as truly 'nieodzalowany' (never to be sufficiently mourned).

Two recent working visits to England gave Szarski renewed inspiration; in Poland British zoologists have profited by his collaboration and enjoyed the bright hospitality of Pani Szarski, himself, and their young daughter, in their modest flat high above the Oder.

In preparing this notice I am indebted to Mr. W. Rybotychi of London, Prof. Sembrat of Wrocław and Prof. Henryk Szarski, rector of the University of Torun.

A. D. Peacock

Prof. Ramesh Chandra Ray

Ramesh Chandra Ray was born in 1890 and took the degree of M.Sc. from the Presidency College, Calcutta, in 1911. He was one of the first students of the Indian Institute of Science, Bangalore, where he worked with Travers on boron compounds formed by the decomposition of magnesium boride. In 1915 he was appointed professor of chemistry at Patna College and, after the War, joined Donnan's laboratory at University College, London, where he continued his work on boron compounds. He succeeded in preparing borohydrates and in establishing the existence of hitherto unknown oxides of boron. For his work on this complicated system he was awarded the D.Sc. of the University of London. He also obtained the fellowship of the Royal Institute of Chemistry.

Returning to Patna, he was responsible for creating a school of research which produced a steady output of papers on inorganic chemistry. The majority of these dealt with boron compounds and formed a valuable contribution to the chemistry of that element. In 1940 he was appointed head of the Department of Chemistry, and in all he worked for thirty-five years at the College. His outside interests were extensive, even after retirement; he was chemical adviser to the Government of Bihar, chairman of the examination board of Bihar University, founder-rector of the Ram Mohun Roy Institute and president of the Manorma Vidyapith. In 1944 he was elected president of the Chemistry Section of the Indian Science Congress.

He died on December 3 and leaves a widow, four sons and three daughters.

NEWS and VIEWS

Electrical Engineering at Cambridge: Prof. E. B. Moullin

PROF. E. B. MOULLIN retires from the chair of electrical engineering at Cambridge on September 30. Thus will end his official connexion with the Engineering Laboratory, which he first entered in 1913. In that year he began to read for the Mechanical Sciences Tripos, having previously taken Part I of the Mathematical Tripos. After a short period in industry, Moullin returned to a lectureship in engineering at Cambridge which he held until 1929. It was during this period that he developed the valve voltmeter associated with his name, and carried out numerous researches in collaboration with L. B. Turner. In 1930 he migrated to Oxford where he held the Donald Pollock readership in engineering science until 1945. Here, his scientific approach to electrical engineering problems attracted numerous research students, several of whom have since achieved world-wide recognition. Moullin was elected to a fellowship at Magdalen in 1932. During the Second World War he worked first at the Admiralty Signals Establishment and later in the research laboratories of Metropolitan-Vickers. In 1945 he returned to Cambridge as the first occupant of the newly created chair of electrical engineering and was elected to a fellowship at King's College. For many years Moullin has taken an active part in the affairs of the Institution of Electrical Engineers. He was chairman of the Radio Section in 1939 and president of the Institution in 1949. He is the author of a number of successful text-books which are distinguished by a freshness and individuality of outlook. His scientific writings cover a wide range of subjects but are largely concerned with problems in electromagnetic theory. The honorary degree of LL.D. was conferred on him by the University of Glasgow in 1958.

Prof. C. W. Oatley

C. W. OATLEY, who succeeds Prof. Moullin in the chair of Electrical Engineering at Cambridge on October 1, was educated at Bedford Modern School and St. John's College, Cambridge. He read both parts of the Natural Sciences Tripos, specializing in physics, and graduated in 1925. After a short spell in the radio-valve industry he was appointed to a demonstratorship in the Physics Department of King's College, London, where he worked under Sir Edward Appleton and later under Sir Charles Ellis, until the outbreak of war. During this period his interests were centred on various problems of electron physics, particularly those concerned with the measurement and interpretation of the contact potential difference between metals. In 1939, Oatley joined the Air Defence Experimental Establishment of the Ministry of Supply, then situated at Christchurch. There he took charge of a group working on radar receivers and became especially interested in ultra-high frequency and microwave measurements. In 1942, when the Establishment moved to Malvern and became the Radar Research and Development Establishment, Oatley was responsible for all basic research work. A year later he became deputy to the Chief Superintendent and, during 1944–45, was in charge of all technical work in the Establishment. In 1945 he returned to Cambridge with a lectureship in the Department of Engineering and a fellowship at Trinity College. During the past fifteen years he has been active in building up research work in electronics and has become interested in problems of electron microscopy. He was appointed to a readership in 1954. Since the War he has had close connexion with the work of the Institution of Electrical Engineers. He served on the Radio Section Committee for a number of years and was chairman of the Section in 1954.

Chemistry at Aberystwyth: Prof. C. W. Davies

PROF. C. W. DAVIES, who is retiring from the chair of chemistry in the University College of Wales, Aberystwyth, is well known for his many contributions to electrochemistry extending over an active research career of more than thirty years. Prof. Davies early became interested in the conductivity of electrolytes, and at the appearance of the Debye–Hückel theory he was among the first to suggest the combination of the law of mass action with the ionic interaction theory to account for the conductivity of strong electrolytes. He showed that the dependence on concentration of the conductivity of many electrolytes could be accounted for if they were incompletely dissociated in solution. This conclusion was not at first readily accepted, because to many chemists the Debye–Huckel theory implied complete dissociation of all electrolytes. The idea that salts are completely dissociated in solution, and that variations in conductivity are due to variations in mobility, was too simple and attractive to be readily abandoned. This difficulty of acceptance was increased by the fact that the physical interpretation of incomplete dissociation was rather obscure. However, Prof. Davies and his collaborators showed that measurements of conductivity and of solubility led to results for dissociation constants of salts in good agreement with one another. Kinetic studies, too, have given results which can only be explained by incomplete dissociation. Apart from the important idea of incomplete dissociation and its careful experimental support, Prof. Davies's other main contribution to electrochemistry was his book, "The Conductivity of Solutions", published in 1929 and in 1933. His more recent work in the field includes studies of the polyphosphate ions in solution, as examples of ions with high negative charges, and the use of ion-exchange resins in electrochemistry. In addition to his personal researches, he has played a major part in building up the Chemistry Department at Aberystwyth to achieve its present reputation as an active centre in physical chemistry.

Prof. A. F. Trotman-Dickenson

Dr. A. F. Trotman-Dickenson, who has been appointed to succeed Prof. Davies, is at present lecturer in chemistry in the University of Edinburgh. In the course of a research career of more than ten years, he has made several important contributions to chemical kinetics, chiefly to the study of elementary reactions in gases. His work with Dr. E. W. R. Steacie at the National Research Council in Canada on the reactions of methyl radicals gave information about the rates with which these radicals abstract hydrogen from a wide range of compounds. Dr. Trotman-Dickenson has studied the abstraction, decomposition and disproportionation reactions of many alkyl radicals and has obtained an important body of new information. In collaboration with Dr. J. H. Knox, he has developed competitive methods for obtaining relative rates of reaction of halogen atoms with various alkanes and has extended such methods to the study of oxidation. He has made contributions to the study of the reactions of the methylene radical. In yet another recent series of experiments, Dr. Trotman-Dickenson has determined several carbon–metal bond-strengths by kinetic methods. In addition to his main work on elementary reactions, Dr. Trotman-Dickenson, along with Drs. H. O. Pritchard and R. G. Sowden at Manchester, has made a most important detailed investigation of the effect of added gases on the rate of isomerization of *cyclo*propane; this gave valuable information about energy transfer to reacting molecules. His book, "Gas Kinetics", published in 1954, is a useful survey of this branch of chemistry, and his recent monograph, "Free Radicals", is a valuable introductory text.

Agricultural Sciences in the Rockefeller Foundation: Dr. A. H. Moseman

Dr. Albert H. Moseman has been appointed director for the agricultural sciences in the Rockefeller Foundation. Dr. Moseman went to the Rockefeller Foundation in 1956 as associate director for the agricultural sciences. Previously he was director of crops research of the Agricultural Research Service of the U.S. Department of Agriculture. He was born in Oakland, Nebraska, received the B.S. and M.S. degrees from the University of Nebraska and the Ph.D. degree in plant breeding and genetics from the University of Minnesota. He served on the mission which helped plan the Point IV programme in agriculture, and was a member of the joint Indo-American team which developed recommendations to the Government of India for improvements in agricultural research and education. The University of Minnesota conferred its Outstanding Achievement Award on Dr. Moseman in 1958.

Biology at Oregon: Prof. G. Streisinger

Dr. George Streisinger has been appointed associate professor of biology in the Institute of Molecular Biology at the University of Oregon as from September 1. Prof. Streisinger is at present at the Carnegie Institution of Washington, Department of Genetics, Cold Spring Harbor, New York. He took his Ph.D. degree in bacteriology at the University of Illinois, and was a post-doctoral fellow of the National Foundation for Infantile Paralysis at the California Institute of Technology. He spent the year 1957–58 working with Dr. Francis Crick in the Cavendish Laboratory, Cambridge. Dr. Streisinger's principal research interest at present is in the relationship between the structure of a protein (bacteriophage lysozyme) and the structure of the gene which controls its formation.

Experimental Biology at Rehovoth, Israel: Prof. J. Berenblum

The establishment of the Jack Cotton research professorship of experimental biology at the Weizmann Institute of Science, Rehovoth, Israel, will help to consolidate and further the work carried out in the Department of Experimental Biology at the Institute. The first holder of the chair will be Prof. I. Berenblum, who has been in charge of the Department since its inception in 1950. This Department comprises a number of sections in different branches of biology and experimental medicine, several of them connected with cancer research—the field of Prof. Berenblum's own specialization. Prof. Berenblum is a graduate of the University of Leeds, a former Beit Memorial Research Fellow (at the Dunn School of Pathology, University of Oxford), and at one time in charge of the Oxford University Research Centre of the British Empire Cancer Campaign. His field of research has been mainly concerned with the 'two-stage mechanism' of carcinogenesis. The proposed expanded programme of research, aided by the munificent gift of Mr. Jack Cotton, will entail the expansion of the work on the two-stage mechanism of carcinogenesis, with particular emphasis on the biological and biochemical role of urethane in the two-stage process, and the extension of the principle to systems other than the skin, including its recently discovered role in leukæmogenesis. The recent addition of further animal buildings, X-ray equipment, and the intended expansion of its biochemical facilities, will further the projected expansion of the research programme.

Amalgamation of the Institute of Physics and the Physical Society

The Institute of Physics and the Physical Society have amalgamated and the new body will be known as "The Institute of Physics and the Physical Society". The first president of the amalgamated body is Sir John Cockcroft, and the four vice-presidents are Dr. J. Topping, Dr. W. H. Taylor, Prof. R. W. Ditchburn and Mr. A. J. Philpot, each responsible to the Council for a defined area of the many activities to be taken over by the new organization from its predecessors. The presidents of the original bodies, Sir George Thomson and Mr. J. A. Ratcliffe, are also members of the new Council. The other officers are Dr. J. Taylor (honorary treasurer) and Dr. C. G. Wynne (honorary secretary).

The Physical Society of London, as it was then called, was founded in 1874, and on the initiative of that Society's Council, the Institute of Physics was founded forty-five years later. The original scheme envisaged a kind of federation of societies interested in physics, to provide, among other objects, rooms for meetings, a library, and a common secretariat. In fact, the Institute's offices were in the Society's present rooms in South Kensington during 1927–49, and the Institute provided the secretariat for the Physical Society and the Optical Society, which themselves amalgamated in 1931. Broadly speaking, before the War the scientific meetings and publications of the Institute were confined to applied physics, while those of the Society were concerned more with pure physics. As, however, the boundary between these two aspects became less definite there has been increasing overlap in the activities of the two bodies and in their membership. It is not, therefore, surprising that during the past twenty years proposals for the amalgamation of the two bodies have been made repeatedly, and from time to time detailed proposals examined, until eventually a satisfactory solution was worked out. The executive officers of the new body are: *Secretary*, Dr. H. R. Lang; *Editor and Deputy Secretary*, Dr. A. C. Stickland; *Deputy Secretary*, Mr. N. Clarke. The registered offices and headquarters are at 47 Belgrave Square, London, S.W.1, and for the present, offices will also be retained at 1 Lowther Gardens, South Kensington, London, S.W.7.

University of Toronto Computation Centre

The Board of Governors of the University of Toronto has approved the proposal to construct, install and operate a copy of *Illiac II* as the major computing facility in the Computation Centre at the University of Toronto. This project is financed in part by a grant of 600,000 dollars from the National Research Council of Canada and the Sir Frederick Banting Fund. *Illiac II* is the high-speed computing machine now being constructed at the Digital Computing Laboratory of the University of Illinois. In it, solid-state devices are used as the main electronic parts. It is designed to be a very reliable and easily serviced machine. Its logical design is elaborate, novel and very efficient in large calculations. The construction at Toronto will be under the supervision of Profs. R. W. McKay and C. C. Gotlieb, who have been associated with the work at Illinois for the past four years. The University of Toronto plans provide special accommodation for the Centre in the new Physics Building to be occupied, it is hoped, in 1962.

Appointments in Industry and Commerce

The annual report for 1959 of the Committee for Appointments, published in a supplement to the *Oxford University Gazette* of March 14, records that of 8,792 vacancies, 5,545 called for men with scientific qualifications, an increase of 2 per cent on the previous year, compared with 11·6 per cent increase in the demand for arts men for industry and commerce. Discussing the effect on graduate employment of the bulge in school population and of the trend to stay on in sixth forms of grammar and public schools, the report stresses the need to convince industrial firms that universities really are creaming off the best of the sixth-form leavers even when university places cannot keep pace with the rise in numbers of sixth formers who are up to normal entrance standards and when sandwich courses are very attractive to parents. Meanwhile, it is apparent that there are far too many mediocre graduates on the market, and three-quarters of the engineering graduates entering the engineering industry make competent specialized technical men but are not up to leading teams in difficult times. The emphasis in recruitment must be on good engineers who can handle people, practical men who can get results from engineering ideas, and the Committee suggests that if the universities cannot prove that such are their products, industry could lose much of its interest in graduates. It is also suggested that there may be a tendency in some firms to concentrate, up to 1965, on school-leavers to the exclusion or partial exclusion of graduates. The school-leaver is refreshingly attractive, being eager to get going in a job, lively, enthusiastic, not choosy, and in contrast with graduates who have been generally cosseted in choosiness and superficial indifference and an attitude suspiciously near that of "the world owes me a living". Pointing out that if the effect of the bulge and trend ultimately is to compel graduates to try harder to secure an appropriate job, graduates will benefit, and commenting on "the dreary procession of would-be B.Sc.'s" seen each year by industrial recruiters, the report suggests that sixth formers may constitute formidable competition in that they will have had two or three years experience.

Choosing a Career

To help young people in their choice of a career, some twelve years ago the Central Youth Employment Executive of the Ministry of Labour and National Service began a series of publications designed to give information about various occupations and the opportunities they provide entitled "Choice of Careers". The series has been remarkably successful and, altogether, 163 editions, many of them revisions of earlier issues, have been published. Total sales of all editions have been well over a million. To mark the issue of the 100th booklet, which is called "The Scientist", the Central Youth Employment Executive has reprinted the first booklet, "Choosing your Career", which deals with the fundamental questions which young people need to pose before selecting a particular occupation in which they intend to pursue a career (Choice of Careers Series No. 1. Pp. 32. 1*s*. 6*d*. net). Another booklet, "Laboratory Technicians and Assistants", is even more profusely illustrated and contains much information about an assistant's job in the laboratory (Choice of Careers Series No. 94. Pp. 56. 2*s*. 6*d*. net). It is surprising, therefore, that "The Scientist" should be produced with such little imagination and launched at half the cost of "Laboratory Technicians and Assistants" (Choice of Careers Series No. 100. Pp. 48. 1*s*. 3*d*. net). The text seems designed to show that the scientist's highest ambition should be to become a 'backroom boy' while, if he turns to industry, he may find jobs in plant management provided he is prepared to give 'technical guidance' in running the plant and not wish to accept "direct responsibility for production management". Little reference is made to the scientific training which our future administrators will need. The tone of the booklet appears to indicate that Whitehall is still controlled by men who believe that men of science can perform useful supporting roles as technical experts, but that direction should rest with men trained in the liberal arts. Forthcoming booklets in the series are to be "Mathematics" and "Applied Science and Technology". The booklets are obtainable from H.M. Stationery Office.

British Water Research Association

THE fourth annual report of the Water Research Association covers the year ended June 30, 1959, and includes the reports of the Council and of the director of research, Dr. R. G. Allen, together with lists of staff and of members (pp. 31+4 plates. Redhill: Water Research Association, 1959). The Association's application for a grant from the Department of Scientific and Industrial Research was approved in February for the five years commencing 1959, at £15,000 a year, conditional on a minimum of £30,000 being raised by the industry, with up to a further £12,000 a year on the basis of £80 for every further £100 of membership income. In his report, the director again refers to the studies of the effect of pH on the coagulation of dilute colloidal dispersions of clay minerals, which have indicated that except for the bentonites, which can be coagulated with low doses of aluminium sulphate at all pH values below 7·5, the amount of aluminium sulphate required to effect coagulation is at a minimum about pH 6·8–7·5. Work on the isolation of suspended colloidal matter in rivers using a continuously operated centrifuge is virtually complete, and a comprehensive investigation has been commenced on the effect of various factors in the preparation of activated silica. Other work has included the effect of physical variants on coagulation, the absorptiometric determination of aluminium, the leaching of lead stabilizers from polyvinyl chloride pipes and the determination of the permeability of plastic pipes to coal gas.

Museum of Applied Arts and Sciences, Sydney

IN common with most museums and art galleries the institution at Sydney is greatly in need of additional buildings to enable the Trustees to fulfil their obligations to the public. Lack of amenities for both visitors and staff, as well as inadequate facilities for exhibition, storage and preparatory work, was causing concern, and disappointment was expressed at the delay in implementing plans for improvement. Recently, however, some progress has been made and plans have been prepared for an extension to the present building and negotiations have started to take over an existing building on a neighbouring site for the storage and display of heavy machinery and transport exhibits. It is the aim of this Museum to show the latest trends in technology and thus provide inspiration and ideals for local manufacturers and others interested. To do so the staff must study developments in science at world research centres and by continuous contact endeavour to obtain specimens and relevant information regarding examples of applied science (Annual Report of the Trustees of the Museum of Applied Arts and Sciences, Sydney, for the year ended 31st December, 1958. Pp. 19. Sydney: Museum of Applied Arts and Sciences, 1960).

New Mineralogical Periodicals

THE formation last year of the Mineralogical Society of India has been quickly followed by the publication of *The Indian Mineralogist*, to be issued by the Society half-yearly as a medium for articles on crystallography, mineralogy, petrology, and allied subjects (Editorial Office: Department of Geology, A.C. College, Madras 25; price 10 R. per annum). The first number (Part 1, 1960) comprises twelve articles in 107 pages, most by Indian workers but a few contributed by Scandinavian and Australian mineralogists. If the initial standard is maintained, the journal will become one of international reputation and the Society should readily enlarge its present membership of 160, mainly resident in Southern India. Simultaneously, a new Russian journal has been issued by the East Siberian Division of the All-Union Mineralogical Society (*Zapiski Vostochno-Sibirskogo Otdeleniya Vsesoyuznogo Mineralogicheskogo Obshchestva*, Academy of Sciences, Moscow: Vol. 1, No. 1, 1959. Pp. 130. price 7r. 30k.), concerned principally with the topographical mineralogy of the territories east of the Urals. The eastward drift of Soviet geological–mineralogical interests is reflected also in the establishment this year of a new Geochemical Institute and Laboratory for Isotope Geology in the town of Irkutsk, administered by the Siberian Division of the Academy of Sciences, and one can expect that there will be no shortage of important contributions to the new periodical.

Compilation of Russian Journals

UNDER the title "Russian Journals", a union list of titles of 54 such periodicals held by four libraries in Manchester and Salford has been compiled for the benefit of scientists, research workers, students and librarians (pp. 14. Library Association: North Western Group. Reference, Special and Information Section. Manchester: Central Library, 1960). In an introduction, Mr. L. L. Ardern, under whose direction the list has been compiled, indicates that the Secretary of the Group will be glad to have details of other Russian titles held by other libraries in the area and to add these to a union list on cards held by the Regional Library Bureau. The entries are listed in alphabetical order of the Russian title, under the society's name if the periodical is published by a society. There is a full index under transliterated and translated titles. The participating libraries are those of the Manchester College of Science and Technology, University of Manchester, Royal Technical College, Salford, and Manchester Public Libraries.

Chromosome Abnormalities in Man

IN a recent issue of *Science Progress* (48, No. 190, April 1960) Dr. C. O. Carter points out that the year 1959 will be remembered for an important breakthrough in the science of human genetics. This was the discovery that certain congenital abnormalities in man are due not to 'point mutations', that is mutations involving only a tiny fragment of a chromosome, but to the addition or loss of whole chromosomes. Most mutations in animals and plants are 'point' mutations, and no change is apparent on examining chromosomes. Some mutations, however, are accompanied by visible changes in the chromosome. These vary from the addition or loss of whole chromosomes to the addition or loss of a small fraction of a chromosome. Investigation has shown that loss of an appreciable fragment, say, a fifth, of an average-sized chromosome is not compatible with life. The presence of extra fragments of chromosome, however, is better tolerated, though resulting in some degree of abnormal development, and in plants a number of examples of individuals with one extra chromosome have been studied. These 'trisomics' have the chromosome number $2n + 1$, and one chromosome is present in triplicate, not paired.

Resistance to Root-knot Nematodes

THE immunity or resistance which some plants possess to attack by root-knot eelworms (*Meloidogyne* spp.) has led to the suggestion that the use of such plants in the rotation, or as trap crops, would effect a measure of control in root-knot infected land. A list of published records of plants showing complete or partial resistance to identified *Meloidogyne* species has recently been compiled and catalogued by Mary T. Franklin and D. J. Hooper on behalf of the Commonwealth Agricultural Bureaux (Plants Recorded as Resistant to Root-Knot Nematodes (*Meloidogyne* spp.). Pp. iii+33. Farnham Royal: Commonwealth Agricultural Bureaux, 1959. 7*s.* 6*d.*). In the first section the resistant plants are listed alphabetically, with the authorities for their scientific names as given in *Index Kewensis* and the breeding line, strain or varietal name if stated, followed by the species of *Meloidogyne* to which they are resistant, with the author and date of record. In the second section the plant species are arranged in their families and listed under each nematode to which they have been recorded as resistant. The third section gives the literature from which the records have been taken. It is emphasized that the plants listed are not necessarily representative of the whole plant kingdom. They are either crop plants in which resistance has been noticed by chance, plants that have been tested for resistance because they would be suitable rotation or cover-crops in root-knot infested areas, weeds growing among infested crops or plants bred for root-knot resistance. For the purpose of the compilation resistance is taken to be any relationship between plant and nematode in which the nematode fails to produce viable eggs. Records of partial resistance (defined as the condition in which the rate of reproduction of the nematode is extremely low in relation to the degree of soil infestation) have been included.

Cleaning Fossils by Ultrasonic Waves

AN important article by Mr. J. N. M. Firth in the *Museums Journal* of April describes the cleaning of fossils in various types of matrix by ultrasonic waves. The instrument used was a 500-W. 'Soniclean' generator, type 1150, manufactured by Dawe Instruments, Ltd., and the cleaning tank of 1½ gallons was made of welded stainless steel. The specimen was either placed in a glass beaker containing cleaning fluid and floating in the tank or was suspended directly. A temperature of 65° C. was found to give the best results, and a few drops of liquid soap added to the fluid decreased the surface tension. It was also found advisable to replace the cleaning fluid when it became dirty, as such particles tended to damp out the waves. From a series of experiments, it would appear that there is a short interval of time at the start of treatment during which most of the dirt adhering to the specimen is removed. This is followed by a period of no further appreciable cleaning and finally by gradual degradation, the time for which depends on the lithological properties of the specimen.

Royal Geographical Society Research Fellowship

DR. P. SALWAY, Research Fellow of Sidney Sussex College, Cambridge, has been awarded a Royal Geographical Society research fellowship for work on the geography and topography of the Roman Fenland. During past years the progressive desiccation of the Fenland has revealed an extensive system of Romano-British farms and settlements, with associated field-systems, droveways and water-courses, both artificial and natural. Continued desiccation will obliterate most of these before the end of the century. There is no part of the surface of Great Britain where the details of an ancient landscape can be so completely recovered as in the Fenland, and one product of Dr. Salway's research and field-work will be a detailed map of the region as it was in Roman times. The fellowship has been established by the Society with the aid of a grant from the Marc Fitch Fund.

Ciba Fellowships

THE Ciba Fellowship Trust, which was founded for the purpose of furthering the exchange of ideas between scientists in the United Kingdom and on the Continent, has awarded the following fellowships for the academic year 1960–61: Dr. V. P. Arya (Banaras Hindu University, University of London and the Polytechnic, Zurich), to study in Stockholm (natural products chemistry); Dr. K. Jones (University of Sheffield), to study at the University of Heidelberg (organic chemistry); Dr. B. L. Mordike (University of Birmingham and University of Cambridge), to study at Gottingen (physical metallurgy); Mr. C. N. Banwell (University of Cambridge), to study at Zurich (spectroscopy); Miss P. M. Bryant (University of Oxford), to study at Basle (organic chemistry); Mr. R. Grinter (University of Exeter), to study at Zurich (physical organic chemistry); Mr. W. D. Hamilton (Queen's University of Belfast and University of Birmingham), to study in Yugoslavia (nuclear physics); and Mr. J. R. Miller (University of Cambridge), to study at Munich (inorganic chemistry).

National Science Foundation Awards

THE National Science Foundation has announced the award of 1,200 graduate fellowships in the sciences, mathematics, and engineering for the academic year 1960–61. Successful candidates were selected from 4,696 applicants from all parts of the United States and its territories. Of the awards, 233 were made in the biological sciences, 946 in the physical sciences, including a number in interdisciplinary fields, and 21 awards were made in certain areas of the social sciences. The fellowships enable the holders to attend any appropriate non-profit-making institution in the United States or in a foreign country. The graduate fellowships provide basic stipends (for 12 months) of 1,800 dollars for the first-year level of graduate study, 2,000 dollars for intermediate years, and 2,200 dollars for the terminal year. These fellowships include additional allowances for dependants and tuition, as well as a limited travel allowance.

Royal Society of Arts: Industrial Arts Bursaries Competitions

THE Royal Society of Arts has issued a report on the Society's annual Industrial Arts Bursaries Competition for 1959, in which 653 candidates from 81 schools and industrial establishments entered the 17 sections (pp. 56. London: Royal Society of Arts, 1960). A total of 34 bursaries amounting to £4,425 was awarded and the report includes the reports of the individual juries. Two inquiries were conducted by the Industrial Arts Bursaries Board in connexion with these competitions during the year. The replies to the first inquiry, which covered those directly concerned with the competition, including the principals of some twenty of the larger schools, indicated that the overwhelming majority considered the competition was doing useful work and that the Society should continue to organize similar competitions. Many suggestions for the extension of the competition to cover a wider range of industrial and commercial needs were also received. The second inquiry was into the subsequent careers of winners of bursaries since 1946. Most of these young designers attribute their present employment, at least in part, to their success in these competitions, and all pay tribute to the opportunity which the bursaries provided, at the outset of their careers, to broaden their outlook and experience.

Nato Meeting on Ionospheric Research

Greek national authorities have invited the Ionospheric Research Committee of the Nato Advisory Group for Aeronautical Research and Development to hold its next meeting in Athens during June 20–23. The four-day meeting will be devoted to discussions on radio-wave absorption. Among those who will be presenting papers are Mr. J. Ratcliffe (University of Cambridge); Mr. Finn Lied, director of the Norwegian Defence Research Establishment; M. Nicolet, director of the Centre National de Recherches de l'Espace (Belgium); and Prof. Vassy (Université de Paris). Further information can be obtained from the Advisory Group for Aeronautical Research and Development, Organization du Traité de l'Atlantique, Palais de Chaillot, Paris, 16.

Summer Courses in Western Europe

Two publications have recently become available concerning summer courses in Western Europe. "Residential Short Courses" is a six-monthly calendar issued by the National Institute of Adult Education and covers short courses to be held, during the summer, in Britain. "European Calendar of Short Summer Courses" covers a similar field of courses to be held in Western Europe as a whole, and is issued by the Bureau Européen de l'Education Populaire (Notes et Etudes, No. 15). Both publications are available from the National Institute of Adult Education, 35 Queen Anne Street, London, W.1, price 1*s*. each (postage 6*d*.).

Announcements

Prof. R. L. Wain, professor of physical sciences in Wye College (University of London), has been awarded the Research Medal of the Royal Agricultural Society of England.

Dr. C. J. T. Cronshaw has been awarded the Hinchley Medal of the British Association of Chemists for his great services to the chemical industry while head of the Dyestuffs Division of Imperial Chemical Industries, Ltd.

Mr. Leslie T. Morton, librarian of the National Institute of Medical Research, Mill Hill, London, N.W.7, has been given the Marcia C. Noyes Award of the Medical Library Association of America for his outstanding services to medical bibliography and librarianship. This Award has hitherto only been made to medical librarians in the United States.

Honorary fellowships of the Royal Aeronautical Society have been conferred on Prof. W. J. Duncan, professor of aeronautics and fluid mechanics at the University of Glasgow and chairman of the Aeronautical Research Council; and Sir George Edwards, managing director of Vickers-Armstrongs (Aircraft) Ltd., and a past president of the Society.

Dr. W. J. Kroll of Corvallis, Oregon, has been appointed the sixth Castner Memorial lecturer and will deliver his lecture, entitled "The Fusion Electrolysis of Titanium", in Glasgow on October 7. Further information can be obtained from the Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

The German Academies and the Austrian Academy of Science have announced that an edition of the letters of Alexander von Humboldt (1769–1859), the German naturalist and traveller, is in the course of preparation. Owners of any letters by Humboldt or addressed to him are invited to communicate direct with Prof. Dr. H. Ertel, chairman of the Alexander von Humboldt-Commission, Deutsche Akademie der Wissenschaften zu Berlin, Berlin 6, Germany.

The fourth volume of the *Journal of Electronics and Control* contains interesting papers on plasma physics and on recent developments in the theory of transistors. A particularly interesting research note describes a switching diode, using gallium arsenide, in which hole storage effects have been so reduced that transition is less than two milli-micro-seconds.

A symposium on recent developments in the applications of nuclear science for peaceful purposes will be held in Hauradan, Iran, during July 6–19. Further information can be obtained from Dr. M. L. Smith, CENTO Institute of Nuclear Science, P.O. Box 1828, Tehran, Iran.

The annual Electronics and Instruments Exhibition and Convention of the Institution of Electronics is to be held, at the Manchester College of Science and Technology, during July 7–13. Further information can be obtained from W. Birtwistle, general secretary of the Institution of Electronics, 78 Shaw Road, Rochdale, Lancs.

A joint meeting of the Challenger Society and representatives from the Marine Laboratories (Development Commissioners Scheme) will be held in the Department of Zoology, University of Cambridge, during June 23–24. Further information can be obtained from Dr. R. Bainbridge, Department of Zoology, Downing Street, Cambridge.

The Nutrition Society is holding a symposium at Rothamsted Experimental Station, Harpenden, on "Food Losses in Field and Store", on July 2. Further information can be obtained from the honorary programmes secretary of the Nutrition Society, Miss D. F. Hollingsworth, at the Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, London, S.W.1.

An international conference, the first of its kind, is to be held on "Congenital Malformations" by the International Medical Congress, Ltd., at Church House, Dean's Yard, Westminster, London, S.W.1, during July 18–22. Further information can be obtained from the Secretariat of the First International Conference on Congenital Malformations, 67 New Bond Street, London, W.1.

Erratum. In the note entitled *Instrument Abstracts* in *Nature* of April 30, p. 359, it is stated that the issue dated January 1960 is No. 1, Vol. 1; this is incorrect. It should read: No. 1, Vol. 15.

U.S. NATIONAL ACADEMY OF SCIENCES

MEDALS AND AWARDS

THE following awards by the U.S. National Academy of Sciences have been announced: The James Craig Watson Medal, to Prof. Yusuke Hagihara, formerly professor of astronomy in the University of Tokyo and director of the Tokyo Astronomical Observatory and later professor in Tohoku University, a post from which he has just retired. Prof. Hagihara is best known for his original contributions to the field of celestial mechanics, the study of celestial bodies in motion. Perhaps his most significant work has been his paradigms for the general problem of the stability of motion—a basic question in celestial mechanics. Prof. Hagihara's mathematical talents have also been turned to one of astronomy's most vexing puzzles—the restricted problem of three bodies. Astronomers have long sought, without complete success, to calculate the relative motions of three bodies when given the positions and motions of the bodies at a point in time. Celestial mechanics is not the only astronomical field of interest in which Prof. Hagihara has gained distinction. He has also made original contributions to theoretical astrophysics, the theory of relativity, and solar eclipses. A prodigious scientific author, he has published more than twenty-five papers and monographs on celestial mechanics alone, and is the author of ten books on various astronomical subjects.

The Agassiz Medal, in recognition of original contributions to the field of oceanography, to Dr. Anton Frederick Bruun, of the University of Copenhagen. Dr. Bruun is a leading authority on life in the deep sea, and has won similar distinction as an effective leader of oceanographic expeditions. In addition to the many expeditions in which he has participated, Dr. Bruun led an expedition during 1945–46 to tropical West African waters, and, during 1950–52, headed the *Galathea* expedition that circled the globe in a study of the ocean deeps. At present, he is directing an expedition to the South China Sea, sponsored jointly by the Scripps Institution of Oceanography and the International Co-operation Administration. It was the *Galathea* expedition that earned Dr. Bruun especial acclaim for his ability to enlist scientists from many nations in a co-operative research programme. Although a voluminous series of reports has already resulted from the *Galathea* findings, it is anticipated that additional reports will be published for many years to come. One of the expedition's most significant achievements was its trawling of the approximately 34,500-ft. deep Philippine Trench, just east of the Islands. Most dramatic finding of the *Galathea* expedition was the discovery of a 'living fossil', the mollusc *Neopilina*, the nearest relatives of which were thought to have become extinct some three hundred million years ago (*Nature*, 179, 413; 1957). During 1926–33, Dr. Bruun was engaged in oceanographical research as a member of the Danish Fisheries Commission. In 1933 he was appointed curator of molluscs in the Zoological Museum of the University of Copenhagen. He has also held appointments at the Carlsberg Laboratory, the Marine Biological Laboratory, and the Danish Aquarium.

The Kimber Genetics Award, to Prof. George Wells Beadle, professor of biology and chairman of the division of biology at the California Institute of Technology. Prof. Beadle's specific research interests have been, successively, the genetics and cytology of maize; the genetics of *Drosophila melanogaster*; the chemistry and the biology of eye pigment in *Drosophila*; and the chemical genetics of *Neurospora crassa*, or red bread mould. Perhaps the most significant result of his work has been the finding of new ways to trace the action of genes. The best-known of these techniques is the use of *Neurospora* to follow the steps by which genes influence the synthesis of vitamins, amino-acids, and other basic ingredients of life. This simple and ingenious tool was developed by Dr. Beadle in collaboration with Dr. Edward L. Tatum and others. Prof. Beadle has occupied his present chair at the California Institute of Technology since 1946. Previously, he was professor of biology at Stanford University during 1937–46, and assistant professor of genetics at Harvard University during 1936–37. Prof. Beadle has been elected a foreign member of the Royal Society of London this year.

The J. Lawrence Smith Medal, for outstanding investigations of meteoric bodies, has been awarded to Dr. E. J. Öpik (*Nature*, April 23, p. 280).

The Public Welfare Medal of the National Academy of Sciences has been awarded for "eminence in the application of science to the public welfare" to Dr. Alan T. Waterman, director of the National Science Foundation. Established in 1913 by Mrs. Helen Hartley Jenkins in honour of her father, Marcellus Hartley, the Public Welfare Medal is considered to be the most distinguished of the Academy's medals. It is unique among them in that it is awarded for outstanding public service in the uses of science, rather than for achievements within a particular scientific discipline.

SIXTH-FORM SCIENCE AS A PREPARATION FOR UNIVERSITY WORK

IN March 1958 the Senate and Council of the University of Birmingham approved a proposal for an inquiry to be held into the suitability of the General Certificate of Education (Advanced Level) syllabuses in science as a preparation for direct entry into first-degree courses in the Faculty of Science. This useful report, now published, was financed by the Gulbenkian Trustees. The subjects under consideration were biology, chemistry, geography and geology, mathematics and physics. The Panel began its work by considering what sixth-form training would be most valuable to a pupil who proposed to enter a first-degree course in a biological subject[*].

It was felt to be essential, in view of the increasing emphasis on the experimental aspects of biology, that such pupils should acquire an understanding of the basic sciences—chemistry, mathematics and physics. They should preferably study biology, but the Panel would not exclude from a university course those whose only background was a sixth-form knowledge of the three other subjects. "Intending biology students should be taught to practise the scientific discipline of observation and deduction, and to despise that pointless accumulation of facts and terms which sometimes passes for scientific education and they should be given training in clear, purposeful and accurate descriptive writing in their own language". The Panel was impelled by two main considerations to pronounce against botany and zoology and the current biology, and in favour of a single, revised course in biology, which should stress the underlying principles of the subject and show the fundamental similarities of living things as well as the fundamental differences between plant and animal.

The present chaotic system of examinations at Ordinary, Advanced and Scholarship levels, with different requirements from each Board, is critically considered, and so useful proposals are made towards a more rational system. The approach of the teacher to the syllabus is largely determined by the type of examination paper which is set. Although the marking of a large number of scripts by many examiners is not easy, and this has led to the use of questions which can be marked quickly and precisely, these questions may not be of the type best suited to selecting the best candidates.

At present, selection for entry to university is made on the basis of Advanced-level performance, supplemented by an interview. The latter occasionally reveals that a student with good marks depends on a particularly good memory and that this kind of entrant usually fails to maintain his performance in the university. It was felt that the introduction of Scholarship-type questions would enable a distinction to be made between the fundamentally sound pupil and the 'memory-man'. In general, there is a remarkable parallelism between the weaknesses, difficulties and suggested remedies in all the subjects. Very useful suggestions are made towards the teaching of fundamental principles, and the eschewing of the unintelligent learning of masses of factual snippets. The report of the Panel is so detailed and yet succinct that further summary is not possible.

This report throws into relief the need for other investigations. Each university can have its own pre-requisites for entry to its courses, and, in this matter, there are differences in standard and scope between science subjects. This makes difficulties for the sixth-former who, in the hope of securing entrance to a university, applies to a number of them. While it is impossible, and if it were possible it would be undesirable, to secure uniformity in this matter, much wastage of effort (even clerical effort), confusion and disappointment result.

It is hoped that other universities will issue similar reports, for the matter is both socially important and urgent. Although it is outside the terms of reference of the present report, there is a more general problem of a parallel nature which is receiving some attention in an inquiry of which the results are awaited. Too many sixth-form students, who seem to promise much, fail to do well at the university. This is a source of disillusion, a wastage of brain-power and money, and a failure to meet social needs, which needs careful investigation and, if possible, a remedy.

There are other matters which should be considered, though these are outside the scope of the present report. For example, there is the failure of the less-than-brilliant sixth-form student to adjust himself quickly enough when he comes to the university with its short terms and social temptations presented by the Students' Union, the failures to use the vacations adequately and the early dates of the examinations in the last undergraduate year. The shortages of good sixth-form teachers, particularly of science and mathematics, and even of good examiners are other, but nevertheless important, matters.

W. L. SUMNER

THE NEEDS OF UNIVERSITY STUDENTS

IN a memorandum submitted to the University Grants Committee, the National Union of Students describes its attitudes to the problems involved in university expansion. Because of their direct experience, the views of the National Union of Students are likely to be of greatest significance where it discusses the needs of students. It has recently suggested, for example, that if adequate and suitable accommodation, which may be of many different kinds, cannot be provided near at hand for the whole student population, then neither the expansion of an existing university nor the establishment of a new one should be allowed (Memorandum to the University Grants Committee on the Expansion of University Education, 1960–1970. Pp. 12. London: National Union of Students of England, Wales, and Northern Ire'and, 1960). Insufficient attention has been paid to this problem in the past, with consequent harmful effects on the undergraduate, as a person and as a student, and upon the community of which he is a member.

While there is a variety of different types of accommodation which fulfil the needs of students, great benefit is derived from time spent in residence. Ideally, halls of residence should be composed of comparatively small units of ten to fifteen rooms, each providing a small kitchen and a discussion room. The units are often well arranged on staircases with small groups of rooms on each floor. There might be three such units on each of three or four sides of a small court, so that each block provided accommodation for some 150 students. There is, however, a considerable range of ways in which good residential accommodation can be provided; the student flats at King's College, Newcastle, and the Studentenhaus at West Berlin University are examples of such variations. There is considerable scope for experiment in this field.

When planning residential accommodation, the architect should consult fully with the university authorities and with student representatives to ensure that the most economic as well as the most effective lay-out is obtained, encouraging the corporate spirit of the university as well as facilities for private study and relaxation of the individual student.

Since the provision of enough residential places is economically unattainable in the near future, the Union emphasizes that not all forms of lodging are necessarily suitable for students, who need a quiet room for study, flexible hours and a sympathetic atmosphere. Lodgings that may suit some purposes can be quite unfitted for study. In a small town such as Aberystwyth, where the university dominates the life of the community, students often find that landladies come to understand their needs and take a real interest in providing the right environment for study. If the university atmosphere and community is to develop, all accommodation should be in close proximity to the university centre.

Another important factor is the academic and administrative structure of the university. Apart from the fact that this can determine the success or failure of its development as a community, it will have repercussions on the breaking down of faculty or departmental inter-relationships, which is already taking place through increased specialization; it will also affect the balance of Faculties and of undergraduate/postgraduate ratios. The structure most conducive to a fully integrated university education is the collegiate structure as will be developed at Bristol. In the expansion of existing universities it may well be desirable to avoid the piecemeal addition of extra sections to the present structure, but rather to change to the collegiate pattern.

All the major buildings of the university—halls, union building, laboratories, libraries, lecture theatres and refectories should be grouped together on one site. It would be valuable if a few small buildings in the various towns selected as new university sites could be leased to the university for use as, say, libraries for the smaller Faculties, and as staff houses where some tutorials could be given; arrangements might also be made for the designation of a university church within the town. Such facilities should not be allowed to detract from the creation of a single university unit.

There should be some degree of specialization in each university in selected areas of study. Such specialization could build up a reputation, encourage research, simplify application problems, attract interested staff, and might also prevent duplication of capital costs on research equipment. Development should be considered in relation to the paramount need to operate a proper tutorial system.

The major need of students is adequate provision for the development of an active student community. There should be a Students' Union building, providing a meeting place and a centre of student life, which should, where possible, be a separate building.

Where new laboratories are being erected, these should be designed in conformity with good safety regulations. It is also hoped that the need for an adequate and well-equipped clinic is generally recognized. These are already provided in many universities, and will be essential in new universities where the treatment of physical or mental illness should not be left to the care of local doctors who might not be readily accessible.

SENSORY SPECIALIZATION IN RESPONSE TO ENVIRONMENTAL DEMANDS

THE third of a series of Zoological Society of London symposia was held on March 4 under the title "Sensory Specialization in Response to Environmental Demands". It was organized by Prof. O. Lowenstein, and the meeting was held under the chairmanship of Prof. R. J. Pumphrey.

In his introductory remarks, Prof. Lowenstein directed attention to the somewhat Lamarckian ring of the title; but he envisaged that none of the topics under discussion would make it necessary or desirable to infringe neo-Darwinian orthodoxy. Outlining the rationale of the programme, he went on to point out that two different types of adaptive specialization could usefully be surveyed in this context. The first may affect the whole range of sensory modalities as a means of adapting an animal to a successful integration into a sub-social or social organization. This type is found, for example, in locusts and to a more extreme degree in the social Hymenoptera. The second type of sensory specialization may be confined to one sense organ only, the eye in nocturnal, deep sea, or cave animals, or the ear in animals like bats and cetaceans which find their way about by means of sonar.

A comparative analysis of sensitivity limits may also reveal instances of adaptation to special environmental circumstances. The sensitivity limits of photo-receptors may serve to illustrate this point.

In a paper on the sensory equipment of the migratory locust, Dr. P. T. Haskell (Anti-Locust Research Centre, London) showed that special sensory adaptations are related to the control of steady and stable flight of the swarming insect and to the maintenance of cohesion between locusts in the swarm. 'Dorsal-light' reaction of the compound eye and proprioceptive feed-back from receptors on the cervical hair plates control anti-roll stabilization, whereas anti-yawing responses are elicited by cephalic hair sensilla. Preferred inter-locust distance in the swarm is maintained by an equilibrium between visual attraction and repulsion in response to auditory and other mechanical stimuli.

Fully social organization as shown by the social Hymenoptera involves a number of instances of extreme sensory specialization in the various castes of ants and bees. Dr. H. Kalmus (Galton Laboratory, University College, London) described some new results concerning colour vision and odour discrimination in the honey bee. Whereas scent is an important item of information in bee-to-bee communication, symbols for colour are very likely missing from the 'vocabulary' of the social insects. A discussion of the mechanism of analysis of the plane of polarized light was illustrated by an electron-micrograph of an insect ommatidium. Dr. Kalmus suggested that the chief sensory adaptation in the social Hymenoptera consists of a co-adaptation of pre-existing sensory mechanisms with patterns of motor activity into systems of communication.

In a paper on the sensitivity limits of photoreceptors, Dr. F. H. C. Marriott (Department of Physiology, Oxford) stressed the necessity of presenting measurements of spectral and absolute threshold sensitivity in such a form that they can be compared throughout the animal kingdom. Such measurements made on five species, namely, man, cat, owl, the amphibian *Xenopus*, and the flatworm *Dendrocoelum*, were discussed and compared with special reference to the differences in the visual sensory structures.

Dealing with the problems of the sensory aspects of adaptation in cave animals, Dr. G. Thines (Laboratory of Experimental Psychology, University of Louvain) gave a paper on sensory degeneration and survival in cave fishes. After a critical discussion of the general idea of evolutionary 'progress', Dr. Thines defined regressive changes as a gradual reduction of independence leading to the 'abnormal' character of regressive faunas such as cave fishes. The survival value of regressive changes in photoreceptors in cave fishes was then assessed and this led to the introduction of the hypotheses of 'remanence' and 'vicariance' with regard to the significance of the continuation in eyeless cave fishes of the pre-existing epigean photokinetic functions and of the supplanting of the functionally insufficient eye by the pineal organ. Dr. Thines then showed a short film on the blind fishes of Somaliland.

The design of fish and cephalopod eyes in relation to their environment was discussed by Dr. E. J. Denton (Marine Biological Laboratory, Plymouth). The density, the refractive medium, absorption and scattering of light by the medium all have their effect on the morphology and functional characteristics of the eyes of marine animals. At greater depth and at night the light emitted by luminescent animals may be more important than the light coming from the sky. Light will only be 'useful' for vision if it can be absorbed by photosensitive pigments. Pigments then play an important part in the adaptive specialization of eyes. The elongation of the rods of the deep-sea fish retina, although raising sensitivity, could have an adverse effect on visual acuity were it not for the existence in these elongated rods of marked channelling of light along the rod. Pigment migration between rods also diminishes the blurring effect of lateral spread of light.

The symposium ended with an account by Prof. F. P. Mohres (Department of Comparative Physiology, University of Tubingen) on sonic orientation of bats and other animals. Prof. Mohres recounted how, during the Second World War, Spallanzani's classical observation of orientation of bats in the dark found its explanation in the simultaneous discovery of ultrasonic echo-location in the vespertilionid bats by Griffin, Pierce and Galambos in the United States, by Dijkgraaf in Holland and by himself in Germany, all of them confirming a hypothesis advanced by Hartridge in 1922. In vespertilionid bats short volleys of ultrasonic pulses of a broad and irregular frequency spectrum are utilized in a system of time difference estimation in which the time difference between the emitted signal and its returning echo is a measure of the distance of the reflecting object, and the time difference between the arrival of the echo at the two ears serves as a measure of direction. A completely different sonar mechanism of orientation was, however, discovered by Prof. Mohres to exist in the horse-shoe bats (Rhinolophids). While flying, the horse-shoe bats keep their mouths closed and the horse-shoe points in the direction of flight, or in stationary animals into the direction of 'interest'. Ultrasonic sound, consisting of prolonged cries without frequency or amplitude modulation, is emitted through the nostrils and cast about in a beam 'focused' by the horse-shoe. In Rhinolophids the essential feature of ultrasonic orientation is thus, according to Prof. Möhres, not a time difference but an intensity-difference estimation. The animals are thus believed to assess the sound intensity of their orientation cries reflected by objects in their environment in turning their ears point to point through the range of space under scrutiny. Rendering the ears immobile abolishes successful orientation. It must be mentioned here, however, that certain aspects of the *modus operandi* of sonar as summarized by Prof. Mohres are meeting with adverse criticism from a number of quarters.

Finally, Prof. Möhres described how a search for mechanisms intermediate between the vespertilionid and the rhinolophid extremes led to the discovery of intermediate situations in the Hipposideridae and the Megachiroptera (fruit bats). However, no conclusive phylogenetic picture emerged, and the origin and ways of the evolutionary lines remain hidden in the darkness of the past.

O. LOWENSTEIN

ASPECTS OF OROGENS

THE Geologische Vereinigung held its fiftieth anniversary meeting under the presidency of Prof. G. Fischer in Würzburg during March 12–14. The theme for discussion was the Orogen, the mobile belts or those parts of the Earth's crust in which mountain chains are formed. The process of orogeny can best be considered in respect of time; a time when the materials accumulate and become compacted to form the building materials for the mountains; a time when these rocks are disturbed by forces usually regarded as being produced by shrinking of the Earth's surface; and a time when magmas from deeper horizons within or below the crust break through and pierce the strata whether quiet or crumpled and broken. Part of the magmatic activity consists of the release and movement of reagents which metamorphose the sediments. Then comes a final act in which vertical movements are considerable, helping to account for the present stature of the mountains and their wild or orderly scenery by exposing the various structures to erosion.

There is also a space relationship. The orogens are restricted to comparatively narrow belts in which mountain building takes place. The arrangement of the mountains within these belts is not simple or regular. One reason for this is that earlier chains may have stood along or across the line followed later by younger mountains, and their presence, or that of broken fragments of these old ranges, interferes with the growth and orientation of the later ones. The structures themselves may be divided into those formed under comparatively little cover and therefore at low pressure, and others which have formed deep in the crust under high pressure. The former are more often well exposed in present-day mountains, but the latter are seen only where erosion has been unusually deep. The former have often escaped intrusion, but the latter have suffered magmatic injections and are in part complicated by metamorphism.

The forces at work within the orogen also vary. Opinions diverge as to what initiates the commencement of growth, and it is probable that tension played a part. Lateral compression undoubtedly was important during much of its life and resulted in the formation of the folds and associated thrust-faulted structures. At a late stage, however, tension again developed and allowed normal faults to form accompanied by floods of lava or the great sheets of tuff or volcanic ashes.

Most of the papers delivered during the meeting by some 35 speakers were orthodox enough, but one by Dr. L. Egyed (Budapest) seemed more than a little heretical to some in the audience. He suggested that below the layers of ultrabasic rocks reputed to underlie the sima, there exists less-basic material; magma containing water and other light fugitive constituents which are absent from peridotites. Such ideas appear to be in accord with Dr. Egyed's published views that the Earth is an expanding body, not the contracting one, described, for example, by the late G. M. Lees, which is how many other geologists would have it.

In the opening paper Dr. R. Trumpy (Zurich) remarked that no scheme of mountain building as yet worked out can be applied generally. Each orogen has to be treated as an individual. As well as the disturbing influence exerted by fragments of earlier mountain-chains the type of sediments involved played an important part in determining the shape of the resulting structures. For example, the thick column made up of alternating thin beds of muds and sands, characteristic of eugeosynclines, fold in a totally different style from that found where the strata are mainly thick bodies of limestone and sandstone such as accumulate in miogeosynclines. Examples to illustrate his opinions were chosen from the western Alps which, although well known, are complicated and are by no means typical of structures in some other orogens. Dr. E. K. Walton (Edinburgh) described the eugeosynclinal region of the Scottish Southern Uplands where the Ordovician and Silurian strata are now regarded as being thicker than was previously estimated and as including higher stages in the Silurian than those hitherto recognized there. Broader asymmetrical folds with steep thick flanks and disturbed by large strike faults are commoner structures than the groups of innumerable isoclinal folds depicted in the classical sections by Peach and Horne.

The spilites of the Lahn–Dill region discussed by Dr. H. Hentschel (Wiesbaden) contain albite, chlorite, quartz and calcite instead of the normal minerals of a basaltic suite, plagioclase, pyroxene and olivine. The possibility that sea water entangled among the geosynclinal sediments reacted with basaltic intrusions is considered as probable.

The veteran Dr. P. Eskola (Helsinki) referred to juvenile granites produced by intrusive magmas formed from components from within the Earth which have diffused outwards. These he contrasted with secondary granites derived from re-working of metasomatized sediments or migmatites. These may appear as disharmonic stocks even in epeirogenic regions. The presence of an aureole of contact metamorphism serves to demonstrate cases in which a hotter intrusion pierced a colder environment.

Because the bodies of sial and sima extend laterally as sheets which are nearly horizontal it is easier to imagine the movement of material along rather than across them, but where they are in an unusual relationship, such as occurs near the edge of an orogen where it touches the margin of an ocean basin, transverse movement of magma should be easier. Dr. P. Michot (Liège) directed attention to the importance of such marginal intrusions and suggested that they may originate at depth in the katazone. Now that methods have been devised enabling rapid analyses to be made, Dr. K. R. Mehnert (Berlin) considered that a new and important research tool is available which may be applied to the study of the distribution of alkalis throughout the body of an orogen. Dr. H. Borchert (Clausthal) also spoke of geochemistry, referring to the association of the copper, zinc, lead and barium ores on one hand and chromium, nickel and titanium ores on the other.

The complicated structures of the Central Pyrenees, involving the interpretation of areas with slaty cleavage and of orientation patterns assumed by newly formed metamorphic minerals, were described by Dr. H. J. Zwart (Leyden). Dr. E. Bederke (Gottingen) considered the relationship between stress and regional metamorphic effects. He cited examples from the Sudeten hills and western Alps in which active phases of disturbance were separated by long intervals of quiet. The late history of the orogen was the theme of Dr. A. J. Pannekoek's (Leyden) discourse. Folding, faulting and differential vertical movements contribute to the present morphology. Theories of mountain building should be capable of explaining the late movements as well as other early ones. The association between late movements and post-orogenic vulcanism suggests the intervention of a magmatic process. The breaking down of a basin like the Mediterranean with excess gravity may be connected with the uplift of neighbouring hills and be independent of the structure of the orogen.

Dr. A. Winkler von Hermaden (Graz) described examples of structures from the western Alps and Croatia, while others chose examples from central Asia, central Africa, the Carpathians, the Balkans, the east Alpine zone and the Ligurian Alps with part of the neighbouring northern Apennines. The object of four other papers was to make use of features seen in Central and South America to show that structures there run nearly parallel to the present coast; that there has been deposition and folding along an old mass lying to the east; that breaking down accompanied by intense vulcanism and intrusion has produced a graben-like feature a little inland from the coast; and that large uplifts have taken place rather recently. The frequent earthquakes both out at sea and up to 100 miles inland are taken to indicate that the region is still tectonically active.

During the session the Steinmann Medal was awarded to Prof. H. H. Read. The text of the contributions made by the several speakers is expected to appear in the next volume of the *Geologische Rundshau.*

J. V. HARRISON

INDIAN INSTITUTE OF SCIENCE, BANGALORE

GOLDEN JUBILEE SYMPOSIA

As a part of scientific activities during the Golden Jubilee Year (1959–60) of the Indian Institute of Science, Bangalore, which was inaugurated in February 1959, the Department of Chemical Technology and Chemical Engineering arranged symposia on "Hydrocarbon Synthesis and Hydrocarbon Conversion" and on "Mass Transfer" during January 11–13, 1960. The technical session commenced with an address by Prof. W. Groth, director of the Physical Chemistry Research Institute, University of Bonn, who discussed new developments in the field of emission mass spectroscopy. A number of original papers covering different aspects of the two subjects of the symposia were also read and discussed. Papers were presented by scientists from the United States, the United Kingdom, Germany and Italy, as well as from many Indian universities and institutions.

In the session on hydrocarbon synthesis a paper on the "Performance of Iron Catalysts and the Promoter Action of Alumina and Platinized Asbestos at Atmospheric Pressure" was presented in which the authors indicated that alumina behaved as a structural promoter and increased the polymerization activity and hydrocracking, whereas platinized asbestos improved the overall activity and hydrogen consumption, keeping the formation of gaseous hydrocarbons low. Papers on "Fischer–Tropsch Synthesis in Fluidized Bed" using an Fe–Cu–MgO–K_2O catalyst and the "Rheinpreussen–Koppers Liquid-phase Process" were also read. In the former method the performance compared favourably with the already established units. In the latter process the authors reported considerable selectivity for C_3 hydrocarbons and versatility to suit the market requirements. A probable mechanism of Fischer–Tropsch synthesis based on intermediate reactions of the carbonyl and oxo-complex types was reported and discussed. The possibility of producing gas from methane-rich low-temperature carbonization gas using a nickel catalyst with a high conversion (92 per cent) at a temperature of 900° C. was reported. The paper on "Rectisol Process for Gas Ultra-purification under Elevated Pressure" indicated the advantage of simplicity of operation in a single unit.

Concerning hydrocarbon conversion, reformation by hydrogenation, cracking, etc., a number of interesting papers were presented. The medium pressure hydrogenation of coal-tar distillate with a desulphurization catalyst was reported to have resulted in the formation of a refined product which could be used as a starting material for the chemical industry or as motor fuel. The results of cracking of high boiling fractions from Nahorkatiya crude oil over a silica–alumina catalyst showed yields of high percentage of middle distillates. The use of the same catalyst promoted by calcium oxide for the production of lubricating and diesel oils from paraffin wax from Assam crude oil was also reported. The gasification of hydrocarbon oils for conversion into gases of high B.T.U. by cracking over various contact beds, including activated coke and in an atmosphere of carbon dioxide, indicated the possibility of developing a single-stage continuous process for preparing gas of uniform composition and for meeting standard requirements. One paper dealt with the structural features of reactants on the basis of which predictions could be made regarding the reactivity and nature of products obtainable in the alkylation of olefins with paraffins and alkylbenzenes under pressure. There were three papers dealing with oxo-reactions. In one paper, the author reported the synthesis of propionaldehyde, propionic acid and methyl and ethyl propionate by the oxonation of ethylene. The other two papers dealt with the thermodynamics of oxonation of butenes, preferential oxonation, etc.

In the session on mass transfer a number of interesting papers were presented, some of them dealing with isotope separation. The separation processes based on ion-exchange methods with special reference to band displacement and elution principles, including elution chromatography, were reviewed and their application to separation of low- and high-mass numbers up to calcium was discussed. The processes for production of carbon-13, nitrogen-15 and oxygen-18 were also surveyed. The derivation of a relationship for the calculation of transfer columns for heavy-water enrichment plants, and the comparison of the theoretical and experimental values obtained in case of Bitterns water were discussed. A simplified and experimental modification of the temperature-float method, as developed recently, was described and discussed with reference to such factors as float design, horizontal and vertical temperature gradients in the float chamber, etc., for isotopic analysis of heavy water. Based on experimental data, the possibility of co-current distillation in a gas stream for the enrichment of heavy water was indicated. The theory of separation potential of thermally controlled gas centrifuges, and some experimental results obtained from centrifuge models *ZG*3 and *ZG*5 for separation of argon, xenon and krypton isotopes were presented.

A method of determining the mass transfer rates by means of a single particle placed in a bed of similar-sized inert particles by radioactive tracer technique and the application of the same in the case of ion-exchange processes was described. The results obtained in the steam-stripping of carbon dioxide from sodium carbonate–bicarbonate solution in perforated plate columns indicated that the liquid hold-up in the column is chiefly a function of the rate of flow of the liquid, which itself is dependent on the decomposition of the sodium bicarbonate during the process. The studies on the mechanism of mass transfer in naphthalene-packed beds indicated that the values of diffusivity coefficients differed from those obtained by other investigators. This was attributed to some other mechanism such as surface resistance, the diffusion of solute molecules, etc., besides the molecular diffusion in the surrounding gaseous film. A generalized correlation of operating hold-up in packed columns, which gave a value within 5 per cent of the observed values in most cases, was discussed. A method has been proposed for the design of a fixed-bed catalytic reactor for vapour-phase reactions based on the reaction-rate constant and the overall heat-transfer coefficient, and on the assumption that there is no radial temperature variation. Dixon-ring packings prepared locally were reported to be highly efficient in laboratory fractionating columns. An empirical equation based on experimental results obtained with a Northrup and Anson diaphragm cell for calculating diffusivity coefficients of organic acids in ethanol–water mixtures was proposed.

A re-cycling pressure-equilibrium still was described in one paper, and the results obtained for benzene–toluene and ethanol–benzene systems up to 200 p.s.i.g. were discussed.

In one paper attempts were made to explain the heat-transfer characteristics of stirred and gas-fluidized beds of particles on the basis of a theoretical model in which the rate of heat transfer from a heated surface in contact with a stirred bed is dependent on the rate of replacement of particles at the surface by particles of 'average' temperature from the bulk of the bed. The experimental results obtained in an apparatus in which circulation of particles was caused by stirring were found to agree with the model proposed.

Some review papers dealing with the theory of air-drying of solids and its application for the design of industrial dryers, separation of hydrocarbons by chromatographic methods, the application of urea and thio-urea complex formation for separation in petroleum industry, the various petroleum-refining processes with special reference to coking, thermal cracking and catalytic cracking, and the recovery of catalytically cracked feed stocks from petroleum residue by propane-decarbonizing were also read.

R. L. DATTA

PSYCHOLOGY OF GIFTED CHILDREN

HIGH intelligence is probably the most valuable of a community's social and economic assets. From gifted individuals come the sources of creativity, of leadership and of progress at all levels—moral, artistic, scientific and political. On the other hand, the highly intelligent maladjusted or anti-social individual can be a greater threat to his fellows and to his society than his less able contemporaries. Thus, the best all-round education and training of the most able group of children and adolescents are essential aspects of the conservation and exploitation of our natural resources. To some extent, the Education Act of 1944 recognized this, crowning nearly half a century of attempts to give able children the right to a fitting education in school, and later in university, irrespective of their social background.

Dr. W. D. Wall, director of the National Foundation for Educational Research in England and Wales, has now examined the knowledge available as a basis for reviewing that part of our educational system and methods which deal with the pool of high ability (*Educational Research*, 2, No. 2; February 1960).

Genius in its fullest sense is of immense importance to any society. As, however, it is very rare, and in any event so little is known about the conditions which produce it, attention must be concentrated on the general pool of high intellectual ability from which will be recruited scientists, teachers, leaders in political and business life and the professions generally. At present in the English educational system it is assumed that this pool is defined by the ability to profit from a grammar school type of curriculum in adolescence. Few of the outstandingly able children now fail to qualify for entry to grammar school.

Our present allocation procedures, however, although generally more efficient than any other form of examination, can take no account of a number of factors which determine potential performance. Virtually a child's education during adolescence and consequently his chances of higher education are determined by the result of five years in the primary school.

Ability, however, as shown in school learning and afterwards by vocational success or social contribution, is only in part determined by strictly genetic factors. 'Operational intelligence' is an innate product of ability and the educational effects of the environment. The ability which psychologists see and attempt to measure in children and adolescents is the sum of inheritance, motivation and nurture. Marked lack of affectionate mothering will result in a lowering of ability, and emotional deprivation in infancy particularly affects the development of verbal concepts and abilities. If this continues beyond a certain point, its effects are irreversible. From the work of the Population Investigation Committee, which is following the growth of some 5,000 children born in 1946, it seems to be indicated that the quality and level of parents' interest in their children markedly affects not merely academic attainment but also the complex general ability measured by intelligence tests. There is, therefore, a proportion of children whose talents never show themselves to the full because the environment starves them in important ways.

General ability and talent well above the average may never declare themselves if nurture is lacking, or if emotional deprivation is marked.

It is difficult to over-estimate the importance of a constructive education at home, and in the school, for able children if they are to realize their intelligence capabilities to the full. However, socially and personally something more than a merely reasonable state of emotional equilibrium is necessary. It is of fundamental importance that highly intelligent children and adolescents should see their high endowment, not as a source of egocentric and purely personal advancement, but as a trust which increases their responsibilities towards others. It is doubtful whether the present stress on inter-personal competition which marks some facets of our educational system is fully desirable; and whether sufficient demands are made upon our ablest ten per cent of pupils.

The notion is still current that genius is maladjusted emotionally, often feeble physically, and that poets, in particular, tend to die young. Similarly, the popular picture of the highly intelligent child presents him as puny and bespectacled, as precocious in language interests as he is retarded in his emotional development, liable to over-fatigue and difficult to get on with. There is little truth in these stereotypes. The able child tends to be superior to the average in every way: there is no law of compensation which offsets high intelligence by inferiorities in non-intellectual fields. The degree of superiority to the average is not the same in all fields and is greatest in those most closely related to intelligence, that is, originality, intellectual interests and achievement test results. Terman's extensive investigations showed that "contrary to the theory that great achievement is usually associated with emotional tensions which border on the abnormal, in our gifted group superior success is associated with stability rather than instability, with absence rather than presence of disturbing conflicts—in short, with well-balanced temperament and freedom from excessive frustrations".

The majority of intelligent children, and particularly the highly intelligent, tend to have interests well in advance of their physical age. Precociously concerned with such things as matters of origin, destiny and evil in the abstract, immature in experience but mature in logic, they rouse the anxiety, antagonism and jealousy of adults. They easily become negatively suggestible, and the illogical conduct of adults may lead to rebellion or to a gathering cynicism.

The difficulties of very able children are most likely to be marked within the middle years during the junior school period, and lessen as age increases the range of social movement, allowing them to seek companions of their own kind and as mastery of educational skills allows them to seek and find the intellectual challenge they need. Our system of progressive selection by academic attainment, though it has many defects, makes it more likely that the able child, even in the primary school, and certainly at the secondary and subsequent stages, will meet his equal and find stimulation. This does not mean that the problem of how the most able one, five or ten per cent of children, should be educated has been solved. This is a matter which is occupying the attention of educators in the United States as well as in Great Britain and Europe.

THERMODYNAMICS AND KINETICS OF SPONTANEOUS GENERATION

IN the current enthusiasm to put forward theories that provide a milieu rich in organic compounds for the spontaneous generation of life, little attention has been given to the quantitative aspect of the problem. One might estimate the rates of reactions producing such compounds, on one hand, from pertinent kinetic data; or one might use thermodynamics as a guide to the quantities of compounds expected, particularly in view of the long times available for approach to equilibrium. In a recent paper[1], however, Miller and Urey apply thermodynamic formulæ only to the equilibrium concentrations of inorganic raw materials in the primitive atmosphere; but they do not apply thermodynamics to the synthesis of organic compounds.

It seemed interesting to me to calculate the equilibrium concentrations of some amino-acids under the conditions postulated by Miller and Urey. For example, the first compound listed in their Table 2, glycine, is formed from the starting compounds by a reaction that may be written:

$$2\,CH_4 + NH_3 + 2\,H_2O = NH_2CH_2COOH + 5\,H_2$$

with an equilibrium constant of 2×10^{-40}. Substituting the partial pressures assumed by Miller and Urey (and taking p_{NH_3} as 0·04 atm.), the aqueous concentration of glycine is 10^{-27} mole/l. Similar calculations for more complex amino-acids yield smaller concentrations.

Now, of course, it is possible that, in an energy-rich medium, steady-rate concentrations can be maintained far from equilibrium. In such case the expected concentrations depend on the available mechanisms for synthesis and decomposition. Ultra-violet light is the most important source of energy to consider, being hundreds to thousands of times more abundant than electrical discharges or ionizing radiation. The atmosphere postulated is transparent to ultra-violet down to 2250 Å.

A glycine molecule formed in such an atmosphere is immediately vulnerable to radiation up to 3000 Å., absorbing in a part of the solar spectrum far more intense than that which produced it. Decarboxylation of activated glycine would presumably occur with a quantum efficiency of the order of unity. Thus, any glycine formed would be rapidly decomposed. Its absorption coefficient, about 0·15 cm.$^{-1}$-(moles/l.)$^{-1}$ at 2500 Å., and the intensity of ultra-violet below 3000 Å., about 0·01 cal./cm.^{2}/min., or 10^{15} quanta/cm.^{2}/sec., give it a half-life of about 30 days. This is much shorter than the half-time of transport from the stratosphere to the surface, now estimated from fall-out data as three years. Thus, 97 per cent of the glycine would be decomposed before it could reach the surface.

Miller and Urey hope to save the synthesized products by removing them from the reaction zone in the atmosphere to the ocean. But even after the glycine reaches the ocean, the victory is not won. Abelson[2] has discussed the possible stability of simple amino-acids throughout geological time; the important effect, however, is not thermal, but decomposition by ultra-violet radiation. The ultra-violet reaching the surface would penetrate to a considerable depth. To-day's sea water transmits 10 per cent of light of wave-length 2600 Å. to a depth of 6 in., and fresh water, which may be more nearly comparable to the primitive ocean, to as much as 3 ft. (ref. 3). In the mixed layer above the pycnocline, about 100 metres deep, glycine would have a half-life to ultra-violet destruction of about twenty years. Even assuming it to be mixed to the bottom of the ocean, with an average depth of 4 km., the half-life is only 1,000 years. These short lives for decomposition in the atmosphere or ocean clearly preclude the possibility of accumulating useful concentrations of organic compounds over eons of time.

The limiting concentrations to be hoped for can be estimated from the steady state between production and decomposition. The rate of formation of glycine by ultra-violet irradiation (1165–1470 Å.) from a mixture of methane, ammonia and water vapour may be estimated from the reported work of Groth and von Weyssenhoff[4]. They were barely able to identify glycine and alanine in the product after exposure to 10^{21} quanta. On the assumption that they could detect $0 \cdot 1$ μgm. of glycine, this gives a quantum yield of 10^{-6}. The flux of solar ultra-violet radiation below 1500 Å. is given as $3 \cdot 5$ cal./cm.^{2}/yr., which corresponds to 3×10^{11} quanta/cm.^{2}/sec. Thus, glycine would be formed at a rate of 3×10^5 molecules/cm.^{2}/sec. During the average life-time in the atmosphere this could build up to 10^{12} molecules/cm.^{2}, or a partial pressure of about 10^{-14} atm. Allowing for 3 per cent to reach the ocean and the 1,000-year life there, the maximum concentration in the sea would be 10^{-12} molar.

This concentration is far from equilibrium. The actual concentrations realized would probably lie between the thermodynamic and the kinetic estimates, that is, between 10^{-27} and 10^{-12} molar; but even the highest admissible value seems hopelessly low as starting material for the spontaneous generation of life.

Consideration of other sources of energy, although they are very much weaker than the ultra-violet radiation, leads to similar conclusions. Thus, ionizing radiation may form complex products from simple reactants, but the more complex and highly organized compounds are more vulnerable to the same agent than their simple precursors. *G*-values of the order of unity are found for the decomposition of proteins by radiation[5]; whereas the formation of protein by radiation has not been observed.

The conclusion from these arguments presents the most serious obstacle, if indeed it is not fatal, to the theory of spontaneous generation. First, thermodynamic calculations predict vanishingly small concentrations of even the simplest organic compounds. Secondly, the reactions that are invoked to synthesize such compounds are seen to be much more effective in decomposing them.

Further, it must be remembered that both lines of argument become quantitatively of an overwhelmingly greater magnitude when organic compounds other than the very simplest are considered. From thermodynamics, the equilibrium concentration of glucose is 10^{-134} at unit activities of the component reactants. The values for the simplest proteins must be unimaginably small. Also, in agreement with the thermodynamic prediction, the kinetic steady-state concentration falls rapidly with increasing complexity of organic compounds, because (1) the quantum yield for their formation decreases; (2) at the same time their stability against thermal decomposition decreases; and (3) their opacity to ultra-violet radiation and decomposition by this means increases. The physical chemist, guided by the proved principles of chemical thermodynamics and kinetics, cannot offer any encouragement to the biochemist, who needs an ocean full of organic compounds to form even lifeless coacervates.

These estimates are not in conflict with the experimental results of Miller and others who have synthesized organic compounds with electrical discharges or ultra-violet light in the laboratory. They have merely used the well-known principle of increasing the yield of a reaction by selectively removing the product from the reacting mixture. But the fact that a chemist can carry out an organic synthesis in the laboratory does not prove that the same synthesis will occur in the atmosphere or open sea without the chemist. The second law of thermodynamics applies not only to inorganic gases in the atmosphere, but also to organic compounds in the ocean. Living cells may reverse the process, but in the absence of life, "die Entropie der Welt strebt einem Maximum zu".

Dr. Hull's analysis of the production and stability of simple organic molecules in a lifeless Earth is a valuable contribution to the discussion on biopoesis. By introducing a quantitative discussion he has effectively narrowed down the range of possibilities and thus presented a much more definite problem to be solved. Others are far more competent to discuss the thermodynamic aspects of this communication, and I would rather question the conclusions that Dr. Hull draws from his arguments.

Even if we accept that small organic molecules, *a fortiori* larger organic molecules, are likely to exist in an atmosphere and open ocean only in very small equilibrium concentrations, it does not necessarily follow that the way of photosynthesis for the origin of even more complex compounds, or of life itself, is effectively barred. The fact that Miller and others have produced such compounds by radiation is, as Dr. Hull quite rightly points out, because these products are selectively removed from their zone of formation. It would seem to follow that if complex organic molecules were ever produced on a lifeless Earth, something similar must have occurred there. There must have been a process which removed a certain proportion of these molecules from their zone of reaction. Further, the same or another process must have concentrated them to the extent where they could enter into still more complex reactions. Such reactions did not necessarily require further energy sources to promote them. In other words, the original concept of the primitive soup must be rejected only in so far as it applies to oceans or large volumes of water, and interest must be transferred to reactions in more limited zones.

Even in the inorganic world, minerals are produced which involve very large degrees of concentration of rare elements, in fact, unless two atoms resemble each other in nearly every particular, as rare earths do, then somewhere in the world a mineral will be found containing mainly that element, however rare. The processes for the concentration of organic molecules may well be similar and equally effective. I have at various times proposed such a mechanism of just such concentration and shielding organic molecules originally formed in an ocean. My first was that of the concentration of molecules directly from sea water in estuarine clays[1]. More recently I have realized[2] that there exists a much more powerful method of concentration of all molecules which have either surface activity or which tend to concentrate in the neighbourhood of water surfaces, that is, effectively all molecules containing alkyl groups. A. T. Wilson[3] has directed attention to the processes of the concentration of organic material derived from dead organisms, first on the surface of the ocean and then, through the action of the wind in foam or spray, along the coasts, thus providing nutriment for benthic organisms. The same processes would certainly have occurred in an abiotic sea in which any mineral hydrocarbons or their oxidized derivatives were to be found. The effectiveness of this process for concentrating tar will not be doubted by anyone visiting a beach in Britain to-day. The probability of the original presence of such hydrocarbons would be much strengthened if the ideas recently put forward by Mason[4] on the formation of meteorites containing hydrocarbons were accepted and extended to the outer layers of a primitive Earth.

By such a two-stage process, a relatively very small bulk concentration of synthetic molecules can be turned into a large concentration in specified areas. Further, once involved in clay, which absorbs such molecules readily, they will be completely shielded from ultra-violet radiation. A further mechanism of concentration of the smaller groups, particularly those containing nitrogen, will be provided by the presence of transition metal ions, notably those of iron, which may also play a part in primitive photosynthesis, as N. W. Pirie has pointed out[5]. One way of verifying or negating these hypotheses would be by extensive experimentation using large volumes of very dilute organic solutions and absorbing them on clay under controlled conditions. Until this is done, it is premature to accept any arguments, quantitative or qualitative, against the spontaneous formation of organisms, indirectly if not directly, from the primitive ocean.

AN ASSOCIATION BETWEEN DENTAL CARIES AND CERTAIN SOIL CONDITIONS IN NEW ZEALAND

By T. G. LUDWIG
Medical Research Council, New Zealand

W. B. HEALY
Soil Bureau, Department of Scientific and Industrial Research, New Zealand

AND

Captain F. L. LOSEE
(Naval Medical Research Institute, Bethesda, Maryland)
Medical Research Council, New Zealand

In 1955 Hewat and Eastcott[1] reported that a relationship exists between prevalence of caries and certain soil conditions in New Zealand, and a general investigation is at present being conducted to determine the causal mechanisms responsible for this relationship.

One phase of this investigation involves the study of the effect on prevalence of caries of recent saline soils at Napier, Hawke's Bay. In 1931 the major Hawke's Bay earthquake resulted in the uplifting of a land mass some 60 miles long and at least 10 miles wide to heights ranging up to 9 ft. The epicentre of the disturbance was situated in the vicinity of Napier, where the shore-line was elevated from 6 to 8 ft., this resulting in the draining of more than 5 square miles of the extensive lagoon adjacent to the city. The saline soils[2] thereby exposed have since been brought into production and in comparatively recent years used for residential development. The preliminary results of our investigation in this area are presented in this report.

During 1954–55, dental examinations were undertaken of children resident throughout life in the adjacent cities of Hastings and Napier to establish a base-line whereby the effectiveness of the fluoridation of the Hastings water supply in reducing the prevalence of caries could be evaluated[3]. The results of these examinations showed that Napier children aged 5–8 years had a considerably lower caries experience than children of an equivalent age in Hastings, this difference being manifested in both permanent and deciduous dentitions. Napier children aged 6, 7 and 8 years had, respectively 57, 46 and 21 per cent fewer permanent teeth with caries experience than Hastings children of the same age (Table 1); and Napier children aged 5, 6 and 7 years had, respectively, 20, 14 and 6 per cent fewer deciduous teeth with caries experience. These differences in prevalence of caries were statistically significant at the 0·1 per cent level.

This finding was unexpected in view of the apparent similarity of conditions in the two cities. Both have populations of approximately 20,000 and are situated in the eastern part of Hawke's Bay, Napier being the

Table 1. Comparison of Caries Prevalence Rates in Permanent Teeth of Hastings, Napier and Palmerston North Children in 1954–55 and in 1957

	Mean No. permanent teeth D.M.F.* per child			
	Hastings 1954–55	Napier 1954–55	Napier 1957	Palmerston North 1957

* Results on oven dry basis. Zero levels mean that the element could not be detected by the method used.

chief port of the province and Hastings lying 8 miles from the sea and about 12 miles from Napier. Rainfall, hours of sunshine, socio-economic conditions, and racial composition of the populations are closely comparable. The reticulated water-supplies (normal fluoride content 0·15 p.p.m.) are drawn from the same artesian strata, and analyses have indicated that the normal mineral composition of the two supplies is similar (Healy, W. B., unpublished results). The cities have a common milk supply. Analyses of urine samples from Napier children have indicated that their lower caries experience is unlikely to be related to the ingestion of fluoride from fish or some unsuspected source, since the mean fluoride content of these samples was 0·15 p.p.m. (Malthus, R. S., unpublished results).

Dental examinations of Hastings and Napier children were repeated in 1957, and it was found that fluoridation at Hastings over a period of about 2½ years had reduced caries prevalence among children to approximately the same level as at Napier. To provide an additional check on the low caries experience of Napier children, dental examinations were made of children resident in the city of Palmerston North, which lies 110 miles south-west of Napier on a similar soil to that of Hastings. The results showed that, in 1957, Napier children up to the age of 10 years had a considerably lower caries experience than Palmerston North children of an equivalent age (Table 1), and that the relationship between caries prevalence in Napier and Palmerston North in 1957 was closely comparable to that between Napier and Hastings in 1954.

Both Hastings and Napier are situated on soils which are derived from similar alluvial materials. However, as a considerable area of soils in the vicinity of Napier has a recent marine history, this appears to be the most likely variable which may have influenced conditions between Napier and Hastings. To test this hypothesis, soil and vegetable samples were collected from five market gardens in the Napier area and from four in the Hastings area.

Analysis of the soils from the two areas shows little difference in total content of some twenty elements as determined by the spectrograph. Differences in soil properties such as exchangeable cations including magnesium and sodium, cation exchange capacity, carbon/nitrogen ratios, and available phosphorus, were comparatively minor in nature and probably reflect management practices of individual market gardens. Very definite differences in *p*H and per cent calcium carbonate were found. Hastings soils had *p*H's of 5·7, 6·0, 6·3, 6·7, while Napier soils had *p*H's of 6·4, 7·5, 7·7, 7·8, 8·1. The three soils with *p*H's above 7·5 contained shell fragments, and gave figures of 2–3 per cent for calcium carbonate.

The vegetables selected were potatoes, carrots, silver beet, French beans, green peas, cauliflower, cabbage, lettuce and tomatoes, since there is evidence to show that these include those most commonly used in the New Zealand diet (Cadell, P., unpublished results). The edible portions showed no marked differences in major elements, but spectrographic analysis of the ash showed some notable differences in trace elements. In general, Napier vegetables were higher than Hastings vegetables in molybdenum, aluminium and titanium, and lower in copper, manganese, barium and strontium. Typical results are shown in Table 2.

Trace elements other than fluoride have been suggested as possible factors in human caries. A high urinary selenium content, which reflects intake, has been associated with a high caries prevalence in humans by Hadjimarkos[4]. On the other hand, Ter Meulen[5], Adler and Straub[6], and Nagy and Polyik[7] have associated high molybdenum-levels in soils or in drinking water with low prevalence of caries in humans, while Adler[8] and Kruger[9] have developed a greater degree of caries resistance in rats by the administration of molybdenum during the period of mineralization of the rat molar. Stookey and Muhler[10] have reported that molybdenum increased fluoride retention in rats. Consequently, it is of considerable interest that our results showed that while molybdenum was detected in the ash of only one Hastings vegetable, it was present in that of the majority of Napier vegetables in amounts up to 9·5 p.p.m. The higher molybdenum content of Napier vegetables is attributed to its greater availability in Napier soils due in the main to higher *p*H.

At present it seems possible that a higher intake of molybdenum may be the prime factor responsible for the lower prevalence of dental caries among Napier children. However, additional studies involving these children, and extension of the investigation to animal experimentation and analysis of vegetables from home gardens, will be necessary before definite findings can be established.

A full report of this work will be published elsewhere.

The opinions expressed here are those of the authors themselves and are not necessarily those of the organizations represented.

EFFECT OF OXYGEN ON THE INACTIVATION OF TRYPSIN BY IONIZING RADIATION

By Prof. J. A. V. BUTLER, F.R.S., and Dr. A. B. ROBINS
Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), Fulham Road, London, S.W.3

A CONSIDERABLE number of discordant observations on the effect of oxygen on the sensitivity of enzymes to ionizing radiation is to be found in the literature. A recent extensive study of the inactivation of chymotrypsin[1] showed, somewhat unexpectedly, but in agreement with observations by Miss L. K. Mee[2], that in dilute aqueous solution the dose required to produce a given degree of inactivation was greater in the presence than in the absence of oxygen. In view of this it seemed desirable to examine the effect of oxygen on the sensitiveness of the solid enzyme, and it was found that in this case, with 15-MeV. electrons, oxygen had little effect.

In the case of a similar enzyme, trypsin, it has been reported[3] that with 2-MeV. electrons from a Van de Graaff generator, and with cobalt-60 γ-rays, the sensitiveness of the enzyme in the solid state is enhanced by oxygen by about 30 per cent. It therefore became necessary to examine further the behaviour of trypsin, to discover whether or not it behaves differently from chymotrypsin in this respect.

In the first place, experiments were carried out on dilute solutions, using techniques similar to those previously described[1]. Using 140-kV. X-rays, it was found that the degree of inactivation by a given dose was increased *in vacuo* by a factor of about 4 (Fig. 1). In the case of the solid enzyme, several series of experiments were performed, using different methods of preparing the solid phase. For accidental reasons, different sources of high-energy radiation had to be used in the various series. The results of these experiments are shown in Fig. 2. The experimental conditions are as follows:

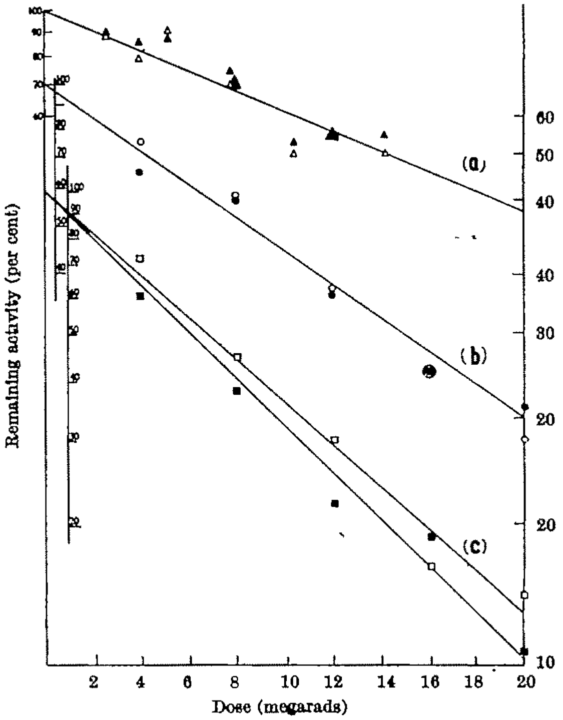

Fig. 2. Inactivation of solid trypsin by high-voltage electrons (conditions as in text). In oxygen: (*a*) △; (*b*) ○; (*c*) □. *In vacuo*: (*a*) ▲; (*b*) ●; (*c*) ■

(*a*) Trypsin films made by pumping off the water from a 1 per cent suspension of crystalline trypsin, supplied by the Worthington Biochemical Co. After the initial stage of evaporation, the liquid froze and the remaining water was pumped off. Irradiations were performed in either the 15-MeV. linear accelerator (300 rads per pulse of 1·3 × 10^{-6} sec.) at St. Bartholomew's Hospital Medical College, or the 4-MeV. (3 rads per pulse of 1·5 × 10^{-6} sec.) linear accelerator at the Mullard Research Laboratories, Salfords, Surrey.

(*b*) Crystalline trypsin in the form of a fine powder, as supplied by Worthington Biochemical Co. Irradiations carried out in the 4-MeV. linear accelerator (30 rads per pulse of 2·5 × 10^{-6} sec.) at the Wantage Radiation Laboratory of the Atomic Energy Research Establishment.

(*c*) Trypsin films made by dissolving the same trypsin in 10^{-3} *N* hydrochloric acid, freezing and pumping off the water. Irradiations as (*b*).

In all cases, when the enzyme was dry, the tubes were either sealed off *in vacuo*, after two flushings with argon, followed by evacuation to 0·05 mm. mercury pressure, or filled with oxygen and sealed. Enzyme activity was measured by Kunitz's casein method, as previously described[1].

The tubes were irradiated in pairs side by side, one evacuated and the

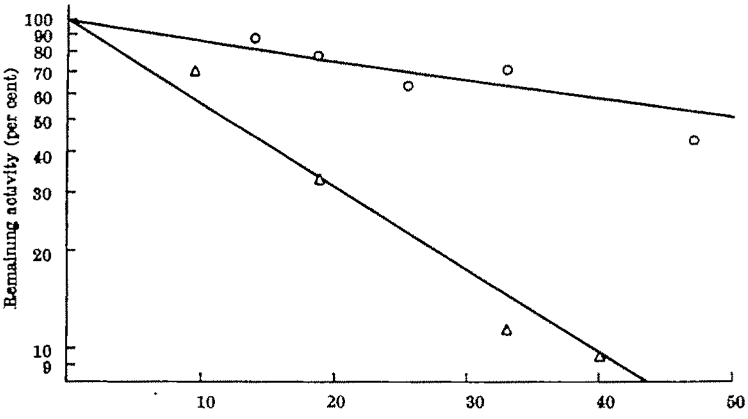

Fig. 1. Inactivation of trypsin in solution (0·028 per cent) by 140-kV. X-rays. ○, In air; △, *in vacuo*

other containing oxygen. It can be seen that in only 2 cases out of 17 did oxygen appear to increase appreciably the degree of inactivation as compared with the similar exposure *in vacuo*. (In some of the cases of series (*a*) the dosimetry appears to have been erratic, but this does not affect the conclusion stated.) In series (*c*) oxygen in fact decreased the inactivation to the extent of about 10 per cent.

It will be observed that the sensitiveness of the solid enzyme to irradiation is markedly modified by the mode of preparation in the solid film. Table 1 shows the mean values of D_{37} under the different conditions :

Table 1

Mode of preparation	D_{37} (megarads) In oxygen	 *In vacuo*
a. Film from aqueous suspension	20	20
b. Crystalline powder	11·8	11·8
c. Film from 10^{-3} *N* hydrochloric acid	9·8	8·8
d. Film with 25 per cent cysteine-hydrochloride	17·4	38

It is not clear whether these differences of sensitivity are due to changes in the state of the trypsin molecule, when treated in different ways, or to some modification of other substances present in small quantities. The initial activity of the enzyme was unaffected by these treatments. An experiment was performed to see the effect of a protective substance, cysteine, on the sensitiveness of the solid. Added in relatively large amount to the solutions of trypsin before evaporation, cysteine hydrochloride (weight ratio, cysteine hydrochloride/trypsin = 0·25) reduced the sensitiveness by a factor of 4 *in vacuo* and by only 2 in the presence of oxygen. It is therefore possible that the enhancements of sensitiveness by oxygen which have been reported were due to it reducing the degree of protection by a protective agent present.

These and the previous experiments show that, in aqueous solution at least, oxygen is capable of acting as a protective agent. Various explanations of this can be suggested ; for example, in the presence of oxygen, the primary H radicals will be replaced at least to some extent by O_2H. It is possible that O_2H is less effective than H in causing inactivation because it may react preferentially on the protein at points remote from the active enzyme centre. The effect of oxygen might therefore be to change the nature of the reaction from denaturation, which has been demonstrated in aqueous solutions[1], to a relatively innocuous oxidation. In the solid there does not seem to be any reason for expecting a similar situation. Alternatively, it is possible that oxygen, on account of its 'radical' nature, might be able to draw off the unbalanced charges present within the protein and thus localize the damage caused by them.

We are much indebted to Prof. J. Rotblat, St. Bartholomew's Hospital Medical College, London, to Messrs. T. R. Chippendale and D. R. Perry, Mullard Research Laboratory, Salfords, Surrey, and to Dr. R. Roberts and Mr. J. McCann, Atomic Energy Research Establishments, Wantage, for arranging the irradiations and for help in dosimetry.

This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research : Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

DISTRIBUTION AND PREVALENCE OF *FUSARIUM MONILIFORME* SHELD. (*GIBBERELLA FUJIKUROI* (SAW.) WR.) PRODUCING SUBSTANCES WITH GIBBERELLIN-LIKE BIOLOGICAL PROPERTIES

By PROF. W. L. GORDON

Plant Pathology Laboratory, Canada Department of Agriculture Research Station, Winnipeg

THE fungus *Fusarium moniliforme* Sheld. (*Gibberella fujikuroi* (Saw.) Wr.) is now generally recognized as the cause of the 'bakanæ' disease of rice (*Oryza sativa* L.) which has long been known to occur in Japan. The most characteristic symptom exhibited by diseased plants is a marked increase in height. In recent years this type of disease in rice has been reported from several other countries[1].

Kurosawa[2] first demonstrated, in 1926, that sterile filtrates of the 'bakanæ' fungus contained an active principle or growth stimulant which could cause a marked stimulation of growth in rice seedlings. Nine years later, Yabuta[3] announced that the active principle had been isolated. He gave it the name 'gibberellin' after the name of the perfect stage *Gibberella fujikuroi* (Saw.) Wr. of the 'bakanæ' fungus.

F. moniliforme Sheld. is widely distributed geographically, particularly on graminaceous plants. However, relatively few investigations have been carried out to determine if isolates of this fungus from hosts other than rice produce substances with gibberellin-like biological properties, which will be referred to in this article as 'gibberellins'. The results of the investigations published at the present time indicate that isolates of this fungus from hosts other than rice usually lack gibberellins, but occasional exceptions have been encountered. The detection of an isolate of *F. moniliforme* Sheld. possessing growth-stimulating properties has been reported by Nisikado[4], by Bugnicourt[5] and by Borrow, Bryan *et al.*[6] from sugar cane (*Saccharum officinarum* L.) ; by Nisikado and Miyawaki[7] from cotton (*Gossypium* sp.) ; and by Bugnicourt[5] from maize (*Zea mays* L.). The present investigation was undertaken to obtain additional information on the geographical distribution and prevalence of strains of *F. moniliforme* Sheld. producing gibberellins.

One hundred and five isolates of *F. moniliforme* Sheld. were included in this investigation. Of these isolates, eighty-four were classified as *F. moniliforme* Sheld., seventeen as the variety *subglutinans* Wr.

and Rg., and four as the variety *anthophilum* (A. Br.), Wr. Most of these isolates were received through the Commonwealth Mycological Institute, Kew, England; the others were received directly from research workers located in various geographical areas. The various isolates were received from time to time over the past twenty-five years. They were originally isolated from a total of thirty-five species of plants, one insect species, and from five miscellaneous substrates. They originated in twenty-nine geographical areas (Table 1).

The host plant employed for the detection of 'gibberellins' was the simple recessive mutant of *Zea mays* L., designated 'dwarf-1'. According to Phinney, West *et al.*[8] the qualitative responses of the mutant 'dwarf-1', in the seedling stage to gibberellic acid, to gibberellin A_1, and to gibberellin A_3 are similar. Seed of the mutant 'dwarf-1' was obtained through the courtesy of Dr. Bernard O. Phinney, Department of Botany, University of California, Los Angeles, California.

Before the various isolates were tested, each was established as a monosporous culture on potato sucrose agar (2 per cent agar, 2 per cent sucrose) slanted in 'Pyrex' test-tubes. Each test-tube measured 20 × 150 mm. and contained 10 ml. of the medium. The monosporous cultures were allowed to grow at least 10 days before they were employed in tests.

The various isolates were tested for 'gibberellins' by the following method. Two drops of the detergent 'Tween-20' were added to 100 ml. of sterile distilled water. 5 ml. of this solution were added to each monosporous culture. After 2 hr. the solution was decanted off into a 'Pyrex' glass vial and applied to seedlings of the 'dwarf-1' mutant with a medicine dropper. A few drops of the solution were applied in the axils of the first two seedling leaves. The seedlings were treated in this way twice a day for two days, and then were allowed to grow a further three days before final observations and measurements were made. Four seedlings were treated with the solution from each culture in each test. Seedlings were grown in flats kept on a window ledge in the laboratory in which the variation of temperature was 24°–30° C.

The growth response of seedlings treated with the extracts obtained from each of the various isolates was determined by measuring the distance from the apex of the coleoptile to the ligule of the second seedling leaf, to the nearest millimetre. The average of the measurements made on the four seedlings treated with the extract of a single isolate was compared with that of four untreated seedlings (treated with sterile distilled water with 'Tween-20' added at the level mentioned previously). The average growth response to the extracts of the various isolates tested was found to range from 0 to approximately 500 per cent greater than that of the untreated seedlings. Those isolates designated in Table 1 as being 'active' produced a growth increase more than 25 per cent greater than that attained by untreated seedlings.

It will be observed from the results presented in Table 1 that an appreciable number of the isolates produced 'gibberellins'. Thirty-five of the 105 isolates tested were rated as 'active'. Of the 35 'active' isolates encountered, 23 were classified as *F. moniliforme* Sheld., 11 as the variety *subglutinans* Wr. and Rg., and 1 as the variety *anthophilum* (A. Br.)

* F.m. denotes *F. moniliforme* Sheld.; F.m s., the variety *subglutinans* Wr. and Rg.; F.m.a., the variety *anthophilum* (A. Br.) Wr.

Wr. Although the majority of the isolates tested gave no indication of producing 'gibberellins', a sufficiently large number of 'active' strains was obtained to demonstrate that they are present in widely scattered geographical areas, and may be encountered on a range of host plants and on other substrates. Whether strains possessing 'gibberellins' originated in one geographical area, for example, Japan, or in various areas from time to time, several factors may have influenced their dissemination. One factor that would undoubtedly play an important part in their distribution would be seed-transmission. *F. moniliforme* Sheld. can be transmitted by seed, both internally and externally on the seed surface. The introduction of infested seed into areas where *F. moniliforme* Sheld. had not occurred would provide a rapid and effective means of dissemination of the fungus, and might also serve to introduce strains capable of producing 'gibberellins'.

The results obtained from the present investigation have provided information additional to that previously reported in the literature on the host-range and geographical distribution of strains of *F. moniliforme* Sheld. which produce 'gibberellins'. It appears likely to me that if investigations are carried on in the future along this line 'active' strains of *F. moniliforme* Sheld. will be demonstrated to be even more prevalent and widespread than the results of this investigation have indicated.

LOWER TERTIARY MICROFOSSILS FROM McMURDO SOUND, ANTARCTICA

By DR. LUCY M. CRANWELL (MRS. WATSON SMITH)
c/o Geochronology Laboratories, University of Arizona, Tucson

DR. H. J. HARRINGTON
Department of Geology, University of New England, Armidale, New South Wales

AND

I. G. SPEDEN
New Zealand Geological Survey, Lower Hutt

AN understanding of the climatic, biological and geological histories of Antarctica is important to many studies, such as those on the origin and dispersal of the floras and faunas of the southern hemisphere, on Quaternary glaciations, and on continental drift and polar wandering. Contributions have been made in reports on the Cretaceous and Tertiary sediments and fossils of the Graham Land region[1], the latest being by Cranwell[2]; but except for those reports there has been a considerable hiatus in our knowledge for the reason why Cretaceous and Tertiary fossiliferous sedimentary rocks have not been found in other parts of the Antarctic. This article records the finding of apparently Lower Tertiary sediments in the McMurdo Sound district of the Ross Sea region. The sediments are rich in microfossils, many of which have not been found previously in regions south of Australasia.

Structural considerations suggested to geologists of the New Zealand Geological and Survey Antarctic Expedition, 1958–59, that Cretaceous and Tertiary sedimentary rocks, similar to those of other circum-Pacific lands, could be expected to occur beneath the floor of the Ross Sea, and beneath the ice-sheet covering the greater part of Marie Byrd Land. It was plain that if rocks of those ages occurred they would not be accessible to direct geological observation, being hidden beneath the sea and ice, but it was considered that fragments of them might have been carried by ice to moraines in the McMurdo Sound region and to sea-floor deposits in the Ross Sea. Cretaceous or Tertiary sediments had not been found in the moraines by geologists of the Scott and Shackleton expeditions early in this century, but new searches were made at several localities. At Minna Bluff and White Island, Harrington and Speden, working independently, found in the moraines fragments of light-coloured fine-grained calcareous sediments which were immediately compared with certain distinctive sediments deposited in New Zealand during a marine transgression which occurred between the Late Cretaceous and the Oligocene[3,4]. They particularly resemble some units of a widespread calcareous mudstone facies, of which representatives are the Burnside Mudstone and parts of the Amuri Limestone[5]; and it is very doubtful if they would have been considered significant, or even noticed, but for this resemblance. The collectors naturally considered, therefore, and with considerable confidence, that their samples would be about Late Cretaceous or Lower Tertiary in age, and probably in the Upper Eocene–Oligocene part of that range, but others were sceptical and considered that they could have been derived from some of the finer-grained beds of the Upper Palæozoic and Lower Mesozoic Beacon Sandstone Formation[6,7]. Some specimens contain minute shell fragments, and one contains a fragment identified by Speden as part of a worm tube (? *Rotularia* sp.), which is not of value in age-determination (specimen *MS* 29, 7505*A*, New Zealand Geological Survey collections).

Afterwards, Mr. G. H. Scott, New Zealand Geological Survey, identified poorly preserved Foraminifera representing four genera in 7505*A*, a light-grey sandy mudstone from Minna Bluff. He states that "little can be said with confidence about the age of

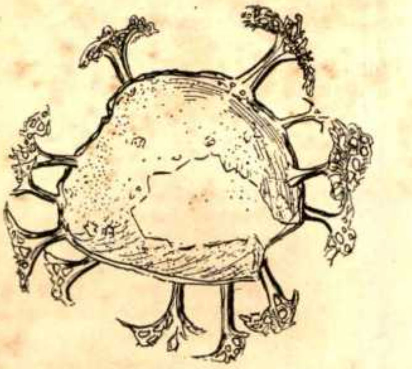

Fig. 1. *Hystrichosphaeridium* sp. from a mudstone fragment in a Minna Bluff moraine. Diameter, including appendages, about 100μ. This form has strong affinities with the *H. complex* group

the sample. In New Zealand *Angulogerina* of the type found in it does not occur prior to the Whaingaroan (Lower Oligocene); elsewhere the genus has Eocene representatives of the type discussed here, for example, *multicostata* Berquist from the American Jackson Formation, but Paleocene representatives seem to be lacking. It is probably correct to regard the *Angulogerina* of this fauna as indicating a post-Paleocene age. The occurrence of *Globoquadrina*, if correctly identified, would reinforce this age assignment, as this genus first appears in the Oligocene in New Zealand (Waitakian) and Australia".

The results obtained by Mr. Scott were not conclusive, but strongly supported the opinion held by Harrington and Speden, on lithological evidence, that the specimens are younger than Upper Palæozoic or Lower Mesozoic, and close to Eocene or Oligocene in age.

Fragments of specimens 7505 and 7505*A* were sent to Cranwell, and a small pollen component was recovered along with a wealth of hystrichosphaerid (Fig. 1) and dinoflagellate forms. Further study will be needed before adequate comparison can be made with the Australian and New Guinea microplankton described since 1953 in the pioneer researches of Cookson, Deflandre and Eisenack[8-11], and correlated by them, in some cases, with European finds in particular. At present it appears that faunal and floral elements point to some Cretaceous, or earlier, admixture, but much of this may be traced to redeposition, or to misinterpretation caused by our lack of knowledge of the time-range of hystrichosphaerids recorded solely, or with few exceptions, from the Cretaceous or earlier. Only in 1958 did Cookson and Eisenack begin to report Tertiary occurrences for some of these key Mesozoic forms.

The pollen grains are few in number but well preserved, though tending to stain lightly; they belong to groups already known at Seymour Island[3] from macrofossil and microfossil remains; but none of the types so far recognized is identical. No fern spores, no fungi, no cuticles and only a few tracheids (single broken shreds) were found. Species of southern beech (*Nothofagus*) predominate (Fig. 2), and there are ties, on one hand, with New Guinea, Australia, New Caledonia and New Zealand forms, either fossil or living, and on the other, a link, stronger than in the Seymour Island material, with certain characteristic South American forms. The conifers occur in lower frequencies and their types have not yet been sorted out to our satisfaction. Palmoid and proteaceous types occur, and a few others have been noted. The microplankton contains plani-spiral microforaminifera, and there are a few fragments which suggest alcyonarian spicules.

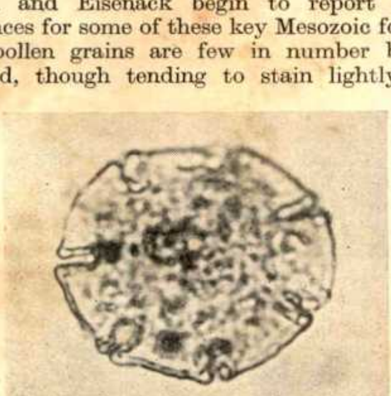

Fig. 2. Pollen-grain of *Nothofagus* sp. from a mudstone fragment in a Minna Bluff moraine. Diameter about 26μ

Dating of the pollen cannot yet be fixed: it is not likely to have originated earlier than the mid-Cretaceous, judging by work done in New Zealand by Couper[12], and it is probably not as recent as the Miocene cooling in the Graham Land region described by Adie[1]. As in the Seymour Island material, the pollen absences (for example, Compositae) might be taken to eliminate Miocene possibilities, but it must be remembered that the assemblage can only be a weak representative of the original communities since large grains, and insect-pollinated types, are less fitted to travel great distances in air currents, and we have here no suggestion of carriage by muddy rivers. The total evidence, of course, tends to indicate an age between the Late Cretaceous and the Oligocene, as indicated by the lithology, and the Foraminifera recorded by Mr. Scott.

The low frequencies—only a few grains per slide—and the restriction to small wind-pollinated types (mainly less than 35μ), coupled with the wealth of hystrichosphaerid and dinoflagellate remains, strongly indicate settling in offshore waters of normal salinity and low turbidity (cf. Orinoco Delta deposits described by Muller[13]) and at some distance from the land areas where temperate forests yielded the pollen rain. These conditions could well be matched during a marine transgression across a shallow continental shelf bordering a low, easily flooded land-mass, or by the existence of shallow marine troughs between island groups in a time of base-levelling and relative tectonic calm. It is conceivable, by comparison with New Zealand and other circum-Pacific lands, that island groups and marine troughs existed that were precursors of the ridges and depressions discovered buried beneath the ice of the Ross Sea–Weddell Sea region, as the result of a magnificent series of traverses by United States seismic-sounding parties[14].

In addition to the notes already given, we wish to stress that these are the first records, so far as we can ascertain, of dinoflagellates, hystrichosphaerids, microforaminifera, scolecodonts (annelid jaws: very rare), ? alcyonarian spicules, pollen, tracheids and spores (undetermined) from this area, and the first fossil occurrences of several of these groups south of Australasia.

Thanks are extended to the United States Navy for transport to Antarctica and localities in the Ross Sea region; to Messrs. A. C. Beck, E. B. Fitzgerald and other members of the expedition for co-operation in the field work under arduous conditions and for sharing notes and views; to Mr. G. H. Scott, New Zealand Geological Survey, for his work on the Foraminifera; and to Prof. Terah Smiley and his staff at the Geochronology Laboratories, University

of Arizona, and particularly to Mr. Bernard C. Arms for running our unpromising samples by a new silica depressant method[15].

AGE OF EMPLACEMENT OF GRANITES

By Dr. W. COMPSTON, Dr. P. M. JEFFERY and G. H. RILEY

Department of Physics, University of Western Australia, Nedlands, Western Australia

RADIOACTIVE age determinations are usually made on the separated mineral components of a rock rather than on the whole rock itself, and the age of emplacement of the latter, regarded as the time at which the various radioactive elements first became fixed into different mineral species, is then inferred from the ages of the minerals. This procedure is valid only when at least one of the minerals has remained a closed chemical system since first crystallization. As there is no independent means of recognizing a closed system, it becomes necessary in practice that the ages of all constituent minerals should agree before much confidence can be placed in any inferred age of emplacement. Even with this stipulation, the result is not conclusive, since it will also be met by the minerals of a completely recrystallized rock.

Several instances[1,2] have been reported in metamorphosed granitic rocks in which biotite yields a lower rubidium–strontium age than microcline, and each mineral in addition possesses different potassium–argon and rubidium–strontium ages; one case[3] was recently cited of a microcline which lost radiogenic strontium during metamorphism. The age of rock emplacement in such cases becomes less and less founded on verifiable fact, and some alternative means of determining this age is most desirable.

The fact that in some cases mineral grains are evidently open chemical systems does not necessarily mean that the rock as a whole must also be an open system. This was considered by Schreiner[4], who found experimentally that 'total rock' ages by the rubidium–strontium method were in reasonable agreement with pure mineral ages for the red granite of the Bushveld Complex. We have recently analysed total rock samples of a metamorphosed granite and associated pegmatites from Mundaring, Western Australia, in which pegmatitic muscovite and microcline were the only minerals to retain an old rubidium–strontium age. Although each total-rock sample was found to possess a different ratio of rubidium to strontium, they all gave the same age for a unique value of the ratio initial strontium-87/strontium-86, which was also the age given by the muscovite. We believe that this figure is the age of emplacement of the granite, and that total-rock analysis represents both the simplest and least ambiguous method of determining this age.

Analytical results for five total-rock and four mineral samples are listed in Table 1. The quantities directly measured for each sample are the present-day ratio strontium-87/strontium-86, using an unspiked aliquot of the sample in solution, and the ratio rubidium-87/strontium-86 by isotope dilution using other aliquots. (We find that calculation of the ratio strontium-87/strontium-86 from spiked strontium data is unreliable for samples rich in common strontium, due to variability in the ratio strontium-88/strontium-86 in the sample, and to enhanced magnification of mass-spectrometric random errors.) From the expression:

$$\text{Age} \simeq \frac{^{87}\text{Sr}^*}{\lambda\,^{87}\text{Rb}} = \frac{^{86}\text{Sr}}{\lambda\,^{87}\text{Rb}}\left[\left(\frac{^{87}\text{Sr}}{^{86}\text{Sr}}\right)_{\text{present}} - \left(\frac{^{87}\text{Sr}}{^{86}\text{Sr}}\right)_{\text{initial}}\right]$$

where $^{87}\text{Sr}^*$ denotes radiogenic strontium and λ the decay constant of rubidium-87, it may be seen that the ratio $\lambda\,^{87}\text{Rb}/^{86}\text{Sr}$ has been the time-rate of change (approximately) in the ratio $^{87}\text{Sr}/^{86}\text{Sr}$ of the sample for whatever period it has remained a closed chemical system. The term $(^{87}\text{Sr}/^{86}\text{Sr})_{\text{initial}}$ denotes the ratio for the system at the time it was generated: it constitutes in fact another unknown quantity besides age in the rubidium–strontium method. Mathematically, however, we may at first avoid attaching physical significance to this term by regarding it as the independent variable in an equation

Table 1

Mineral Data and Ages

	Rubidium (p.p.m.)	Common strontium (p.p.m.)	Radiogenic strontium (p.p.m.)	Age (m.yr.)
Muscovite from pegmatite	1,834	5·8	19·8	2,700
,, ,,	2,163	5·3	23·2	2,690
Microcline from pegmatite	1,125	27·8	10·3	2,300
Biotite from pegmatite	1,309	6·5	3·43	670
Micromuscovite from granite	501	144	5·48*	2,730

* Based on a strontium-87/strontium-86 ratio initially 0·70. Ages calculated using rubidium-87 decay constant of $1·386 \times 10^{-11}$ yr.$^{-1}$.

Total-rock Data

	Rubidium (p.p.m.)	Total strontium (p.p.m.)	^{86}Sr/^{87}Rb	^{87}Sr/^{86}Sr
Granite 1	165·5	129	0·266	0·842
Granite 2	186	129	0·236	0·864
Granite 3	226	106	0·157	0·945
Biotite–pegmatite	194	71	0·122	1·010
Muscovite–pegmatite	331	21·4	0·018	2·85

for age. The straight lines as given by the above expression have been plotted for each sample in Fig. 1. They converge very distinctly to the region:

$$^{87}Sr^*/^{87}Rb = 0{\cdot}0383\ ;\quad ^{87}Sr/^{86}Sr = 0{\cdot}700$$

On the assumption that the strontium throughout this granite was initially uniform in isotopic composition, it may be inferred now that: (i) each total rock sample has indeed remained a closed system with respect to rubidium and strontium back to the point in time defined by these co-ordinates; (ii) the variable ratio of strontium to rubidium is due to an initial inhomogeneity in the granite; and either (*iiia*) the age corresponding to this point, 2,700 m.yr., is the age of emplacement of the granite, or (*iiib*) 2,700 m.yr. is the age at which all earlier formed radiogenic strontium in the system diffused out from the rubidium-rich minerals and became completely mixed with common strontium throughout the granite. In either case, the ratio strontium-87/strontium-86 of the system at this time was 0·700 throughout.

The alternatives in inference (iii) simply represent the fundamental ambiguity in radioactive age determinations mentioned initially, which is present even in a rock, the minerals of which all give the same age as the whole-rock samples. However, in the future it may be possible to eliminate one of these alternatives by considering the absolute value of the ratio strontium-87/strontium-86 at the point of concurrence. Meteoritic strontium, the strontium-87/strontium-86 ratio of which is about 0·685 (ref. 5) presumably represents the source from which the present-day common strontium of the crust evolved. If the value of the latter is approximately 0·715 (a little greater than the average present-day ratio in basic igneous rocks as measured in this laboratory), and if its evolution has been approximately linear with respect to time, then a granite formed from average crustal strontium 2,700 m.yr. ago should possess an initial strontium-87/strontium-86 ratio of about 0·700. This in fact is the value found above, so that the granite total-rock age could be interpreted on this picture specifically as the age of emplacement. However, the assumptions concerning the sampling and evolution of crustal strontium, though reasonable, have not yet been substantiated experimentally.

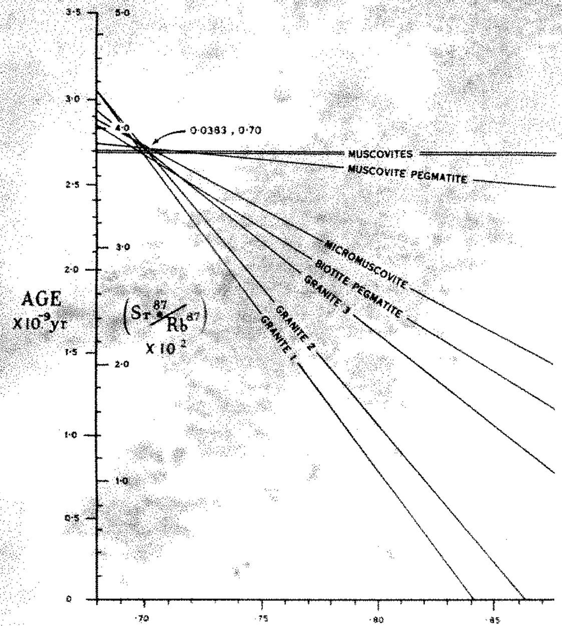

Fig. 1

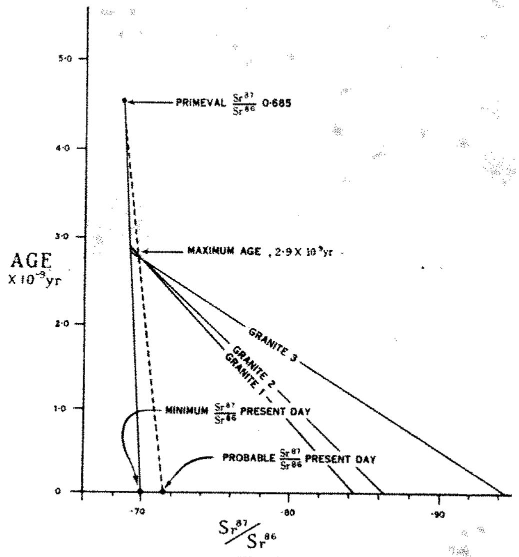

Fig. 2

In any event, it is possible still to set an upper limit to the age of the granite, if it was formed directly or indirectly by some process of differentiation from mantle material. Taking 0·700 as the value of the ratio strontium-87/strontium-86 for the present-day mantle, and again assuming a linear evolution of this ratio from primeval strontium, then the maximum age of the granite becomes 2,900 m.yr. (Fig. 2). Even in the most unlikely case that essentially primeval strontium was incorporated with the granite, its age still could be no greater than about 3,000 m.yr.

One further result follows if 2,700 m.yr. is taken as the age of emplacement of the granite. Fig. 1 shows that the pegmatites also have this age, thereby confirming the widely held premise that pegmatites can form immediately on the solidification of a granite.

Finally, as regards the ages of the mineral, we wish to emphasize that none of the potassium feldspars from these granitic rocks exhibits complete preservation of the 2,700 m.yr. event. Pegmatitic microcline comes closest at 2,300 m.yr., whereas granitic microclines show any 'age' down to about 650 m.yr., which is also the age registered by all biotites. Pegmatitic muscovite and micromuscovite, formed in the granite during saussuritization of the plagioclase feldspar, alone show complete retention. The latter shows, incidentally, that saussuritization was definitely a late-stage magmatic process in this case.

Full details of these age determinations will be reported elsewhere. We are grateful to Dr. A. F. Wilson and Mr. I. Martin, of the Department of Geology, for helpful discussion and practical assistance, and to the Research Grants Committee of the University of Western Australia for financial support.

LETTERS TO THE EDITORS

GEOPHYSICS

A Telemetered Seismic Net in Tasmania

Work during the past eighteen months towards the establishment of a telemetered seismic net in Tasmania has involved research in which electronics and seismology have been brought into close contact. Information about the net itself will be published in detail elsewhere, but the purpose of this communication is to describe new ideas which have arisen from contact between the two fields. The developments have followed two lines. First, the application of electronic amplifiers and the principles of feedback servomechanisms to the design and construction of seismographs. Secondly, and perhaps more important, has been the consideration of problems in observational seismology from the point of view of information theory as the problem of extracting a message from a noisy background. This, by analogy with other fields, has led to the consideration of methods whereby the discrimination of seismographs against background noise could be improved.

Our electronic seismograph uses a transducer with variable reluctance, but with an a.c. magnet; the output then consists of amplitude-modulated alternating current which is easy to amplify and telemeter. The response of the seismograph can be readily controlled by feeding back to the pendulum, in the correct proportion, the demodulated output of the amplifier together with its derivative and integral. For example, Fig. 1 shows the performance of conventional seismographs as given by Willmore[1], to which we have added for comparison the performance of our seismograph.

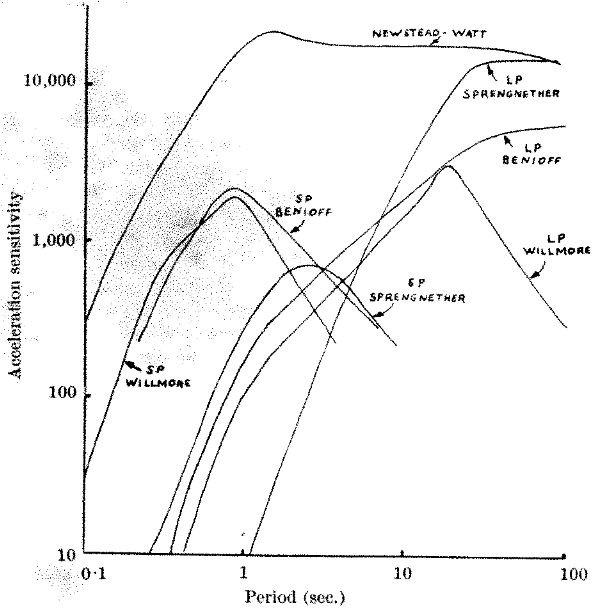

Fig. 1. Diagram showing performance of conventional seismographs given by Willmore (ref. 1) to which we have added for comparison the performance of the a.c. seismograph

With the particular combination of feedback used, it will be seen that it acts as an accelerometer between 1 and 100 sec., and its response is above the envelope of the performance shown for the conventional seismographs. Now that the performance is well under control, the question arises as to the best way to adjust it for various purposes. Seismologists have traditionally thought in terms of periods and damping, and various adjustments[2] are used for particular instruments, most of which are highly resonant. As shown, our seismograph has been adjusted as a broad-band accelerometer; this, however, is purely for comparison and it could equally well be adjusted in other ways. The problem of what characteristics it should in fact have to obtain optimum performance depends on the statistics of the signal and the message, and these have received only scant study by seismologists. For the present, therefore, we propose to record the whole of the information contained in the band and experiment with filtering and other processes on the record itself. Provided that external noise is the factor which limits the performance, this procedure will not affect the signal-to-noise ratio in the recorded information.

Willmore[3] has considered the limitation of sensitivity in seismographs which do not use amplifiers. If amplifiers are used, then the limitations he has discussed do not apply—the absolute level of sensitivity shown in Fig. 1 was arbitrarily chosen for the purpose of comparison, and it could be increased by several orders of magnitude if required. When sensitivity is not the limiting factor, the signal-to-noise ratio becomes apparent as the limit of resolution, and it is necessary to consider various noises. Seismologists do not appear to have adopted standard methods of specifying ground movements, although the displacement of the ground is often quoted in microns. Without a more complete knowledge of the spectrum, this is not very useful for comparing instruments which are to be used at other frequencies, and in what follows we shall mean the equivalent displacement of the ground in microns at 1 c./s., the figures given being orders of magnitude only. Background ground movement depends on the site and the particular day, and may range from 0·1 to 10 microns. In our seismograph, amplifier noise corresponds to a minimum detectable signal of 10^{-5} micron. This should be increased by an unknown amount to take account of Barkhausen noise in the transducer. We have not been able to estimate the amount of this noise, but indications are that it is very small. There remains finally the ultimate limit of seismometry—the Brownian motion of the pendulum—which we roughly estimate for our seismograph to correspond to a signal of less than 10^{-5} micron.

At present, background noise predominates; but preliminary experiments conducted in Hobart suggest that noise recorded at sites separated by a few miles is largely uncorrelated. If this is so, it will be possible to resolve discrete signals out of the background by measuring the correlation between signals received at different sites. This idea was developed for radio astronomy, and although the techniques are more difficult in the seismic case they are still possible. We are designing and propose to construct a correlation machine to measure in pairs the correlation between the records of the various stations in our net.

Initially we are using pen-and-ink recording on paper; however, we are working simultaneously on an arrangement using magnetic recording on tape with electronic reduction of the information. The magnetic recording will be done at tape speeds of ¼ in. per sec. and replayed at much higher speeds. This will reduce the time of interpreting the records, and by raising the significant frequencies will make filtering and other analogue operations on these signals much easier. For example, it will be possible immediately to obtain the spectra of various natural and artificial seismic events from the tape recordings, and also to produce records from the broad-band recordings identical with those which would have been produced by highly resonant seismographs located in the band. Eventually, it will be possible to produce tapes which can be fed into digital computers for processing in various ways.

We wish to acknowledge the help provided by Prof. S. Warren Carey, professor of geology in the University of Tasmania, who initiated the idea ofthe telemetered net and who has also provided many helpful discussions and ideas.

METEOROLOGY

Sodium/Potassium Ratio in Rain-water

DR. B. C. V. ODDIE has commented[1] on a portion of my recent article "Surface of the Ocean as a Source of Air-Borne Nitrogenous Material and Other Plant Nutrients"[2] with particular reference to the sodium/potassium ratio in rain-water. In this article I presented results of the analysis of New Zealand snows and proposed that there exists on the surface of the ocean a very thin layer which is rich in potassium, nitrogenous material and other substances as a result of the activities of micro-organisms. It was suggested that portions of this layer are transferred to the atmosphere by the bursting of bubbles in 'white caps' and thence to the land. I referred to the fact that the sodium/potassium ratio in rain is often markedly lower than that in bulk sea-water and suggested that the excess potassium was coming from the surface layer described above. Oddie directs attention to the fact that the low sodium/potassium ratios commonly recorded at inland collecting stations are scarcely ever observed at exposed coastal stations in Europe and North America and states that in general the more maritime the situation of a station the more closely does the ratio approximate to that of sea-water (that is, 27). He makes reference to results from the Shetland Islands. Oddie further states, however, that this is evidence against my suggestion, at least for European and American rains.

Table 1. SODIUM/POTASSIUM RATIOS OF COASTAL NEW ZEALAND SNOWS

	Distance from sea (miles)	Sodium (p.p.m.)	Potassium (p.p.m.)	Sodium/potassium
Snow collected May 3, 1958, on Mt. Egmont at 6,000 ft.	20	0·68	0·24	2·8
Snow collected April 27, 1958, on Tasman Glacier at 7,000 ft.	25	0·20	0·18	1·1
Snow collected August 22, 1958, at Temple Basin, Arthurs Pass, at 5,000 ft.	30	0·04	0·02	2
Sea-water		11,000	410	27

In the case of snows (Table 1) collected close to the sea on the west coast mountains of New Zealand the potassium must come from the ocean as there is no industry or for that matter land to act as its origin. In the case of the European and North American rains the problem perhaps is complicated by fuel combustion, industry, etc., and it is not possible for me to say how much of the excess potassium comes from the ocean or from other sources. However, Oddie is scarcely justified in ruling out my hypothetical mechanism as a source of some of the excess potassium in European rains on the evidence that the sodium/potassium ratio approaches 27 as one approaches an exposed coast. In such considerations one must rather consider the total amount of potassium deposited each year. To illustrate this, let us take Oddie's own example of Sweden[3]. The yearly integrated sodium/potassium ratio decreases from 10 on the coast to 1·7 at 200 km. from the sea. If instead the potassium deposited per annum is taken it is seen to be[3] 3·8 kgm./har. on the coast dropping to 2·4 kgm./har. 200 km. inland. The high sodium/potassium ratios on the coast are caused not by low potassium deposition but by high sodium deposition due probably to wind-blown bulk sea-water. On the coast in New Zealand this can be very great (near Wellington airport (Rongotai), for example, 210 lb./acre/yr. of chlorine are deposited[4]); this will raise the sodium/potassium ratio toward that of bulk sea-water. This effect (as does the sodium/potassium ratio) drops off rapidly with distance, presumably due to the large size of the wind-blown sea-water drops. In my discussion of the snow analyses[2] I corrected for the "wind-blown sea-water effect" by considering only "the excess potassium" which was defined thus:

excess potassium ion concentration = potassium ion concentration − 1/27 sodium ion concentration

Nevertheless one can, as is seen from Table 1, obtain snow samples near the coast with sodium/potassium ratios as low as 1–3 which Oddie claims are only found at inland collecting stations. It should be noted, however, that these were all taken at high altitudes, and it is possible that the heavier wind-blown bulk sea-water salt does not reach these altitudes. Another point is that in collecting fresh snow one obtains the precipitations of only an hour or so, whereas if samples of rain-water are collected over relatively long periods (weeks) an integrated value is obtained. Thus any period of high wind will deposit wind-blown bulk sea-water and so raise the average sodium/potassium ratio of the rain. I would suggest that individual rain showers be collected over short periods of time (for example, ½ hr.) at the European coastal stations in question (for example, Lerwick). It seems probable that some of these (collected on days with no high wind) will give sodium/potassium ratios approaching those of inland stations.

PHYSICS

Velocity of Light in a Magnetic Field

One consequence of classical electromagnetic theory is that the velocity of light *in vacuo* should be unaffected by superposed magnetic or electric fields; this conclusion is worth checking experimentally whenever a sufficient advance occurs in precision of observation. As regards the constancy of the velocity of light through a vacuum in the presence of a transverse magnetic field, the most precise observations higherto made are probably those of Banwell and Farr[1]. These investigators showed in 1940 by an interferometric technique with photoelectric recording that in a field of 20,000 oersted the change of velocity, if it existed, was unlikely to be much more than an increase of about 30 cm./sec.; their probable error was about 18·6 cm./sec.

Recent developments[2] in the photoelectric detection of small deflexions of a beam of light have made it possible to look for deviations of such a beam when passing through a transverse magnetic field shaped to resemble an optical prism; this shape of field was first applied by Rabi[3] to improve the accuracy of the Stern–Gerlach technique.

The photoelectric detection system has a root-mean-square error of about $1{\cdot}4 \times 10^{-11}$ radian for a bandwidth of 1 cycle/sec.; it has been used to look for deviations of the light beam when a field of about 8,000 oersted is switched on and off for alternate 10-sec. periods. By taking 400 observations, giving a total observing time of about 8,000 sec., the error in comparing the directions of the light beam before and after passage through the prismatic field has been reduced to a root-mean-square value of $5{\cdot}5 \times 10^{-13}$ radian. The average change in direction actually found was $1{\cdot}8 \times 10^{-13}$ radian, away from the apex of the prism; since this was only about one-third of the root-mean-square error, we may conclude that no significant deflexion was observed. For nearly one-half of all the observations, unpolarized white light was used; in the remainder, the same light was plane polarized, with its electric vector first parallel to the magnetic lines of force, and afterwards at 45° to this direction.

The effective prism angle was about 100°; the angular root-mean-square uncertainty of $5{\cdot}5 \times 10^{-13}$ radian therefore corresponds to a root-mean-square uncertainty in the constancy of velocity (or of refractive index of the magnetic field) of about 2·3 parts in 10^{13}. Should the velocity of light be subject to a simple change by as much as 100 micron/sec. in a transverse field of 8,000 oersted, the change ought to have been detected.

While this negative result may have little consequence, the figures indicate that optical deflexion measurements by photoelectric methods can be comparable in precision with maser experiments[4] and Mossbauer techniques[5].

'Prize': a Pre-ionized 'Theta' Pinch

Work has recently begun here on an experiment designated 'Prize'.

'Prize' is an electromagnetic shock-tube using pre-ionization in the Z direction followed by a theta pinch; its main function is to form a high-temperature plasma in deuterium gas by shock heating[1] without the ubiquitous trapped magnetic field usually associated with theta pinches and described elsewhere[2,3].

In the conventional theta pinch the magnetic field is able to penetrate the cold gas before the initial formation of the current sheet. This trapped magnetic field reduces the temperature of the imploding shocked gas since work is done in compressing it; the field also gives rise to instabilities on the second half-cycle of the discharge[3]. In earlier experiments at Foulness other methods of eliminating trapped magnetic field were tried including the use of a d.c. bias magnetic field to cancel out the trapped field and also plasma injection using a Kolb type '*T*' tube. In 'Prize' a thin annular cylinder of high-conductivity plasma is formed by a linear pinch before the azimuthal currents in the theta piece set up a longitudinal magnetic field. The magnetic piston set up by the currents in the theta piece then drives the thin annular current sheet towards the axis of the shock tube and, due to the high conductivity of the initial pinch, the diffusion of magnetic field into the plasma is considerably reduced.

Figs. 1 and 2 show the geometry of 'Prize'. The linear Z pinch is set up between the annular electrodes at each end of the quartz tube; the 'backstrap' required to form the initial axial current discharge near the walls of the discharge tube, at the point of minimum inductance, is the thin slotted copper cylinder on the outside of the tube. The cylinder is,

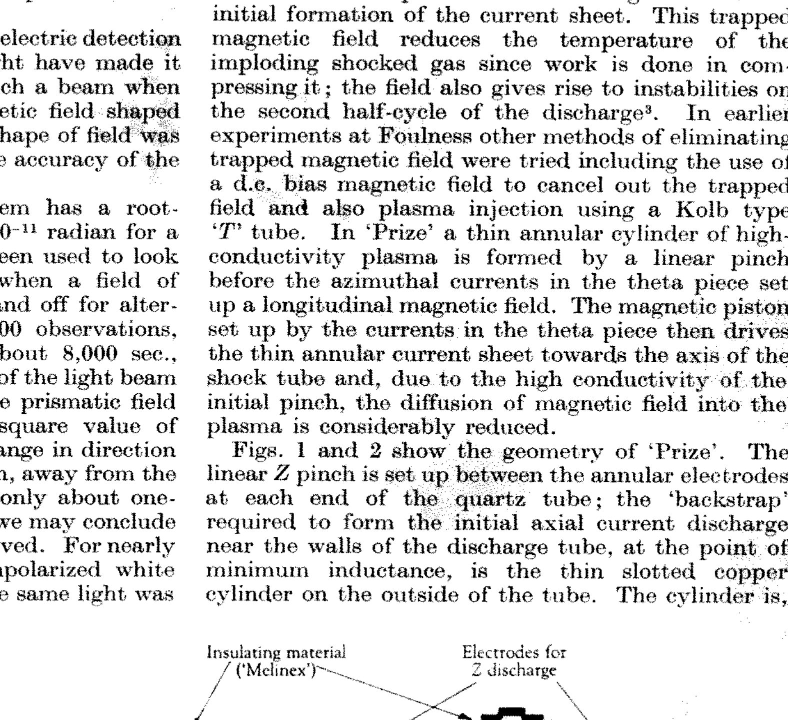

Fig. 1. Cross-section of 'Prize'

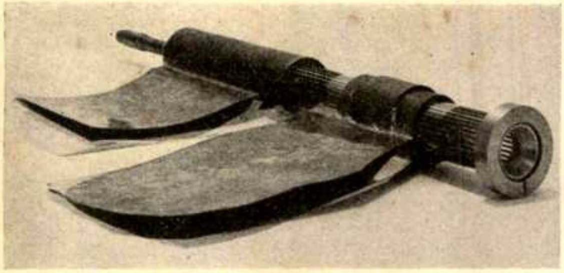

Fig. 2. 'Prize'

of course, slotted to allow the magnetic field set up by the theta piece to penetrate into the quartz tube.

Fig. 3 shows a schematic diagram of the circuitry associated with 'Prize'. Switching has been designed so that the linear pinch does not move appreciably before the theta voltage is applied. The switching arrangement is a simple but effective explosive sandwich layer consisting of three copper strips separated by 'Melinex', the order of the strips being, from top to bottom, Z live, common earth, theta live with the explosive uppermost. This ensures that the theta voltage is applied approximately 0·1 μsec. after the Z voltage.

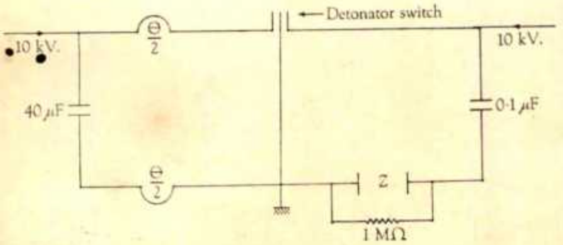

Fig. 3. Schematic diagram

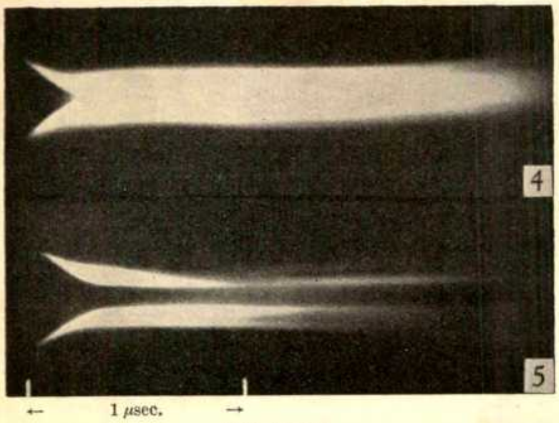
Our early experiments have been concerned with the synchronization of events, and for this purpose we have used convenient values of voltage, 10 kV., and stored energy, theta 2 kilojoules, Z pinch 5 joules, and a theta piece consisting of a single copper turn. Figs. 4 and 5 show streak camera records (radius time curves) of the motion of the shock fronts for 'Prize' fired with and without the Z pre-ionization and an initial deuterium pressure of 1 mm. Fig. 4 shows no trapped magnetic field with a completely converging shock system on the first half-cycle of the theta discharge and Fig. 5 appreciable trapped magnetic field.



Figs. 4 and 5

We are now entering the second phase of the experiment in which we intend to apply more energy to a Scylla[4] type theta piece.

Ultra-High Resolution γ-Ray Resonance in Zinc-67

We wish to report the observation of nuclear resonance absorption (Mössbauer effect[1]) of the 93 keV., 9·4 μsec. γ-ray[2] of zinc-67. The energy width of this line is $4 \cdot 84 \times 10^{-11}$ eV., and the fractional energy resolution, defined as the ratio of twice the natural line width to the γ-ray energy, is 1 part in 10^{15}, and is 10^{3} fold narrower than that reported[3] for iron-57. By the same token, the resonance is difficult to observe, because it is easily destroyed by small-amplitude sound vibrations and broadened and weakened by nuclear electric quadruple interactions in the crystals[4].

A search for the resonance was made using a mechanically rigid package of absorber and source, suspended by threads inside a liquid-helium cryostat. The resonance condition was destroyed by applying an external magnetic field to the absorber but not the source, making use of the nuclear Zeeman effect.

A source of 78-hr. gallium-67 was prepared by deuteron bombardment of a ceramic zinc oxide slab. Gallium-67 decays by electron capture to excited states of zinc-67. Following annealing of the source in a helium atmosphere for 18 hr. at 366° C., the source and a ceramic zinc oxide absorber (thickness 5·6 gm./cm.^{2}) were placed in a shock-mounted helium cryostat. A solenoid surrounding the absorber provided a magnetic field. The source was mounted at a distance of 1·5 cm. from the absorber, and was shielded from the magnetic field by a superconducting lead foil. The experiments were performed at temperatures below the helium λ point, thereby eliminating boiling and assuring equality of source and absorber temperatures. Freezing the nitrogen radiation shield prevented vibrations due to boiling liquid.

Determinations were made of the increase in transmission of the 93-keV. gamma radiation through the zinc oxide absorber on application of a magnetic field to the absorber. A field of 150 oersted is expected to destroy the resonance condition completely, assuming no line broadening. With an applied field of 500 oersted the low-temperature transmission was found to increase by (0·080 ± 0·008) per cent over the zero field value. After correction for background in the γ-ray spectrum the transmission increase is (0·240 ± 0·025) per cent.

Control experiments were run at room temperature, where no resonance is expected, using the 93-keV.

γ-ray, and at low temperatures using a 184-keV. non-resonant γ-ray. An unannealed zinc oxide absorber was studied. Measurements were taken on annealed (14 hr. at 650° C.) and unannealed zinc spinel (zinc oxide–alumina). Because of difficulty in placing the active gallium atoms in the proper lattice positions in the spinel, no resonance was expected, and none was observed. The results of all our measurements are summarized in Table 1. The magnetic fields used were in all cases approximately 500 oersted. The only significantly non-zero resonance is found in the annealed zinc oxide at low temperatures.

Table 1

Material	Annealed	γ-Energy	Temperature (° K.)	Resonance (per cent)
ZnO	yes	93 keV.	$<2\cdot17$	$0\cdot080 \pm 0\cdot008$
ZnO	no	93	$<2\cdot17$	$-0\cdot06 \pm 0\cdot06$
ZnO	yes	93	300	$0\cdot005 \pm 0\cdot003$
ZnO	yes	184	$<2\cdot17$	$0\cdot02 \pm 0\cdot02$
Spinel	yes	93	$<2\cdot17$	$0\cdot016 \pm 0\cdot014$
Spinel	yes	93	300	$0\cdot02 \pm 0\cdot03$

Despite the minute resonance strength observed in zinc oxide, the ratio of the resonance strength to the energy resolution is larger than for any other resonance thus far reported (about three times larger than has been obtained with the 14-keV. line in iron-57[3]), and hence the 93-keV. γ-ray of zinc-67 provides the possibility for the most precise nuclear clock available. We are at present attempting to enhance the observable resonance through the utilization of resonant scattering methods, and are studying the isotope shift expected when the isotopic constitutions of source and absorber are different.

We wish to express our thanks to Stephen Stoddard and Robert Cowan for preparing the zinc oxide samples, to Donald R. F. Cochran for help with irradiations, and to J. G. Dash for a number of helpful discussions.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

Mass of Elementary Particles

PROF. A. J. RUTGERS in *Nature* of September 19, 1959, and Dr. R. L. Worrall in *Nature* of February 27, 1960, pointed out that the ratio of proton to electron mass could be calculated from simple functions. It appears that the masses of most elementary particles can be calculated, approximately, using three quantities, h, Planck's constant, a, the fine structure constant, and e, the base of the natural logarithms. The calculated values obtained are in good agreement with the known values.

Worrall suggests the following equation for calculating the mass of the proton:

$$M_p = \text{mass proton} = (10^4/2e)\ M_e$$

where M_e is the mass of the electron. Since $e^2 \sim 10^3 a$, it is possible that the fine structure constant is involved. $M_p \sim (5e/a)\ M_e$.

Meson masses can be calculated in the following way:

$$\begin{array}{lll} \text{Mu meson}: 1/e\ (4/a)\ M_e & \sim & 202\ M_e \\ \pi \text{ meson}: (2/a)\ M_e & \sim & 274\ M_e \\ K \text{ meson}: (7/a)\ M_e & \sim & 959\ M_e \\ \text{Hyperon}: (7/5)\ M_p & \sim & 2{,}585\ M_e \end{array}$$

The observed masses are almost exactly equal to the calculated masses.

The hyperons may have the following structure:

$$\begin{array}{lll} 1{,}840 + 959/e + 959/e & \sim & 2{,}545\ M_e \\ 1{,}840 + 959/e + 274/e & \sim & 2{,}295\ M_e \\ 1{,}840 + 959/e & \sim & 2{,}190\ M_e \end{array}$$

Since a binding energy may also be present, these calculated values are not unreasonable. However, if they are correct the factor e appears to be important. There is a mass decrease on particle formation through action of the factor $1/e$ as suggested by Worrall. However, the factor could be $1/(10^3 a)^{1/2}$.

The electron mass can be expressed in terms of frequency and c^2 by the equation:

$$\begin{gathered} h/M_e = c^2/v \sim 7\cdot3 \text{ cm.}^2/\text{sec.} \\ 7\cdot3 \sim 10^3 a \sim e^2 \\ h/e^2 \sim 9 \times 10^{-28} \end{gathered}$$

There are now three nearly equal quantities involved in mass calculations. Meson masses can be expressed as follows:

$$\text{Mass of mu meson} = (1/e)\ 4\ h/a\ (c^2/v)$$

It seems reasonable to suppose there is some connexion between the three quantities in the above equation. The ultimate equation may involve only h/c^2, a conversion factor dependent on the units used, and an energy-level factor.

In view of the importance of the problem, the above relationships perhaps deserve consideration.

BIOPHYSICS

Flow of Blood through Narrow Tubes

IN a recent communication, Haynes[1] describes experiments on the flow through capillary tubes of suspensions of erythrocytes in standard acid–citrate–dextrose and proposes an equation relating volume flow in unit time to applied pressure. He also refers to my use of Casson's equation[2] for somewhat similar results obtained by various authors on blood (treated with coagulants) from a number of species[3,4]. Although Haynes's comments are entirely correct so far as they go, it seems that the matter requires further clarification.

The essential point is that, to further our understanding of the sigma phenomenon in full blood, it is greatly advantageous to be able to describe the flow-curves over a wide experimental range of shear-rate by means of two parameters the variation of which with capillary radius can then be quantitatively studied. Such studies would be less interesting for suspensions of erythrocytes alone than for full blood, except that Dr. Haynes evidently finds (private communication) no difference in the shapes of the pressure-flow curves.

From the form of Casson's equation, it is clear that it cannot express a fundamental law of flow. For example, a reversal of the direction of stress would introduce imaginary quantities; but the straight lines obtained when the square root of shear-rate is plotted against the square root of stress (both at the capillary wall) serve our purpose, since any straight line is definable by its slope and its intercept on extrapolation to some axis. By 'yield-value' is meant only the extrapolated intercept of these straight lines extended to the stress axis.

In a second communication, Reiner and Scott Blair[4] calculated the curvature which would take place if the same equation were to hold for any system down to an experimentally determinable yield-value. We would certainly not have wished to imply that blood has a yield-value in this sense, since none of the published results appeared, at the time, to cover a low enough range of shear-rates to decide the point.

Since these communications were published, more systems have been found to follow Casson's equation (see Heinz[5]), and the extension proposed by us for low shear-rates may well be applicable to some of them.

I am indebted to Dr. R. H. Haynes for his kindness in elucidating a number of points in private correspondence.

METALLURGY

Optical Properties of Bismuth

As part of a programme to investigate applications of the polarizing microscope to metallography, a study has been made using bismuth single crystals. The single crystals were prepared from material of a purity not less than 99·99 per cent bismuth, by controlled solidification from a capillary tube. As a check on purity, X-ray measurement of the unit cell dimensions gave values of $a = 4·5366$ kX., $c = 11·8402$ kX., indexed on a hexagonal basis. Sections of the various crystals were machined flat and electropolished[1]. The orientation of each crystal was determined using the polarizing microscope, a few of the orientations being checked by X-ray back reflexion[2].

The directions of complete extinction (uniradial directions) of each section were set at 45° to the plane of vibration of the polarizer and the rotation of the analyser found which produced extinction in monochromatic light. After rotation of the crystal on the stage by 90° another measurement of the analyser rotation in the opposite sense was obtained. The difference between these two measurements gave twice the analyser rotation angle.

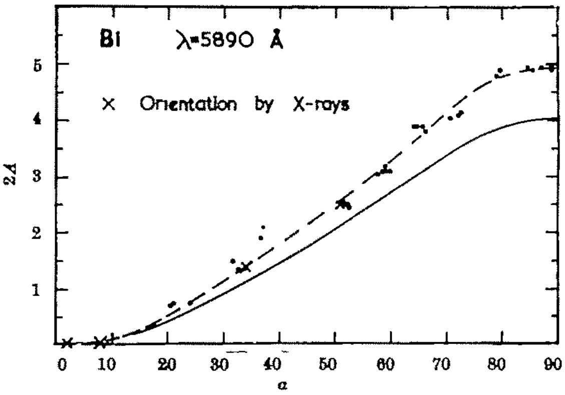

Fig. 1. $2A$, Analyser rotation angle × 2; α, angle between basal plane and plane of section; – – – – –, experimental curve; ———, experimental curve corrected for reflector rotation

Fig. 1 shows the experimental results, using yellow light (5890 Å.) with $2A$, twice the angle of analyser rotation, plotted against the angle α between the optic axis and the normal to the plane of section. The broken line represents the best curve through the experimental points while the solid curve gives the true rotations after making correction for the rotation due to the reflector slip of the microscope. Rotations due to phase differences are included in the rotation angles shown in Fig. 1. These rotations are small and within experimental error, the maximum phase difference at this wave-length being 1·1°. Measurements of phase difference and their effects are shown in Table 1, the figures in the columns headed L being obtained with an elliptic compensator in the tube slot of the microscope.

The reflectivities in the two uniradial directions of a crystal with $\alpha = 87°$ were measured using a Cooke, Troughton and Simms visual microphotometer (Berek type) with a basal section of quartz as a standard. The reflectivities at three wave-lengths and their ratios are given in Table 1, together with

Table 1. Bismuth Single Crystal. Sign of Rotation Negative. Optic Axis [111] inclined 3° to Section Surface. $\alpha = 87°$

Calculated values

Reflectivity Re^2	Reflectivity Ro^2	Reflectivity ratio Re^2/Ro^2	Phase difference $(\Delta e - \Delta o)$
56·1 %	65·1%	0·861	−1·6°

* L, Elliptic compensator used to measure phase difference.

ratios calculated from analyser rotations. The ratio of reflectivities calculated from values of the optical constants (Lenham, A. P., private communication) for the same crystal, is included for comparison.

Measurement of the analyser rotation angle thus provides a rapid method of determining the tilt of the optic axis ([0001] on hexagonal indexing, [111] on both rhombohedral descriptions). The accuracy is probably limited to about ± 5° with standard equipment, but the method can be used with polycrystalline samples even if the grain size is small.

Effect of Moisture on Carboxylic Acid Adsorption to Steel

Qualitative evidence has been given[1] that oils compounded with efficient dicarboxylic (alkylated succinic acids) rust inhibitors will not prevent rusting at certain low concentrations of the additive. When oil at these low concentrations of inhibitor was saturated with water, however, rust protection was obtained. Von Fuchs attributed this behaviour to the chemical reaction of iron with water to form ferrous hydroxide, which in turn can react with the acidic inhibitor to form a tenacious film of soap on the metal surface. Another investigation[2], using stearic acid labelled with carbon-14, demonstrated that the acid is adsorbed more readily to ferrous surfaces from hydrocarbon solution containing entrained moisture than from a relatively dry solution. This phenomenon of enhanced adsorption to the metal surface was explained by Ries *et al.* as probably being due to an increase in the oxide coating produced by the presence of moisture.

In this work it was discovered that the adsorption could be enhanced not only by moisture in the oil, but also by an invisible layer of moisture adsorbed on the metal surface prior to application of the oil. This suggested a means of determining the mechanism of the water catalysis, since if the phenomenon is due to an increase in oxide surface, the effect would be observed on a surface originally treated with moisture even if it were dried thoroughly before applying the inhibited oil.

To determine the relative amounts of carboxylic acid adsorbed from an oil solution on to the back surface of a polished steel planchet, an alkylated succinic acid labelled with carbon-14 was used. Three drops of a 0·015 per cent solution of the acid in mineral oil were deposited on a planchet surface. After 2 min. of contact at room temperature, the oil was blotted off thoroughly with filter paper and the radioactivity remaining on the planchet determined. This residual activity is equal to the activity adsorbed to the surface plus the activity remaining in the thin film of oil not removable by blotting. Any increase in this total residual activity resulting from variations in preparation of the metal surface must be due, of course, to increased adsorption of the radioactive species to the surface. Treatment of the polished planchets before depositing the radioactive oil consisted of exposure to a column of steam for varying periods of time ranging from 30 sec. to 4 min. After this exposure, the visible layer of condensed steam was allowed to evaporate, leaving behind the invisible film of adsorbed moisture. Half the metal samples thus obtained were immediately treated with inhibited oil. The other half were dried in an oven at 120° C. for 3 days to remove the invisible adsorbed film of moisture, before application of the oil. The results of the experiments are given in Table 1.

Table 1. EFFECT OF MOISTURE ON ADSORPTION OF AN ALKYLATED SUCCINIC ACID ON TO SMOOTH STEEL SURFACES

Sample No.	Exposure to steam (sec.)	Resulting condition of surface	Heat drying treatment after steam exposure	Residual activity after blotting off oil (counts/min)
1	0			438
2	0			464
3	30	no visible rust	none	824
4	30	no visible rust	120° C. for 3 days	372
5	30	no visible rust	120° C. for 3 days	398
6	60	incipient rusting	none	1,155
7	60	incipient rusting	none	1,451
8	60	incipient rusting	120° C. for 3 days	534
9	60	incipient rusting	120° C. for 3 days	464
10	240	heavy rusting	none	1,833
11	240	heavy rusting	120° C. for 3 days	568

It can be seen that even if the surface oxide area of a steel specimen is enormously increased through exposure to moisture, there is little increase in absorption if the surface is dried thoroughly before applying the oil. On the other hand, surfaces exposed to moisture under conditions resulting in very little increase in the surface oxide area will undergo a tremendous increase in adsorptive capacity for carboxylic acids if the adsorbed layer of water molecules is not removed before treatment with the acid. The effect of water in increasing the adsorption of carboxylic acids from oil solution on to iron surfaces is consequently not due primarily to an increase in the surface oxide area of the metal, but rather to direct participation of the water at the time of the adsorption reaction.

The opinions or assertions contained in this communication are our own and are not to be construed as official or reflecting the views of the Naval Service at large.

RADIATION CHEMISTRY

Chemical Effects of Ionizing Radiation on Deoxyribonucleic Acid in Dilute Aqueous Solution

When purine and pyrimidine nucleotides in dilute aqueous solution are irradiated with ionizing radiation they are destroyed by two pathways[1]. The minor pathway is attack upon the sugar moiety followed by release of free base[1]. Details of the mode of sugar attack have not been established; but possible reactions have been suggested by Daniels *et al.*[2]. The major pathway is attack of the base moiety which with purines in the absence of oxygen yields the corresponding formamido-pyrimidine nucleotide[3]. When pyrimidine nucleotides are irradiated in the absence of oxygen sugar phosphate is liberated, but there is no ultra-violet absorbing product arising from base attack. When oxygen is present during irradiation G-values (molecules per 100 eV.) for nucleotide destruction are increased 2–3 times[4]. For purine nucleotides the increased degradation in oxygen is almost entirely an augmented base attack, but no ultra-violet product arising from it is found[4]. When pyrimidines are irradiated in the presence of oxygen hydroxy-hydroperoxides are formed[5]. G-values for destruction of pyrimidines in the presence of oxygen are greater than those for purines[1,4] and suggest that when deoxyribonucleic acid is irradiated pyrimidines will be destroyed to a greater extent. Extrapolation of the effects of radiation upon nucleotides to effects upon deoxyribonucleic acid is complicated in an uncertain way by the influence of internucleotide linkages and hydrogen bonding of base pairs. This communication reports the amounts of base and sugar destroyed when aqueous solutions of calf thymus deoxyribonucleic acid are irradiated.

To determine whether radiochemical changes varied with different samples of deoxyribonucleic acid the chemical changes were compared after irradiating samples of calf thymus deoxyribonucleic acid from four separate preparations. Solutions of approximately 5 mgm. acid/ml. were prepared with triple-distilled water and neutral phosphate buffer added (final concentration 10^{-2} M). Air bubbles were removed by cautious evacuation, but solutions were irradiated under air. Solutions were irradiated with 15-MeV. electrons to a dose of 10^6 rads. It is assumed that the initial 7 × 10^5 rads use up all dissolved oxygen[1] and since the dose is delivered within 90 sec. the remaining 93 per cent of the dose is delivered to an oxygen-free solution. Samples of control and irradiated solutions were hydrolysed in hot perchloric acid and their base compositions determined by paper chromatography[7]. The total base change was 10 per cent of the control. G-values for bases changed were calculated and are given in Fig. 1. There is little variation between samples of deoxyribonucleic acid, and thymine is destroyed to the greatest extent. Perchloric acid hydrolysis gives a low value of thymine[7], and it seemed possible that as irradiated material is degraded the yield of thymine may be further lowered, giving an artificially high value for G(–thymine). However, when the hydrolysis was repeated with formic acid at 175° C., which does not give a low value for thymine[7], G-values were essentially the same as obtained after perchloric acid hydrolysis. When samples of irradiated deoxyribonucleic acid are run on paper in an n-propanol–water solvent[8] all phosphates remain at the origin and free bases can be isolated. Adenine, guanine, cytosine and thymine were isolated when 1-ml. samples of irradiated deoxyribonucleic acid were run on paper, and their yields were determined from the ultra-violet absorption of their eluates (Fig. 2). Amounts of base released, that is, sugar attacked, are approximately one-quarter of the amounts of base destroyed. G-values for adenine and cytosine released are slightly higher than those for guanine and thymine. It is not readily possible to determine amounts of free base, if any, present in the control solution. If any free base is present it will only strengthen the conclusion that base attack is the major reaction.

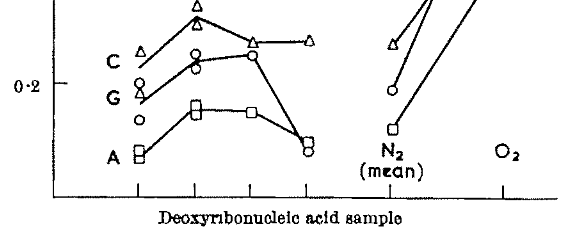

Fig. 1. G-values for bases destroyed when aqueous solutions of calf thymus deoxyribonucleic acid (5 mgm./ml.) are irradiated with 15-MeV. electrons. □, Adenine; ○, guanine; △, cytosine; ●, thymine

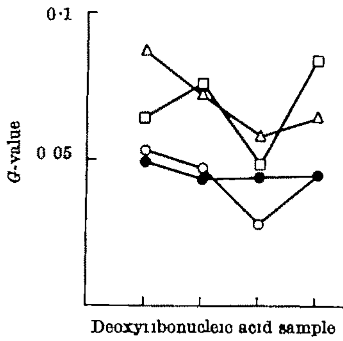

Fig. 2. G-values for bases released when aqueous solutions of calf thymus deoxyribonucleic acid are irradiated with 15-MeV. electrons in the absence of oxygen. □, Adenine; ○, guanine; △, cytosine; ●, thymine

In addition to free bases, 2 : 4-diamino-5-formamido-6-hydroxypyrimidine is found in irradiated deoxyribonucleic acid and arises from attack on the guanine moiety[3]. Amounts of 2 : 4-diamino-5-formamido-6-hydroxypyrimidine are smaller than G(–guanine), but are increased by warming the irradiated deoxyribonucleic acid solution, at pH 7 and 80° C., for 1 hr. It is assumed that attack upon guanine yields 2 : 4-diamino-5-formamido-6-hydroxypyrimidine attached to the sugar by a labilized glycosidic linkage. Attack on adenine forms the corresponding formamido-pyrimidine[4], but none could be found in the irradiated deoxyribonucleic acid. However, amounts of adenine changed are small and the formamido-pyrimidine could easily escape detection.

A solution of deoxyribonucleic acid, concentration 2 mgm./ml., was irradiated to 1·7 × 10^6 rads, the solution being kept saturated with oxygen during irradiation. Control and irradiated solutions were hydrolysed in perchloric acid and the base composition determined (Fig. 1). While the total amount of base destroyed is 2·5 times greater in the presence of oxygen, the relative amounts of each base destroyed are approximately the same as when oxygen is absent. The G-value for adenine released in the presence of oxygen is 0·06, which is close to the value in the absence of oxygen. This is consistent with the finding with purine nucleotides that enhancement by oxygen is an increased attack upon the base moiety.

When tissue is irradiated, it is likely that the effects of the indirect action will be the same as *in vitro*. Assuming *G*-values for an aqueous solution, irradiation of tissue to a dose of 10^3 rads will change one base in 10^4. If it is assumed that cell constituents, adjacent to nucleic acid, compete 10 times (or 100 times) more efficiently than deoxyribonucleic acid for radicals there will be one nucleotide changed in 10^5 (or 10^6) per 10^3 rads. Damage of this extent would be expected to interfere severely with the function of the cell. The changes produced in the absence of oxygen will be removal of pyrimidines and conversion of purines to formamido-pyrimidines. Since the latter have labile sugar-linkages the ultimate result may be removal of purines. For every four bases removed one sugar will be attacked and presumably the sugar–phosphate backbone will be broken. Oxygen, present during irradiation, will increase the amount of base destroyed by a factor of 2·5, but sugar breakage will be little changed. Thus the indirect action of ionizing radiation upon the bases of deoxyribonucleic acid seems to be adequate to account for observed biological damage and for the increase in damage of approximately 2·5 times in oxygen, observed for a wide array of biological changes[9].

The action of alkylating agents on deoxyribonucleic acid sheds further light on the chemical changes in deoxyribonucleic acid which may be important biologically. P. Brookes and P. D. Lawley (personal communication) have shown that when deoxyribonucleic acid is treated with low doses of an alkylating agent, guanine is alkylated to a much greater extent than the other three bases. Alkylation of the guanine moiety labilizes the glycosidic link, which is slowly hydrolysed.

It is interesting to speculate that biological changes brought about by alkylating agents and ionizing radiation are associated with removal of guanine from deoxyribonucleic acid. Further, radiobiological changes not produced by alkylating agents may be associated primarily with removal of thymine.

I am indebted to Prof. J. A. V. Butler, who so kindly supplied samples of calf thymus deoxyribonucleic acid, and gratefully acknowledge financial support by the William Shepherd Fellowship. CHEMISTRY

The Tesla-coil Method for producing Free Radicals from Solids

MOST of the methods in current use for producing radicals from crystalline solids for study by electron spin resonance involve the use of high-energy radiation and therefore require comparatively expensive and elaborate equipment. Papazian[1,2] showed that several substances, including hydrazoic acid and methyl iodide, condensed from the vapours at liquid-nitrogen temperature developed colour when sparked with a Tesla-coil ; this was attributed to free-radical formation. Using the electron spin resonance technique we have found that radical concentrations as high as 10^{18}/gm. (approximately 10^{-3} mole $l.^{-1}$) can be obtained by applying the discharge from an ordinary vacuum leak-tester to finely ground crystals of many organic substances contained in partially evacuated electron spin resonance specimen tubes. For low-melting solids, for example some vinyl monomers, the following procedure is sometimes convenient. The degassed liquid is frozen in a thin layer on the walls of the evacuated tube, which is then cooled to −195° C. and vibrated vigorously. The crystals are thus detached from the walls and deposited in a fine powder at the bottom of the tube. A suitable gas at a pressure of about 0·1 mm. mercury is admitted and the probe of the Tesla-coil applied in the neighbourhood of the crystals, the tube being maintained at a low temperature and preferably vibrating. With high-melting solids it suffices to grind the crystals finely in a mortar before introduction into the specimen tube. Nitrogen, hydrogen, argon and oxygen have been used, in order of decreasing effectiveness. The presence of a gas is desirable but not absolutely essential. The spectrum obtained is independent of the nature of the gas. Radical concentrations of the order of 10^{-4} mole $l.^{-1}$ are often produced in a few seconds by this technique. Substances examined include glycine, diketopiperazine, acrylamide, potassium and lithium methacrylates, acrylic, methacrylic, *n*-butyric and itaconic acids, acrylonitrile and polyacrylonitrile, all of which gave strong radical spectra. Surprisingly, a negative result was obtained with azo-*bis*-*iso*butyronitrile. The radicals from these compounds show widely differing thermal stabilities and reactivities towards oxygen.

Methacrylic acid was selected for further study. The spectra obtained were identical to those produced by γ-irradiation of methacrylate polymers[3]. The limiting radical concentration which could be obtained with prolonged excitation by the Tesla-coil at about −195° C. was approximately 10^{-3} mole $l.^{-1}$. It is interesting that this value is within an order of magnitude of the number of radicals in a unimolecular layer on the surface of the crystals (estimated from simple microscopic examination of the crystal size), and we believe that the radicals formed with excitation by the Tesla-coil reside mainly on the surface initially. In agreement with this it was found that at − 78° C. the radicals react with oxygen to form new radicals with an asymmetric spectrum of the type given by *R*OO· (ref. 4) in a time too short to permit observation with the present apparatus, that is to say, within 30 sec. On the other hand, the reaction with nitric oxide at a pressure of 17 mm. mercury at the same temperature is comparatively slow, with a half-life of about 1 hr.

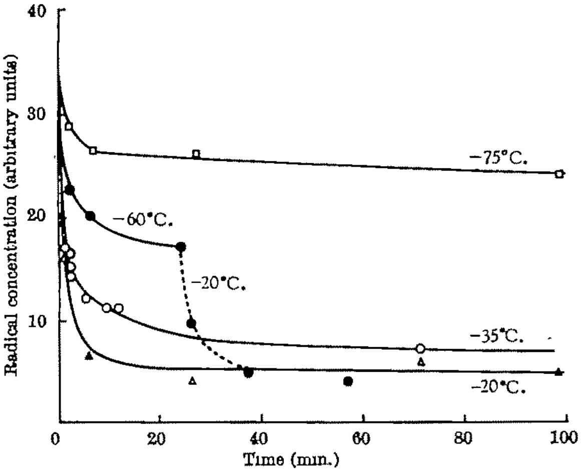

Fig. 1. Decay of surface radicals on methacrylic acid crystals at various temperatures. Scale of radical concentration is arbitrary, but 30 units = 10^{-3} mole l.$^{-1}$, approximately. Different symbols are used to distinguish between different experiments

On warming a specimen containing the initial radicals to 0° C. for 5 min. the radical concentration decays to the limit of detectability (10^{-6} mole l.$^{-1}$ approximately). The effects of warming to various temperatures between −195° C. and 0° C. are shown in Fig. 1. The abscissa represents the total time at the appropriate temperature; spectra were always taken with the specimen at −195° C. At each temperature there is an initial comparatively rapid decay to an almost stationary value, and is found to be inversely proportional to the temperature.

The dotted curve shows the result of an experiment at two temperatures. After excitation by the Tesla-coil, the tube was warmed for 24 min. to −60° C. to achieve the stationary concentration at this temperature, and then warmed to −20° C. for successive short periods. This treatment resulted in a decay in radical concentration to the stationary value for −20° C.

These results are understandable if the radicals on the surface of the crystals are immobile at −195° C. but became progressively mobilized as the temperature is raised. Such would be the case if the energies binding the radicals to the surface were distributed over a wide spectrum. Possibly the radicals are not entirely monomeric; the mobility would then depend on the degree of polymerization.

With repeated excitation by the Tesla-coil at −195° C. and warming to 13° C. a high radical concentration (10^{-3} mole l.$^{-1}$) may be built up. These radicals are stable at 13° C., but react rapidly with oxygen. It would appear that a surface polymerization had occurred in this experiment, producing large immobile radicals. In a similar experiment with *n*-butyric acid no such effects were observed.

These experiments illustrate some of the possible uses of this simple technique, which may have applications not only in the study of free radicals, but also in the investigation of surface reactions.

Polymerization of Crystalline Methacrylic Acid initiated by Ultra-violet Radiation

In recent years it has been shown that a number of crystalline vinyl monomers polymerize when irradiated by γ-rays[1–4] or high-energy electrons[5]. However, there appears to be no report in the literature of the ultra-violet initiation of solid-state polymerization, although this process could, in principle, facilitate elucidation of the mechanism of the reaction.

We have found that crystalline methacrylic acid (m.p. 16° C.) may be polymerized by radiation from a high-pressure mercury arc using a quartz optical system, or with azo-*bis*-*iso*butyronitrile as photosensitizer using a 'Pyrex' glass system. In these experiments the crystals had a water content of approximately 0·01 per cent w/w; the presence of some water appears necessary for polymerization, at least in the sensitized reaction. In this latter case the rate falls off after a comparatively small conversion which increases with the concentrations both of the sensitizer and water at 13° C. On the other hand, the unsensitized reaction is autocatalytic in the early stages and may ultimately lead to complete conversion.

The rate in the early stages of the sensitized reaction is proportional to the first power of the light intensity and of the concentration of sensitizer. Measurements of the kinetic chain-length made using sensitizer labelled with carbon-14 ($4·3 \times 10^{-3}$ mole l.$^{-1}$) give values of approximately 700 in the early part of the reaction, substantially independent of the light intensity. This corresponds to a rate of chain starting of $5·0 \times 10^{-7}$ mole l.$^{-1}$ sec.$^{-1}$ under our standard 'high-intensity' conditions, and a rate of polymerization of $3·5 \times 10^{-4}$ mole l.$^{-1}$ sec.$^{-1}$. Under the same conditions the decomposition of the sensitizer was followed by observing the nitrogen evolution, and thus the efficiency of initiation was estimated. It turns out to be approximately 0·5, that is, not very different from that found in liquid-phase polymerizations.

After irradiation radicals can be detected in the frozen mass by electron spin resonance. Their concentration increases with the period of irradiation, and also strongly with the sensitizer concentration. In the range of sensitizer concentrations studied (up to $1·3 \times 10^{-2}$ ml.$^{-1}$) only a small fraction of the total radicals produced by the light—approximately 10 per cent—become permanently trapped. These radicals are stable for long periods at 0° or 13° C., no detectable change occurring during 17 hr. at 0° C. The permanently trapped radicals are apparently located in sites unsuitable for further propagation, since no after-effect could be detected even in periods up to 17 hr. at 13° C. The spectrum of the radicals is the same as that observed in γ-irradiated methacrylate polymers by Abraham, Melville, Ovenall and Whiffen[6]. On admission of oxygen the spectrum changes to the asymmetric type shown by $RO O·$ radicals[7].

When irradiation is carried out in the presence of oxygen which is admitted to the system after crystallization is complete the polymerization proceeds normally. Since the liquid-phase photopolymerization is strongly inhibited by oxygen the propagating radicals in the solid must be inaccessible to oxygen. On the other hand, the permanently trapped radicals appear to be situated on the surface of the solid.

The degrees of polymerization of the polymers, determined viscometrically, varied in a rather erratic manner, but were generally around 4,000, independent of the rate of initiation. Since this value is considerably greater than the kinetic chain-length, the polymers must be markedly heterodisperse, perhaps owing to the fact that the sensitizer in these experiments was not uniformly distributed throughout the specimens. The crystals were prepared by freezing solutions of the sensitizer in the liquid monomer, and it was shown by ultra-violet absorption measurements that the first crystals to separate contained a relatively low concentration of sensitizer.

The above experiments do not establish that propagation through the crystal lattice occurs. The actual locus of polymerization is being determined by irradiating both large single crystals and thin crystal layers coupled with microscopic observation. Preliminary results indicate that the polymerization is at least partly a phase-boundary reaction.

A Monte Carlo Equation of State for Mixtures of Hard-Sphere Molecules

PROGRESS in the theory of mixtures is limited by the lack of adequate approximate solutions of the classical many-body problem. Thus at densities greater than those appropriate to the virial expansion no satisfactory estimate of the properties of mixtures is possible. However, the Monte Carlo method enables the evaluation of the many-dimensional configurational integral to be performed by a sampling procedure. The method is applicable to any form of intermolecular potential.

The preliminary investigations of the properties of mixtures were made on mixtures containing two types of hard-sphere molecules with a ratio of diameters $\sigma_\beta/\sigma_\alpha = 1{\cdot}667$. Systems of 32 and 64 molecules were studied, the molecules being confined in a cubic space by means of periodic boundary conditions[1-3]. Initially the two species of molecules were distributed randomly on a face-centred or simple cubic lattice. New configurations were generated by moving one particle at a time, and the results analysed in terms of three cumulative distribution functions, corresponding to the three types of molecular interaction in the mixture. A check of the method, using 'mixtures' of molecules of equal size, showed internal consistency among the distribution functions and good agreement with the results for single-component systems obtained by Wood and Jacobson[4] and Alder and Wainwright[5]. In the case of mixtures the validity of the method was examined by comparing the results obtained from systems with different numbers of molecules and with differing distributions of the two species on the initial lattice. The agreement is illustrated by the following values of pV/RT for an equimolar mixture at a reduced density, $1/V^*$, of 0·5: 32 molecules, 2·95; 32 molecules, initial distributions interchanged, 3·07; 64 molecules, 3·01;

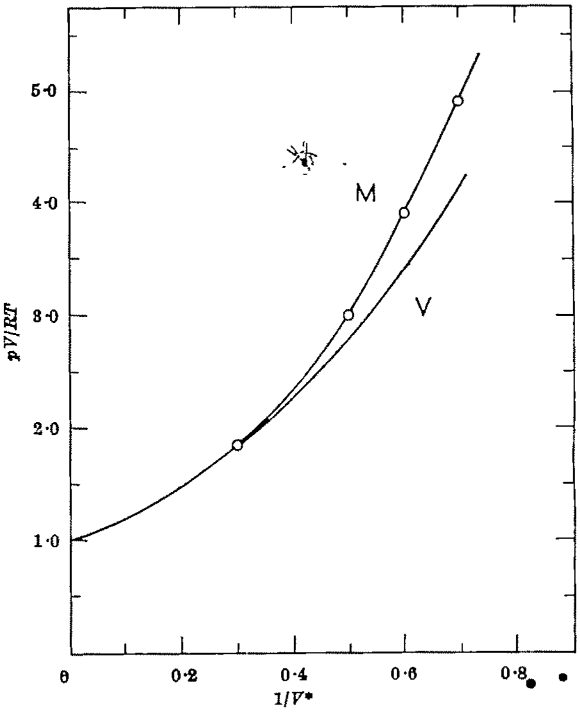

Fig. 1. pV/RT as a function of $1/V^*$ for an equimolar mixture of hard spheres for which $\sigma_\beta/\sigma_\alpha = 1{\cdot}667$. The lower line ($V$) represents the results of the virial expansion and the upper line (M) is that obtained from the Monte Carlo calculations

where N_α is the number of molecules of type α and σ_α is their diameter. V is the volume of the system.

Fig. 1 shows the equation of state for molecules of the given size ratio in an equimolar mixture over a range of density. The lower curve represents the results obtained from the virial expansion[6], which are consistent with the Monte Carlo results at lower densities but deviate markedly at higher densities.

A full investigation is now being undertaken to determine the effect of different size ratios and to examine the thermodynamic properties of mixtures of varying composition.

The calculations were performed on the Ferranti Mercury computer at the Computing Laboratory, University of Oxford. Considerable computing time has been required, and we wish to thank Miss S. A. Tilley for her interest and assistance.

Spectroscopic Applications of Photographic Emulsion Mosaics

A COMPREHENSIVE spectral survey over as wide a wave-length range as possible is a frequent early requirement during spectroscopic studies of terrestrial and astronomical light sources. Such surveys are often made with low-dispersion prism spectrographs, and sometimes with grating instruments.

The availability of Kodak *O* to *Z* emulsions[1] (and similar emulsions of other manufacturers, for example Ilford *Q* emulsions), each sensitized to have a maximum response in a different wave-length region, enables a spectroscopic survey to be made by a sequence of separate exposures of different emulsions, each selected on the basis of wave-length range of maximum sensitivity. In cases where only one exposure is possible or practicable (for example, to transient and/or very feeble light sources) one specific emulsion (for example, 1–*N* or 103 *aF*) is often used as the most acceptable compromise for high sensitivity over as wide a wave-length range as possible. The inherent variations in the sensitivity of a single emulsion over the wide wave-length range often give rise to non-uniformly exposed plates.

The availability of the Kodak emulsions on films, however, makes it possible to assemble mosaics made up of two or more segments of different emulsions, each easily cut to a length specific to the wave-length range of its maximum sensitivity. For example, the "Kodak Data" book[1] specifications of relative emulsion sensitivity (defined therein as the reciprocal of the exposure to tungsten radiation in metre candles seconds which will produce a density of 0·6 above gross fog when the material is developed for the recommended time in Kodak developer *D*–19) show that a mosaic of optimum sensitivity to 9000 Å. may be assembled by using type *O* emulsion to 5000 Å., type *F* emulsion between 5000 Å. and 7000 Å., and type *N* emulsion between 7000 Å. and 9000 Å. In addition, the range of optimum sensitivity can be extended, if required, to 12,000 Å. by using hypersensitized *M* emulsion between 9000 Å. and 9800 Å., hypersensitized *Q* emulsion between 9800 Å. and 10,200 Å., and hypersensitized *Z* emulsion between 10,200 Å. and 12,000 Å.

The gain in sensitivity obtained by the use of an optimum emulsion mosaic in place of a single emulsion is illustrated in Fig. 1, compiled from individual sensitivity curves given in the "Kodak Data" book. An emulsion mosaic assembled in the manner specified above is a detector the sensitivity of which as a function of wave-length is an envelope of the individual curves of Fig. 1. The response of *O* emulsions is not given in the "Kodak Data" book below 4000 Å., but, as is well known, *O* emulsions perform adequately between 2000 Å. and 5000 Å. The mosaic sensitivity can be extended to shorter wave-lengths by use of Ilford *Q* emulsions or other Schumann type emulsions.

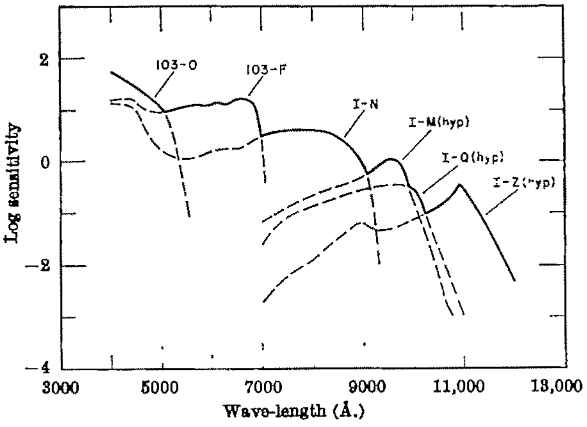

Fig. 1. Relative sensitivity of Kodak emulsions and optimum sensitivity of emulsion mosaic (solid curve)

The practicability of using emulsion mosaics has been tested by using segments of 103–*aO*, 103–*aF*, and 1–*N* 16 mm. film in conjunction with Hilger medium quartz and medium glass spectrographs. A flexible rectangular brass plate (10 in. × 4 in.), to which brass guides were attached to hold the film segments, was used in the spectrograph plate holder in place of the usual glass plate. Each segment of film, of a length appropriate to its wave-length range of maximum response, was cut with slightly oblique ends, which matched those of its neighbours. In this way no spectral features were lost at the boundaries between segments. The mosaic, and separate strips of *O*, *N*, and *F* film equal in length to the mosaic, were exposed for equal times to a microwave discharge through carbon dioxide the spectrum of which is rich in carbon monoxide features over the entire wave-length range of each spectrograph. In contrast to the abrupt variations in exposure obtained along each of the single emulsions, a relatively uniformly exposed spectrum was obtained in each case on the mosaic as expected.

The invaluable assistance of Mr. G. E. Beale, jun., in this work is gratefully acknowledged.

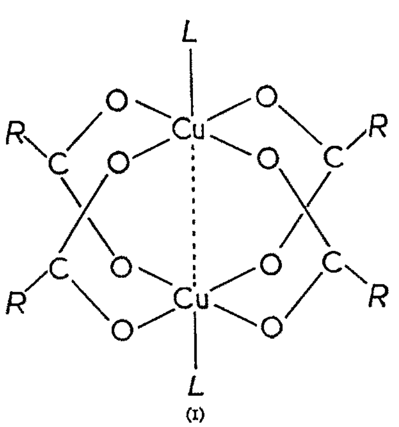
Nature of Cupric Alkanoate Solutions

THAT the cupric salts of alkanoic acids occur in the solid state in the form of dimeric molecules is shown by van Niekerk and Schoening's X-ray analysis of cupric acetate hydrate (I, $R = CH_3$, $L = H_2O$)[1] and by Martin and Waterman's magnetic studies of the acetate and some higher homologues in hydrated and anhydrous forms[2]. Tsuchida and Yamada have shown that a further characteristic of this structure is the occurrence of an absorption band about 375 mμ, polarized in the copper–copper axis, in addition to the usual 'copper band' about 700 mμ[3,4].



(I)

Martin and Waterman extended their observations to the dissolved state and showed that the dimeric structure persisted in dioxane solution, arguments from the magnetic properties being supported by cryoscopic measurements of molecular weight and the appearance of an absorption band about 375 mμ[5]. Since the anhydrous compounds were found to be insoluble in non-donor solvents (though some of the higher homologues became dispersed), the species present in solution were presumably dioxane solvates (I, $L = C_4H_8O_2$).

Further evidence of the existence of dimeric molecules in solution is provided by a study of the distribution of cupric propionate between water and chloroform in the presence of propionic acid[6], distribution constants of the form :

$$k = \frac{[\mathrm{Cu}]_{\text{aqueous phase}}}{\sqrt{[\mathrm{Cu}]_{\mathrm{CHCl_3}\text{ phase}}}}$$

being interpreted in terms of the partition equilibrium:

$$2\,\mathrm{CuPr}^+ + 2\,\mathrm{Pr}^- \rightleftharpoons \mathrm{Cu_2Pr_4}$$

Table 1. DISTRIBUTION CONSTANT AND PROPIONIC ACID CONCENTRATION

$[\mathrm{CuPr_2}]$ (mole/l.)	0·039	0·039	0·055	0·055	0·055	0·077	0·077	0·077
[HPr] (mole/l.)	0·14	0·20	0·115	0·20	0·29	0·16	0·28	0·44
k	0·45	0·34	0·45	0·38	0·32	0·43	0·34	0·28
$k\sqrt{[\mathrm{HPr}]}$	0·17	0·15	0·15	0·17	0·17	0·17	0·18	0·19

Variation of the values of k with propionic acid concentration was attributed to the suppression of hydrolysis, but it is now suggested that this variation, which can be expressed in the form :

$$k \propto \frac{1}{\sqrt{[\mathrm{HPr}]}}$$

(Table 1), shows that the cupric propionate is dissolved in the organic phase, not as unsolvated molecules but as the propionic acid solvate (I, $R = C_2H_5$, $L = C_2H_5COOH$), thus accounting for the insensitivity of the absorption spectra to changes of the extracting solvent. The partition equilibrium now becomes :

$$2\mathrm{CuPr}^+ + 2\mathrm{Pr}^- + 2\mathrm{HPr} \rightleftharpoons \mathrm{Cu_2Pr_4(HPr)_2}$$

Since the anhydrous cupric alkanoates are insoluble in non-donor solvents, further evidence for solvation by the free acids was sought by determining their solubilities in chloroform in the presence of free acid. Table 2 shows the solubilities (determined iodimetrically) of anhydrous cupric acetate, *iso*butyrate and crotonate in the presence of the corresponding acids.

Table 2. SOLUBILITY AND FREE ACID CONCENTRATION (AT 25° C.)

As the free acids are known to be mainly dimeric in chloroform solution, the linear relationship between solubility and free-acid concentration shows that the dissolved species is the solvated dimer in accordance with the equilibrium :

$$\mathrm{Cu_2}A_4 + (\mathrm{H}A)_2 \rightleftharpoons \mathrm{Cu_2}A_4(\mathrm{H}A)_2$$

All these solutions have absorption bands at 675 mμ (ε ~ 200 per atom of copper) and 375 mμ (ε ~ 60 per atom of copper). The band at 675 mμ is sensitive to changes of solvate, addition of pyridine causing a shift to 710 mμ and of dioxane to 655 mμ (as found by Martin and Waterman in dioxane solution). The wide occurrence of the solvated dimeric structure in solution is shown by the observation of this pattern of absorption by the cupric compounds of the following acids : acetic, propionic, butyric, *iso*butyric, *n*- and *iso*-valeric, pivalic, caproic, octoic, lauric, stearic, β-chloropropionic, β-phenylpropionic, phenylacetic and crotonic.

The resistance of cupric formate to the formation of the dimeric structure has been studied by Martin and Waterman[7], who observed the characteristic absorption pattern in 90 per cent aqueous formic acid solution and in formic acid/acetone, the absorption bands being at 360 mμ, 745 mμ and 375 mμ, 675 mμ respectively. It now seems probable that the latter solution contains the formic acid solvate (I, R = H, L = HCOOH) and not, as they suggest, the acetone solvate and that the former contains a mixture of this with hydrated monomeric species.

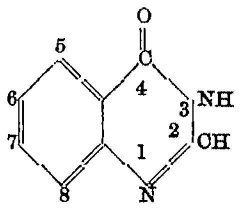
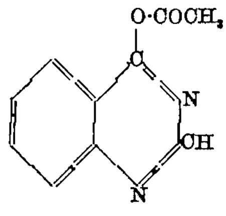
Acetylation of 4-Quinazolone

THE sodium salt of 4-quinazolone[1] is known to give 3-substituted derivatives on alkylation[1]. In the hope of preparing 3-acetyl-4-quinazolone, the sodium salt of 4-quinazolone was subjected to acetylation. When carefully dried sodium salt of 4-quinazolone was made to react with acetyl chloride in dry dioxane, a colourless crystalline compound $C_{10}H_8O_2N_2$, was isolated. The same derivative was obtained by refluxing 4-quinazolone with large excess of acetic anhydride. Extreme care was necessary in excluding water during the preparation and purification of this compound.



I



II

The new compound has high lability towards water. Slight trace of water in the solvent or exposures to moist air decomposed it into 1 mole of 4-quinazolone and 1 mole of acetic acid even at room temperature.

The reduction of this labile compound with lithium aluminium hydride gave 4-quinazolone in good yield. As an N-acetyl group would be expected to give an

N-ethyl group and an O-acetyl group would be de-acetylated, the results of the lithium aluminium hydride reduction imply that the labile derivative is 4-acetoxyquinazoline (II).

BIOCHEMISTRY

Development of 5-Hydroxytryptophan Decarboxylase Activity in Rat Kidney

The studies of Udenfriend and his co-workers[1] indicate that tryptophan is first oxidized to 5-hydroxytryptophan and then decarboxylated, resulting in the formation of 5-hydroxytryptamine. The latter reaction requires the presence of a specific enzyme, 5-hydroxytryptophan decarboxylase[2]. The purpose of the present communication is to describe the development of this enzyme system in the kidneys of fœtal, new-born, and adult rats.

In these experiments, albino rats of the Sprague–Dawley strain were used. All animals were killed by a sharp blow on the head and bled from the neck. The kidneys were removed and homogenized in 4 ml. of distilled water with a Potter–Elvehjem tissue grinder. Enzyme activity of kidney and adult rats was determined individually. In the case of rats younger than 21 days of age, the kidneys from litter mates were pooled and homogenized in 3 ml. of distilled water. The incubation mixture, consisting of 10 μmoles of 5-hydroxy-DL-tryptophan (Sigma Chemical Company) in 2·7 ml. of 0·1 *N* sodium pyrophosphate buffer, *p*H 8·0, was first gassed with nitrogen for 5 min. After agitation with nitrogen for 10 min., 0·3 ml. of rat kidney homogenate was added and the mixture was shaken in a nitrogen atmosphere at 38° C. in a Dubnoff metabolic incubator for a period of 2 hr. The reaction was stopped by the addition of 3·0 ml. of 10 per cent trichloracetic acid. After centrifugation, 3·0 ml. of the supernatant was removed, and the 5-hydroxytryptamine formed was determined by the colorimetric method of Udenfriend *et al.*[3]. All the experiments were carried out in duplicate. The results were expressed as μmoles of 5-hydroxytryptamine formed per 100 mgm. dry weight of kidney per hr.

Table 1 shows the 5-hydroxytryptophan decarboxylase activity of kidneys of rats of various ages. The results indicate that the enzyme was inactive in the fœtus and shortly after birth, and gradually increased to adult-levels over a period of several weeks.

Table 1. Kidney 5-Hydroxytryptophan Decarboxylase Activity in Rats of Different Ages

Age	No. of exp.	No. of animals	5-Hydroxytryptophan decarboxylase activity*
Fœtal†	3	45	0
1 day	3	23	0
2–5 days	4	24	0 21 ± 0 21
7–12 days	5	26	0·38 ± 0·10
21–23 days	7	21	0·66 ± 0·13
33 days	4	8	1 19 ± 0·47
Adults	14	14	1·34 ± 0·58

* Mean values expressed as μmoles 5-hydroxytryptamine formed per 100 mgm. of dry weight of kidneys per hr.
† 1–3 days before term.

Buzard and Nytch[4] have shown that pyridoxal phosphate is a co-factor for rat kidney 5-hydroxytryptophan decarboxylase. The possibility that the low activity of this enzyme in fœtal and new-born rat kidneys may be caused by a deficiency of this co-factor was tested by adding 0·1 and 0·8 μmole pyridoxal phosphate to the incubation mixture. Table 2 shows that although excess amounts of pyridoxal phosphate increased the formation of 5-hydroxytryptamine two- to three-fold in the older and adult rat kidney homogenates, as has previously been reported[4], the addition had only a minimal effect in the fœtal and new-born homogenates. This was also tested *in vivo* by the intraperitoneal injection of 50 mgm. of pyridoxine hydrochloride to a pregnant rat three days prior to delivery. Assay of 5-hydroxytryptophan decarboxylase in the new-born rat kidney homogenate in this litter failed to show any demonstrable enzyme activity.

Table 2. Effect of Pyridoxal Phosphate Supplementation upon 5-Hydroxytryptophan Decarboxylase Activity

Age	5-Hydroxytryptophan decarboxylase activity*		
	Without supplementation	0 1 μM PP added	0 8 μM PP added
Fœtal	0	0 09	0 15
1 day	0	0	—
2 days	0	0·19	0·19
3 days	0·40	0·43	0 62
11 days	0 44	0 62	0·71
21 days	0·83	3·10	—
21 days	0 78	2 85	—
23 days	0·65	1·56	1 77
Adult	1·34	3 01	—
Adult	0·82	2·38	—
Adult	0 65	1 84	—
Adult	0·69	1·62	1 57

* Mean values expressed as μmoles of 5-hydroxytryptamine formed per 100 mgm. dry weight of kidneys per hr.

Finally, reports have appeared showing the inhibition of 5-hydroxytryptophan decarboxylase by carbonyl reagents, metal chelating agents, cupric ions, phenylalanine derivatives, substituted indoles and norepinephrine. Because of this possibility, mixture experiments using rat kidney homogenates were carried out with the following results, expressed in terms of 5-hydroxytryptamine formed: 0·3 ml. fœtal homogenate, 0; 0·15 ml. fœtal and 0·15 ml. adult mixed, 0·40 μmole; and 0·3 ml. adult, 1·06 μmoles. In order to rule out the possibility of non-protein inhibitors, rat kidney homogenate from a young animal was boiled at 100° C. for 3 min. The supernatant had no effect on the 5-hydroxytryptophan decarboxylase activity in adult rat kidney. While this does not positively rule out the possibility of an inhibitor, the evidence would seem to suggest that the low activity of 5-hydroxytryptophan decarboxylase activity in fœtal and new-born rat kidney probably represents a low inherent activity of the enzyme itself[4].

A deficiency of 5-hydroxytryptophan decarboxylase in the fœtal rat kidney is of interest because of the part the enzyme plays in the central nervous system. For example, Amin *et al.*[5] have shown the synthesis of 5-hydroxytryptamine from its immediate precursor 5-hydroxytryptophan and that it is stored in particular regions of the grey matter of the brain[5]. In animal experiments, Feldberg and Sherwood[6] have described characteristic changes in behaviour following the injection of 5-hydroxytryptamine into the cerebral ventricles. The inhibition of 5-hydroxytryptophan decarboxylase by phenylalanine metabolites has also been demonstrated *in vitro*[7]. This may in part account for the lowered levels of circulating 5-hydroxytryptamine and urinary 5-hydroxyindoleacetic acid in patients with phenylketonuria. The pattern of development of this enzyme system in the fœtal brain and the part this may play in the central nervous system in phenylketonuria is being explored.

In any event, the decreased activity of 5-hydroxytryptophan decarboxylase in fœtal and new-born rat kidney can now be added to the growing list of enzyme deficiencies in the new-born period[8], which now includes glucose-6-phosphatase, glucuronyl transferase, histidase, and the hepatic tyrosine oxidation and phenylalanine *p*-hydroxylase system.

Non-Enzymic Reactions of Indoles with Coenzyme I

IN the course of studies of possible enzymically catalysed reactions of coenzyme I (diphosphopyridine nucleotide) with 5-OH-tryptamine (serotonin), tryptamine and tryptophan[1], it was observed that these indoles react non-enzymically with coenzyme I. Thus, when 5-OH-tryptamine was added to a solution of coenzyme I, an intense yellow coloration appeared. Tryptamine and tryptophan also reacted in the same manner, but larger concentrations of the latter substances were required in order to give the same intensity of colour. Spectral characteristics of the coloured materials are shown in Fig. 1.

The intensity of the colour developed (in the region 450–310 mμ) depended on the *p*H, the concentration of coenzyme I and the concentration of the indoles. At very low *p*H values, interaction occurred only to a very limited extent, as judged from the intensity of the colour. In the *p*H range 4–8, differences in the colour intensity of equally concentrated reaction mixtures were very small. At higher *p*H values, and with serotonin as a reactant, the intensity of the colour developed increased rapidly. Although formation of the coenzyme I–tryptamine complex rendered this base soluble even at *p*H values above the *pK'* (about 9·7) for the protonation of its aliphatic amine, it was difficult to carry out quantitative work with tryptamine in this *p*H range (that is, above *p*H 9·0). With respect to the dependence of the colour intensity on the concentration of the reactants, Beer's law was followed within a wide range of variation of the concentration of either reactant. N-methylnicotinamide was found to react in a similar manner as coenzyme I with the indoles.

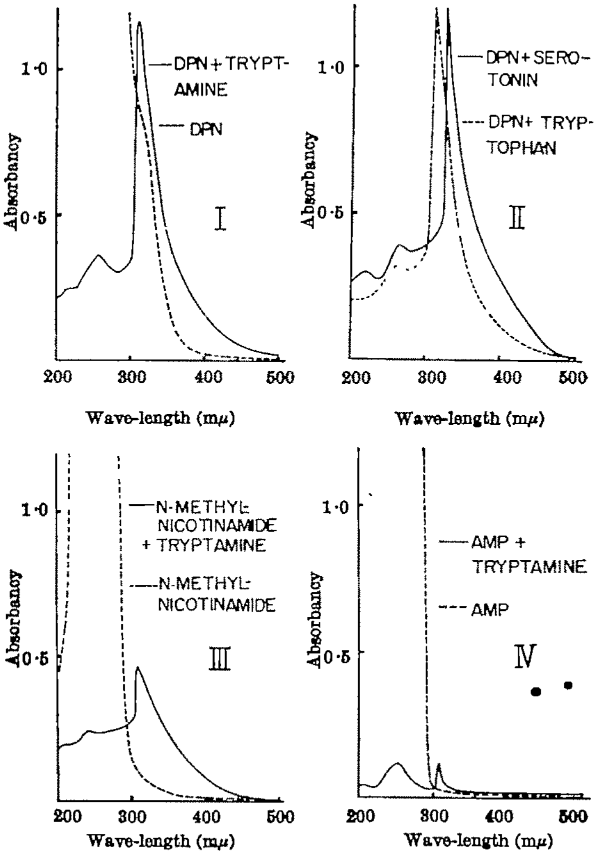

Fig. 1. Interactions of indoles with coenzyme I (DPN) (I and II); N-methyl-nicotinamide (III); and adenosine-5'-phosphate (AMP) (IV). These three compounds were used at concentrations of 5 μmoles per ml. Spectral lines in the absence of indoles correspond to differences (absorbancies) between the absorbance of buffered solutions of the three compounds (experimentals) and the absorbance of the buffer alone (blank). The various indoles were used at concentrations of 20 μmoles per ml. Spectral lines in their presence represent differences (absorbancies) between the absorbance of buffered indole-containing solutions of the three compounds (experimentals) and the absorbance of the respective buffered indole solutions (blanks). All systems were buffered with *tris*-hydroxymethylaminomethane/hydrochloric acid at *p*H 7·8 (400 μmoles per ml.). Absorbancies were taken with a DK_1 Beckman recording spectrophotometer

The experimental evidence indicates that a probable site of reaction of the indole nucleus is the pyrrolic nitrogen in its deprotonated form. The rise of the reactivity of the indoles with increasing *p*H (see above) further supports this view. Apparently, the pyrrolic nitrogen of the indoles acts as a nucleophilic agent, attacking an electrophilic centre in coenzyme I. The participation of the pyridine moiety of coenzyme I in the reaction is indicated by the similar reaction observed with N-methylnicotinamide. In analogy to known reactions of pyridinium structures (for example, coenzyme I) with a number of nucleophilic agents like cyanide[2,3], carbonyl compounds[4], imidazoles[5], etc., the reacting site of the nicotinamide moiety of coenzyme I is probably C4. However, in addition to changes in the visible and near ultra-violet region, the reaction mixtures exhibited also profound changes in the far ultra-violet region of the spectrum. For example, the theoretical absorbancy of a coenzyme I solution containing 5 μmoles per ml. at 260 mμ would be about 90·000 (ref. 6). As shown in Fig. 1, I, the value obtained when a coenzyme I–tryptamine solution was read against an equally concentrated solution of tryptamine was about 0·370, corresponding to a decrease of approximately 243 times. The theoretical absorbance of a tryptamine solution containing 20 µmoles per ml. at 260 mµ would be about 65·000. This creates difficulties in explaining the drop of absorbancy solely on the basis of changes of the indole in the coenzyme I–tryptamine mixture. Since similar changes in the far ultra-violet spectrum are also observed in adenosine-5′-phosphate–tryptamine mixtures (Fig. 1, IV), the adenine moiety of coenzyme I seems to be involved in these interactions.

Attempts to isolate the products (complexes) of these interactions and study their properties are now in progress.

Nonulosaminic Acid (Sialic Acid) in Protists

NONULOSAMINIC ACID[1], a group of simple and substituted 9-carbon sugars containing nitrogen, was thought restricted to mammals until it was found in the supernates of *Escherichia coli* and *Citrobacter freundii* cultures, but not in the supernates of *Salmonella*, *Shigella*, *Pneumococcus* or *Bacillus* cultures[2]. Nonulosaminic acid has now been found in the cells of *E. coli*[3], *Neisseria meningitidis*, *Salmonella dahlem*, and *S. djkarta*[4].

We have examined thirty species of protists for nonulosaminic acid. A minimum of 100 mgm. of cells, dried at 60° C., were hydrolysed in 1 *N* sulphuric acid for 1 hr. at 100° C. and at a concentration of 10 per cent (w/v) : 0·2 ml. of the hydrolysate was analysed for nonulosaminic acid by the Warren method[5]. Presence of nonulosaminic acid was confirmed by descending paper chromatography of the Warren chromophore with 10 per cent ethanol in water as solvent. The interfering deoxyribose chromophore remains at the starting line and fluoresces white with a Wood's lamp ; the nonulosaminic acid chromophore, R_F 0·11, fluoresces pink.

Nonulosaminic acid was found only among the Gram-negative bacteria (Table 1).

From the meagre information available nonulosaminic acid is limited to Gram-negative bacteria.

++, More than 2 per cent nonulosaminic acid ; +, 1–2 per cent ; –, acid not detected.

Gram-negative bacteria share common features besides the Gram reaction ; they elaborate endotoxins causing hæmorrhage in mouse tumours[6] and substances which inhibit agglutination of human blood groups[7]. Should nonulosaminic acid be generally distributed among Gram-negative but not Gram-positive bacteria it would be useful as a phylogenetic marker, especially if it should prove to have a very restricted distribution among Gram-positive bacteria. This is under study.

We thank the U.S. Public Health Service for financial support, Dr. Donald Watson of the Rackham Arthritis Unit, University of Michigan, for a sample of pure nonulosaminic acid, and Drs. K. Eimhjellen, J. Gibson, C. Van Baalen, and W. Vishniac for generous samples of some of the protists studied.

Changes in the Levels of Adenosine Triphosphate and Glycogen in the Liver caused by Protein Administration

DURING a study of the influence of diet on adenosine nucleotide metabolism in the liver of the rat, we have observed that the concentration of adenosine triphosphate in the livers of well-fed animals falls rapidly when they are given a meal of protein. This change

Table 1. Effect of Previous Level of Energy Intake and of Protein Administration on the Concentration of Adenosine Triphosphate and of Glycogen in the Liver of the Rat

Preceding diet	State when killed	Adenosine nucleotides (μmoles/gm. liver)			Glycogen (gm./100 gm. liver)
		Adenosine triphosphate	Adenosine diphosphate	Adenosine monophosphate	
Low energy	Fasting 10 hr.	0·57 ± 0·07	0·92 ± 0·08	2·16 ± 0·07	—
High energy	Fasting 10 hr.	1·65 ± 0·16	0·91 ± 0·08	1·45 ± 0·12	2·3 ± 0·3
High energy	Fed casein 2 hr. before killing	0·45 ± 0·06	0·94 ± 0·16	1·68 ± 0·11	0·6 ± 0·2

On the day of killing, the rats were fed meals of low or high energy content at 9 a.m. and were killed at 7 p.m. Some of the animals on the high energy intake were also fed 2·5 gm. casein at 5 p.m. The adenosine nucleotide data are the means (± *S.E.*) of three experiments, and the glycogen data are the means (± *S.E.*) of six experiments. The adenosine triphosphate concentration for the high energy fasting group was significantly greater than that of the other two groups ($P < 0·01$) and the adenosine monophosphate concentration was significantly lower than that of the low energy group ($P < 0·01$), when analysed by the '*t*' test for differences between groups. The glycogen content of the liver was significantly reduced by protein administration ($P < 0·01$). All other differences were not statistically significant ($P > 0·05$).

is associated with a reduction in liver glycogen content.

Female albino rats weighing approximately 180 gm. were fed twice daily on synthetic diets similar to those used by us in previous experiments[1]. At 9 a.m. they ate 1 gm. of a vitamin–mineral–roughage mixture and 5 gm. of carbohydrate. At 5 p.m. they received 4·2 gm. of a protein–carbohydrate–fat mixture. The total diet of these animals provided 41 kcal./day and in Table 1 they are referred to as the high-energy group. Some animals were fed on the same diet without the carbohydrate in the morning meal. These rats received a total energy intake of 21 kcal./day and are referred to as the low-energy group. The rats rapidly learned to eat these meals promptly and, after a few days, the evening meal was omitted and animals from each group were killed at 7 p.m. in the fasting state, that is, 10 hr. after they had eaten a morning meal which either provided abundant energy as carbohydrate or else contained very little energy. In addition, some of the group on the high-energy intake were given 2·5 gm. of casein (Glaxo), which was made into a paste with 0·1 gm. sodium bicarbonate and was fed 2 hr. before killing. In this way, livers were obtained from three groups of animals: (*a*) a group fasting after a meal low in energy content; (*b*) a group fasting after a meal rich in energy content; (*c*) a group on the higher level of energy intake which were actively absorbing amino-acids from the gut at the time of death.

The livers were analysed for adenosine nucleotides (adenosine tri-, di- and mono-phosphates) by methods described previously[1]. The results (Table 1) confirm our earlier observation[1] that the energy content of the diet has a decisive influence on the concentrations of adenosine nucleotides in the liver. Comparison of the data for the two fasting groups shows that, even although 10 hr. had elapsed since consumption of the last meal, the livers of the rats receiving the higher energy intake had a considerably greater concentration of adenosine triphosphate and a smaller concentration of adenosine monophosphate. However, casein administration 2 hr. before death caused the adenosine triphosphate concentration in the livers of this group to fall to the level observed among animals on the low-energy intake. This was accompanied by a slight increase in adenosine monophosphate concentration which was not statistically significant.

In a separate series of experiments, we observed the effect of these dietary conditions on the glycogen content of the liver. Glycogen was extracted from the liver with 30 per cent potassium hydroxide, precipitated with ethanol and estimated by the anthrone procedure[2]. This showed (Table 1) that rats fasting 10 hr. after receiving the high-energy diet still had a considerable amount of glycogen in their livers, but when animals on this diet received casein 2 hr. before death, a large reduction in liver glycogen content occurred.

Thus the absorption of products of protein digestion causes a marked decrease in the concentration of certain constituents involved in energy metabolism in the liver. These changes occur at an early stage in the absorption process, since it was observed in these experiments that the bulk of the ingested casein was still present in the stomach at the time of killing.

Reversible Transformation of Gelatin to the Collagen Structure

The conversion of soluble collagen (tropocollagen, procollagen, acid-extract collagen) to gelatin has been shown to involve the separation of the three-chain coiled-coil structure of the collagen molecule into single peptide chains[1,2] each having the disordered random-coil configuration. The universal experience with gelatins has been that these disordered chains could not be returned to the complete native collagen structure, although optical rotation, polarized infrared, and wide-angle X-ray diffraction studies of cooled gelatin solutions or gels showed that partial ordering and helical folding of the chains could occur in localized regions[3,4]. The principal factor ruling against the complete reversibility of the collagen–gelatin transition was the requirement for the proper juxtaposition and recoiling of the three complex peptide chains.

Recent studies of the collagen degradation process[5,6] and the structure of high molecular weight gelatins[7,8] gave indirect evidence that some features of the structure, and particularly the interchain cross-linkages present in native insoluble collagen, might be retained in the soluble degradation products. This suggested to us that if the relative peptide chain alignments were retained near the cross-linkage sites, treatments which induced the collagen fold might give rise to ordered collagen-like fibres. We have carried out such experiments and have produced ordered collagen-like fibres.

Our standard for judging whether we had achieved recovery of the long-range collagen structure from gelatin solutions was the preparation of fibrous precipitates that exhibited the cross-striated pattern typical of native collagen fibres when viewed in the electron microscope. The only possibility for the misinterpretation of such observations was that some collagen fibres might have been peptized by the gelatin and carried through the extraction and recovery procedures. We believe that the sequence of experimental steps outlined below eliminated this possibility of misinterpretation of the electron micrographs.

Native bull-hide corium collagen, purified as described previously[9], was extracted in an isoionic suspension (pH ~ 6·0) at 60° for 1 hr. The contraction temperature of this collagen preparation was 55·8–60·6° for individual fibres[6]. The solution of solubilized gelatin (~ 7 per cent)[5] was filtered through sintered glass and then fractionated by an ethanol–sodium chloride coacervation technique[6] into six successive fractions. Any suspended collagen carried along through the filter was precipitated with the first fraction. The remaining fractions were collected and the coacervates were dissolved in warm water (40–45°). The gelatin was recovered from these solutions by precipitation with acetone. These precipitates were washed with cold water, then redissolved at 40°, and reprecipitated with acetone. The third fraction, which contained neither the lowest nor the highest molecular weight material, was chosen for the following recovery experiments.

The dried acetone precipitate was dissolved in 0·1 M potassium chloride at 40° by shaking for 1 hr. The solution, $[\alpha]_D^{40} = -136°$, was clarified by centrifugation in a Spinco preparative ultracentrifuge for 1½ hr. at 144,000g and room temperature. A small, translucent gelatinous sediment was discarded. The clear solution was transferred immediately to a cold room at 4° and was kept there for 20 hr. The solution set to a firm clear gel. The gel was placed in a 40° bath and held there without shaking. Within 12 min., as the gel melted, a fine turbidity developed and within 1 hr. floccules appeared. These were collected by low-speed centrifugation at room temperature. The precipitate was white and fibrous in contrast to the translucent gel obtained in the earlier higher-speed centrifugation. The clear supernatant gelled when cooled to 4° but remained clear when rewarmed.

The fibrous precipitate was examined in an electron microscope and clearly showed (Fig. 1) the typical collagen cross-striations. The fibre width, however, was variable, and the characteristic periodicity averaged about 610 Å. The fibres were readily soluble in 6·0 M urea at room temperature but could be held indefinitely at 40° in water or in dilute salt solution. This behaviour of the heat-precipitable gelatins resembles that of neutral salt-soluble collagen.

The fibres represented about 10 per cent of the protein content of the fraction III solution that remained after the initial high-speed centrifugation. The low negative optical rotation of this solution indicated the absence of the collagen helical structure in the dissolved gelatin molecules.

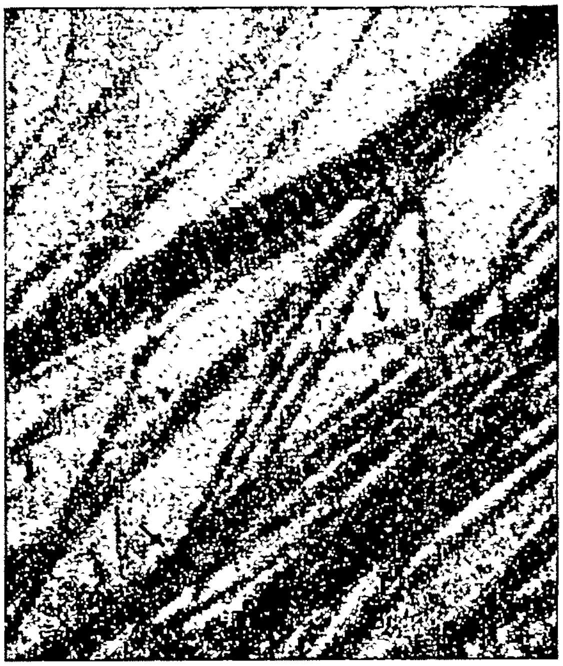

Fig. 1. Electron micrograph of fibres obtained from Fraction III gelatin. Chromium shadowed (× 38,700). The main periodicity is 610 Å., but there is also clearly visible a definite sub-periodicity (arrows) of ~ 210 Å. in the thinner fibrils

Attempts have been made to prepare fibrous precipitates by this and similar procedures with both commercial and other specially prepared gelatins. Only those shown by characterization studies to have the multi-chain structure, and therefore to contain strong interchain cross-linkages, yielded fibrous precipitates. These observations are interpreted as verification of our earlier suggestion that high-molecular weight gelatins are cross-linked networks rather than completely random coils[5,6,8]. Since the chains are held in the proper register whereby they can be re-ordered to the native configuration, the cross-linkages must be inherent in the insoluble collagen and not randomly induced by the degradative treatment.

The quantitative aspects of these experiments are being examined. These, and the necessary characterization studies, will be described in more detail elsewhere.

We are indebted to Dr. L. S. Fosdick of the Northwestern University Dental School for so generously allowing us to use his electron microscope facilities.

PHARMACOLOGY

Milk-ejecting Action of Ergot

It is known that adrenalin inhibits milk ejection[1]. In an attempt to determine whether this inhibition is central or peripheral a series of experiments were performed on rats. The effect of prior administration of ergotamine on the adrenalin-induced black was studied. In the course of this investigation it appeared that ergotamine and ergometrine also had a milk-ejecting action of their own. This property of ergot causing milk ejection does not appear to have been described before.

Milk ejection has been assessed by the increase in weight after suckling of the young rats (8–10 days after birth) separated overnight. Adrenalin as well as atropine and alcohol block the ejection of milk in rats by preventing the release of oxytocin (personal observation). Adrenalin in doses of 1 μgm. and more when administered intraperitoneally always inhibits the milk-ejecting reflex, but when ergotamine ('Gynergen' Sandoz, Ltd.) or ergometrine (Sandoz, Ltd.) is administered to the mother (200–250 gm.) in doses of 50–100 μgm. intraperitoneally half an hour before the administration of adrenalin there is no inhibition of milk ejection. When the lactating mothers were injected with an ergot preparation just prior to suckling the litters gained more weight after suckling than they did normally. The fact that ergometrine also, in addition to ergotamine, has this property of causing milk ejection indicates that ergot does so, not by specifically reversing the action of adrenalin but by itself causing milk ejection. When adrenalin and ergotamine are administered simultaneously to the mother just before suckling there is no inhibition of milk ejection. The action of ergometrine and ergotamine was then studied on six litters where the milk ejection reflex had been blocked by prior administration of atropine (60–120 μgm. intraperitoneally immediately before suckling) and 7·5 per cent alcohol (5 ml./100 gm. body-weight orally 30 min. prior to suckling). It was found that when ergotamine or ergometrine was administered to the mother just prior to suckling neither alcohol nor atropine caused any inhibition of milk ejection. Normally a dose of 3–10 μgm. atropine causes a complete inhibition of milk ejection which can only be reversed by oxytocin. Fig. 1 shows the increase in weight of a litter after suckling when no drug was administered as compared to the increase in weight of the same litter on another day when adrenalin (1 μgm.) and, on another day, adrenalin and ergometrine (50 μgm.) were administered just prior to suckling.

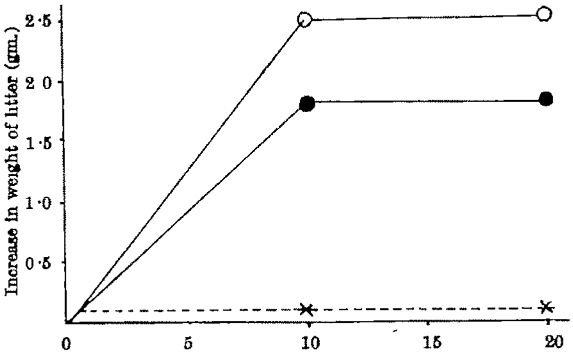

Fig. 1. Milk ejection in unanæsthetized rats. ○, No drug administered; ●, adrenalin (1 μgm.) and ergometrine (50 μgm.) intraperitoneally; ×, adrenalin (1 μgm.) intraperitoneally

The results described in brief indicate that ergot, in addition to its many actions, also causes milk ejection. It is unlikely that ergot causes milk ejection by releasing oxytocin, and we suggest that ergot, when administered to rats, has a direct action on the lactating myoepithelium and causes its contraction. Ergot has for long been known to possess an oxytocic action on the uterus, and it appears to possess another oxytocin-like action causing milk ejection.

Indian Substitutes of Male Fern in Pharmacognosy

Dryopteris filix-mas (L.) Schott, commonly known as the male fern, is a good tænicide and is included in the pharmacopœias of all countries and also in the International Pharmacopœia. India, with her vast resources of drug plants, has many indigenous species of *Dryopteris* growing in the Himalayas, although the true male fern is not indigenous. With the view of finding suitable Indian substitutes of the official drug, phytochemical and pharmacognostical investigations on the following 18 members of the family Aspidiaceae were carried out. *Dryopteris hirtipes* (Bl.) O. Ktze., *D. scotti* (Bedd.) Ching, *D. cochleata* (Don) O. Ktze., *D. barbigera* (Moore) O. Ktze., *D. serratodentata* (Bedd.) Hayata, *D. fibrillosa* (Clarke) Hand-Mzt., *D. rosthernii* (Diels) C. Chr., *D. paleacea* (Don) Hand-Mzt., *D. blanfordii* (Hope) C. Chr., *D. chrysocoma* (Christ) C. Chr., *D. ramosa* (Hope) C. Chr., *D. pulvinulifera* (Bedd.) O. Ktze., *D. splendens* (Hk.) O. Ktze., *D. sparsa* (Don) O. Ktze., *Ctenitis apiciflora* (Wall) Ching, *C. nidus* (Clarke) Ching, *Hypodematium crenatum* (Forsk) Kuhn, *Cyrtomium falcatum* Presl.

Chemical analyses have shown that all the species of *Dryopteris* (with the exception of *D. sparsa*) and both the species of *Ctenitis* contain filicin much above the official requirement (B.P. and U.S.P. require not less than 1·5 per cent of filicin in the crude drug). *Hypodematium* and *Cyrtomium* are practically useless. Of particular interest is the species *D. chrysocoma*, which contains the maximum amount of the active principle (4·3 per cent of filicin in the crude drug). This, together with three other species, namely, *D. ramosa* (3·8 per cent of filicin in the crude drug), *D. barbigera* (2·2 per cent of filicin in the crude drug), and *D. cochleata* (1·8 per cent of filicin in the crude drug), which grow prolifically in a wild state, could be commercially exploited to great advantage.

A valuable field test for species rich in the active principle is found to be a greenish tinge of the cut surface of the rhizome and stipe bases, which colour is retained long after drying. Species poor in this principle either show no colour or turn brown soon after cutting.

An intensive pharmacognostic study has revealed that the species containing oleoresin and filicin invariably show large schizogenously developed cavities within the ground-tissue of the rhizome and the petiole bases. Into these project one to several secretory glands. The species like *D. sparsa*, *Hypodematium crenatum* and *Cyrtomium falcatum* are devoid of these structures, and also the active principle. The secretory glands are of different shapes and sizes in different species but functionally similar. In both species of *Ctenitis* they are elongated cylindrical in contrast to the clavate or pyriform ones in *Dryopteris* species. The former type may probably characterize the genus *Ctenitis* but this requires confirmation by study of more species.

Anatomically, the rhizome and petiole show the usual fern structure. Some species are, however, characterized by the presence of dark patches of sclerenchyma (sclerotic nests) in the ground-tissue of either or both of these structures. These are found to serve as useful criteria for diagnosis. A key based on all the histological characters taken together is being formulated for the differentiation of the species.

PHYSIOLOGY

Korotkov's Sounds: Action of the Heart

Development of work upon Korotkov's sounds, described by me[1], has led to the following explanation of the action of the human heart.

The right and left sides of the heart should each be regarded as the mechanical analogue of a reflex klystron, such as described by Bleaney and Bleaney[2]. The right and left atria on one hand and the pulmonary sinuses and the aortic sinuses on the other constitute cavity resonators wherein contraction and dilatation of the walls and apertures generate force fields through which flows the blood. The action of the left side of the heart will be described in the first instance, although that of the right side is similar.

The function of the left atrium is to set the blood into motion; that of the orifice of the mitral valve is to produce velocity modulation of the stream entering the left ventricle during diastole. The cavity of the ventricle is a drift space in which fast particles of blood travel farther from the mitral valve than slow particles, before being brought to a halt on the completion of ventricular diastole. It is assumed that at the onset of atrial systole, the ring of the mitral valve is of somewhat less diameter than at the end of atrial systole; throughout atrial systole the diameter of the ring increases so that the velocity of the stream decreases.

The blood impinges upon the ventricular wall, by which it is reflected and focused upon the aortic valve. The correct angle of incidence is maintained by the papillary muscles and chordæ tendinæ attached to the mitral valve which guides the flow. At ventricular systole, blood that has travelled farthest is exposed to accelerating force for longer time than blood that has travelled a shorter distance to gain contact with the ventricular wall and, after reflexion, the former is still equivalent to fast particles; the latter to slow. Because of the greater excursion, fast particles are retarded in transit and join slow particles, likewise reflected, which pass through the mitral valve half a period later. This results in alternate attenuation and bunching of the stream flowing through the aortic valve and in the aortic sinuses.

Variations of diameter of the ring of the aortic valve, visible on cardio-angiography, have the effect of accelerating the attenuations and retarding the bunches, this constituting density modulation. In an ordinary fluid, of which the bulk modulus of elasticity is high, very slight variations of density would occur in these circumstances. With blood, however, it is probable that gas bubbles form inside the envelope of the red blood corpuscles, permitting an appreciable 'compressibility'. The pressure, of course, will rise with increase of density and conversely.

More power is taken from the stream during the retardations than is lost during the accelerations, with a gain which is utilized to maintain resonance in the aortic sinuses and a pulsatile flow in the coronary arteries. In addition, there is a shock wave, transmitted by the aorta and coronary arteries, arising from the forces of cavitation in the aortic sinuses.

By analogy from the klystron, the mitral and aortic valves will be out of phase by $(n + \frac{3}{4})$, where n is an integer or zero. Closure of the mitral valve does not coincide with the state of smallest diameter of its orifice, the peculiar structure of the valve making this possible. The aortic valve, on the other hand, closes when the diameter of the ring of the valve is least, accounting for the differing arrangement of the cusps.

It will be seen that the mitral valve is acting as a buncher, the aortic valve and sinuses as a catcher, corresponding to the resonators of the klystron, which are so named. More generally, these functions would appear to be subserved, respectively, by the sinospiral and bulbospiral embryological systems of the heart. The tubular heart, from which the 'reflex heart' develops, is presumably analogous to a straight-through klystron.

The iron-containing substance in cardiac muscle is probably of the nature of a Berthillode compound, for an explanation of which term reference may be made to Partington[3]. On the flow of oxygenated blood through the coronary system, following systole, the lattice-work of the compound increases in diameter as it takes up oxygen, thus increasing the volume of the cavity of the ventricle in an active manner. The shock wave of the second heart sound overcomes thyxotropism in the cardiac musculature, so facilitating ventricular diastole.

Energy from the main blood stream is fed back into this mechanism through the coronary arteries, which also supply the wall of the atrium and the musculature of the mitral orifice, whereby the resonators are coupled.

The two systems will now be assumed to be over-coupled so that the heart is regarded not only as an oscillator but as possessing also the property of self-oscillation. Regeneration is effected through the oxidation of carbohydrate, a process which provides energy to drive the ventricles, or repellors, removing oxygen from the lattice-work which shrinks during systole.

A function of the autonomic nervous supply to the heart is that of tuning the resonators, which is assisted by the apposition of the aortic and mitral valves. In a klystron, separate resonators are difficult to tune: correct phasing is essential in such a device and more easily achieved by the reflex principle.

The right atrium and ventricle behave in a manner similar to the left with the exception that power, taken from the stream, is transmitted solely as a pressure wave by the pulmonary artery. The tricuspid valve acts as a buncher while the pulmonary valve and sinuses act as a catcher, each being in phase and paired to form a set with the corresponding valve of the left side. On each side, the shock wave of the first heart sound overcomes thyxotropism of the atrium.

The wave-mode of the oscillator is stabilized by the conducting system of the heart, which is comparable to the strapping of a magnetron. Mode jumps occur in extrasystole, differing values of n explain the varying grades of heart block but variation of each element of the $(n + \frac{1}{2})$ phase rule is also physiological.

Potential Oscillations in the Lower Olfactory Pathway of the Toad

IN the olfactory bulb of the hedgehog and the rabbit, Adrian[1,2] found that the potential waves evoked by olfactory stimulation take shapes of potential oscillation. It was presumed that the waves were developed by synchronized activity in the dendritic region of the bulb. Later, he[3] recorded the similar potential in the olfactory epithelium of the rabbit, and found that the potential pattern in the epithelium has all the features of that appearing in the bulb. In the experiment, Adrian[3] did not record the potentials in the epithelium and the bulb simultaneously; but from the similarity he presumed that the mechanism which produces the potential oscillation in the bulb originates in the olfactory epithelium. In the olfactory epithelium of the frog, Ottoson[4] found that rhythmic waves sometimes superimpose on the crest of the slow potentials produced by odour stimulation. He presumed that they are identical to the potential oscillations found by Adrian[1–3].

Since the toad (*Bufo vulgaris japonicus*) has long olfactory nerves, potentials can be recorded in the olfactory epithelium, nerve and bulb simultaneously. By olfactory stimulation, potential oscillations appeared in these tissues as well (Fig. 1). Those which appeared in the olfactory nerve and bulb are identical with one another in frequency, phase and shape. Consequently, it is apparent in the toad that the potential oscillations in the bulb originates in, or before, the olfactory nerve. However, the similar potential oscillations have never been found in the olfactory epithelium of the toad. Thus, our finding in the toad partly supports Adrian's assumption. On the other hand, the potential oscillation in the olfactory epithelium of the toad usually appeared superimposed on the slow potential which was reported by Takagi and Shibuya[5–7]. It has higher frequency than the potential oscillations in the nerve and bulb, and is different in shape from the latter ones. Besides, it always began to appear some time after the beginning of the latter ones. It often appeared even after the latter ones had nearly disappeared, when stimulation was very short. In these points, the potential oscillation in the olfactory epithelium of the toad entirely differs from those in the olfactory nerve and bulb. The former oscillation closely resembles the rhythmic wave found by Ottoson[4] in the olfactory epithelium of the frog (*Rana temporaria*). Though we could not find the similar wave in the frog (*Rana nigromaculata*), it is supposed that the rhythmic wave found in *Rana temporaria* is identical to that in the olfactory epithelium of the toad. From these findings in the toad, it is concluded that there are two kinds of potential oscillations in the lower olfactory nervous system, and that they are mutually of indifferent origin and nature.

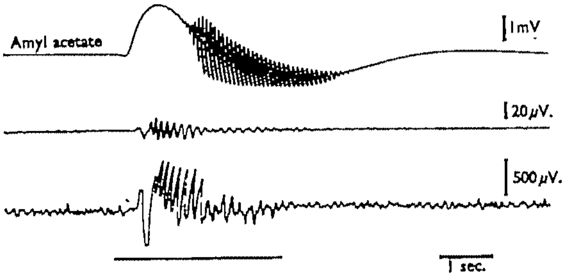

Fig. 1. Two types of potential oscillations. Top, a potential oscillation appearing on the falling phase of the slow potential; middle, a potential oscillation recorded in the olfactory nerve; bottom, a potential oscillation recorded in the olfactory bulb. It is noted that the first half of the potential in the olfactory bulb is identical in frequency, phase and shape with the one in the olfactory nerve, but is entirely different from the one in the olfactory epithelium. The horizontal line on the left below indicates olfactory stimulation

Saliva-Serum Ratios of Tritium after the Administration of Tritiated Water

Taggart and Hytten[1] reported results which indicated that the salivary glands can concentrate deuterium oxide above the level in serum of human subjects. They had administered deuterium oxide orally to normal pregnant women and found, 3 hr. later, saliva–serum ratios ranging from 1·05 to 1·34, and in one subject after 24 hr. they found a ratio of 1·39.

These results have considerable importance as they suggest that human salivary glands can differentiate between deuterium and hydrogen, and it would therefore be of interest to know if a similar effect occurs with tritium. In view of the paucity of information readily available[2] on this subject we decided to estimate the saliva–serum ratios of tritium 3 hr. after the administration of tritiated water in human subjects. The test was performed on 6 physically healthy subjects. 10 ml. of tritiated water containing 500 μc. tritium were given orally immediately before breakfast. 3 hr. later, samples of venous blood and saliva were collected. Water was obtained from serum and saliva by the technique described by Cooper *et al.*[3] and the tritium was estimated in a liquid scintillation counter.

Table 1

Sex	Age	Saliva water (c.p.s.)	Serum water (c.p.s.)	Ratio saliva–serum
F	38	68·6	68·0	1·01
F	45	67·7	67·5	1·00
F	35	54·4	55·6	0·98
M	32	53·8	52·6	1·02
M	36	63·5	64·2	0·99
M	34	59·5	59·3	1·00
Mean		61·25	61·20	1·00

Table 1 shows the results. The saliva–serum ratio at 3 hr. ranged from 0·98 to 1·02 with a mean of 1·00. Thus 3 hr. after its oral administration the tritium in the salivary gland has reached equilibrium with the water in the serum and there is no evidence that the salivary gland is able to concentrate tritium. If the differential concentration of deuterium oxide is related to the atomic weight of deuterium it would seem that this effect should be at least as equally marked with tritium.

Taggart and Hytten raised the possibility that some substance in saliva had distilled across with the water and affected the density of the distillate and thus the estimation of deuterium oxide by the falling drop method. In view of our findings, therefore, it would be useful to have the results of saliva–serum ratios of deuterium oxide estimated by mass spectrometry.

Effect of Thyroxine and 2,4-Dinitrophenol on Levels of Ubiquinone and Ubichromenol in the Rat

THE observation by Aiyar *et al.*[1] that thyrotoxicosis in the rat is accompanied by an increase in liver ubiquinone prompts us to record our own related findings. We have investigated the effect of thyroxine and 2,4-dinitrophenol on both ubiquinone and ubichromenol-levels in the rat, using animals from a stock colony and also from a vitamin-E deficient colony. Female rats were used, aged 3–4 months in one experiment and aged 15 months in another. The animals were divided into groups of six, and test groups received thyroxine, thyroxine and α-tocopheryl acetate, or 2,4-dinitrophenol. After three weeks on test, the rats were killed, and their hearts and livers (each organ pooled with others from the same group) were analysed for ubiquinone and ubichromenol by the method of Diplock *et al.*[2].

Table 1. FEMALE RATS OF THE NORWEGIAN HOODED STRAIN WERE USED IN GROUPS OF SIX

In Exp. 1, the rats were 3–4 months old; in Exp. 2, 15 months old. The supplements were: Exp. 1, thyroxine, 2,4-dinitrophenol and α-tocopheryl acetate all at 25 μgm./gm. of diet; Exp. 2, thyroxine 5 mgm. and 2,4-dinitrophenol 1·25 mgm. divided into bi-weekly doses intraperitoneally

Exp.	Group treatment	Ubiquinone (μgm./gm.)		Ubichromenol (μgm./gm.)	
		Heart	Liver	Heart	Liver
1	Adequate vit. E control	205	127	4·4	80·6
	Adequate vit. E + thyroxine	179	342	8·4	119
	E-def. control	149	162	4·0	46·8
	E-def. + thyroxine	180	227	9·4	83·0
	E-def. + thyroxine + α-tocopheryl acetate	199	235	9·9	82·0
	E-def. + 2,4-dinitrophenol	241	182	25·5	69·5
2	E.-def. control	159	96	15·7	34·1
	E-def. + thyroxine	141	482	14·3	148
	E-def. + 2,4-dinitrophenol	143	114	14·4	47·4

The results are given in Table 1, the figures for ubiquinone and ubichromenol representing the total isoprenologue content[3] in each case.

In both rats receiving adequate vitamin E and those deficient in this vitamin, thyroxine produced large increases in the ubiquinone- and ubichromenol-levels in the liver, these increases being particularly marked in the older group of vitamin-E deficient rats. Indeed, the levels in the livers of the latter animals are considerably higher than any others so far observed by us in the course of several hundred tissue analyses. The effects of thyroxine on levels in the heart were less marked generally. The further supplementation of the thyroxine group with α-tocopheryl acetate produced no noticeable effects in these experiments. When 2,4-dinitrophenol was given to vitamin-E deficient rats in an amount equivalent to thyroxine on a molecular basis, little effect was observed; but, when larger, nearly toxic doses of 2,4-dinitrophenol were given, a sharp increase in ubiquinone and ubichromenol occurred in the heart, although the liver was relatively unaffected.

Although 2,4-dinitrophenol and thyroxine are both agents that uncouple oxidative phosphorylation, their mode of action is different. It is possible that the above effects on ubiquinone- and ubichromenol-levels *in vivo* may be related to this uncoupling activity and that the differences observed may reflect the difference in mode of action; alternatively, they may be caused simply by a differing uptake of thyroxine and 2,4-dinitrophenol by the heart and the liver. Whether the increases in ubiquinone and ubichromenol are due to enhanced synthesis or to less-efficient utilization of these lipids cannot be deduced from these experiments, but the results here are qualitatively different from those of other experiments on the specific influence of vitamin-E on the levels of ubiquinone in the rat, in which a direct effect on synthesis is more clearly indicated.

Influence of Temperature upon Blood Coagulation in a Cold- and a Warm-blooded Animal

THE influence of change of temperature upon the speed of blood clotting in warm-blooded animals is well recognized. Indeed, the fact that human plasma at 0° C. does not clot for several hours is utilized in some investigations in coagulation research.

If a similar depression of blood coagulation at low temperatures occurred in cold-blooded animals this would tend to make them unusually vulnerable to trauma during some part of their lives. This consideration led us to compare the influence of temperature on the clotting mechanism of a warm- and a cold-blooded animal.

Because of its ready availability, human blood was compared with that of the South African clawed toad *Xenopus laevis*. Human blood was collected by venepuncture and toad blood was obtained from the heart after the animal had been anæsthetized with ether. Considerable difficulty was at first experienced in obtaining adequate unclotted samples by methods involving direct cardiac puncture. To overcome this, the heart was exposed by a central skin excision, division of the pectoral girdle and opening of the pericardium. The animal was then placed on a wire netting (approximately 1 cm.^{2} network) with the heart dependent between the wires. In this way approximately 3 ml. could be collected into an underlying vessel within a few seconds of a deep scalpel incision into the ventricle. The contamination by tissue juices, although present, is probably minimal under these conditions and the sample appears preferable to that obtained after a lengthy and technically difficult cardiac puncture technique. The blood from three toads was pooled to make a single specimen.

All samples were collected in graduated siliconed centrifuge tubes with 3·8 per cent of sodium citrate in a proportion of nine parts of blood to one part of citrate solution.

The thromboplastin preparations were made from emulsified human brain and emulsified toad brain and spinal cord. The dilutions were adjusted to give a satisfactory one-stage prothrombin time with human and toad plasma respectively. The thromboplastin time (one-stage 'prothrombin' time) and the calcium clotting time estimations were performed as recommended by Biggs and Macfarlane[1], but in the latter test citrated whole blood was substituted for citrated plasma.

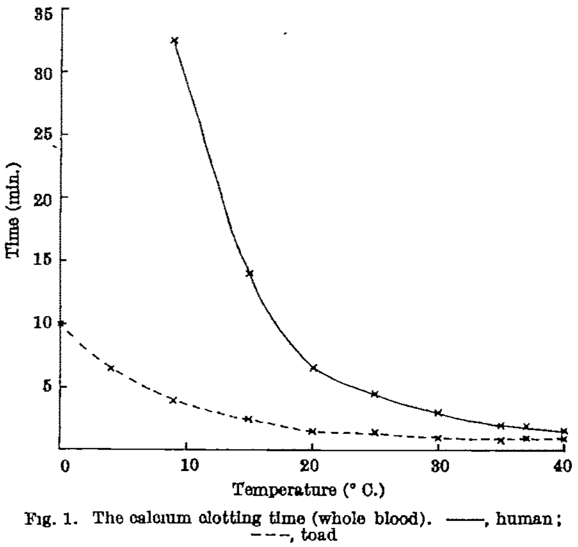

Fig. 1. The calcium clotting time (whole blood). ——, human; – – –, toad

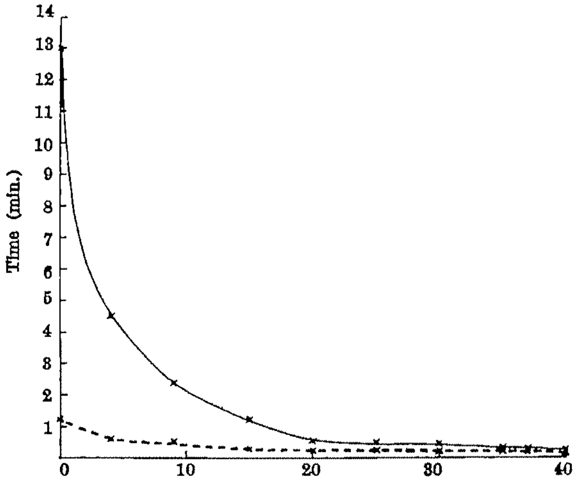

Fig. 2. Thromboplastin time (one-stage 'prothrombin' time). ——, human; – – –, toad

The results are shown in Figs. 1 and 2.

A determination of calcium clotting time was used in preference to one of whole-blood clotting time, because the latter would have required several fresh samples of blood, needing more than a single animal to cover the complete range of temperature being investigated. It therefore appeared desirable to test the clotting time of a single pooled citrated sample obtained from three animals after recalcifying at various temperatures.

In order to keep the platelet activity of the specimens as close to physiological conditions as possible, citrated whole blood rather than plasma was used in the estimations of the clotting time.

Quick[2] showed that tissue thromboplastin of a reptile (turtle) showed species specificity, when mixed with the plasma of warm-blooded animals. This specificity has been demonstrated with the amphibian used in this investigation. The thromboplastin times of human or toad plasma were therefore compared using human and toad brain emulsions respectively. Owing to the small size of the toad brain, the spinal cord was also included in the preparations.

From a comparison of the two curves in Fig. 1 it can be seen that the toad-clotting mechanism appears well adapted for functioning at low temperatures. Fig. 2 shows the influence of temperature on the thromboplastin time, which does not involve certain clotting factors, such as hæmophilic globulin, which are needed for active intrinsic thromboplastin formation. As with the recalcified whole blood clotting time the thromboplastin time in the cold-blooded animal appears comparatively unaffected by a temperature lowered below 10° C.

Blood Glucose in Crayfishes in Relation to Moult and Handling

DURING a recent investigation of the physiology of excretion in the crayfish[1], it was discovered that significant differences in blood glucose-levels existed between intermoult (stage *C*) and premoult (stage *D*) specimens of *Pacifastacus leniusculus* (Dana) (Table 1). The moult stage was determined by a modification of the method of Drach[2]. The crayfishes were kept in a water-bath at 16° C. in which they had been unsegregated and unfed for periods of one to two weeks. Blood glucose was determined by the glucose oxidase (enzymatic) method of Saifer and Gerstenfeld[3] (for details of experimental procedure, see Riegel and Kirschner, ref. 1).

Table 1. BLOOD GLUCOSE-LEVELS OF INTERMOULT (*C*) AND PREMOULT (*D*) MALE *Pacifastacus leniusculus*. DIFFERENCES ARE STATISTICALLY VERY SIGNIFICANT ($t = 3{\cdot}06$; $P = < 1$ PER CENT)

Moult stage	*C*	*D*
Number	10	9
Average blood glucose (mgm. per cent)	21	48
Range	(5–39)	(18–91)
Standard error	3·3	7·7

Glucose proved to be a highly mobile substance in crayfish blood ; injected glucose disappeared rapidly. Handling of crayfishes (for example, injection of materials, and especially withdrawal of blood samples at frequent intervals) commonly resulted in a spontaneous rise in blood glucose-levels, a prolonged cessation or marked decrease in urine production, and in many cases the abnormal appearance of glucose in the urine.

The results of determinations of normal blood glucose-levels of *C*- and *D*-stage crayfishes agree with those of Renaud[4], who measured the reducing value of the blood of *Cancer pagurus*. However, Scheer[5] found no difference in blood carbohydrate-level between late *C*- and early *D*-stage *Carcinides* (= *Carcinus*) *maenas*. Similarly, McWhinnie and Scheer[6] found that the blood glucose-levels of *Hemigrapsus nudus* reached their maximum during the intermoult (*C*) stage of the moult-cycle and actually declined during the premoult (*D*) stage. McWhinnie and Scheer determined glucose by a method similar in most respects to that used in the present work. They found that glucose comprised less than 20 per cent of the total 'blood sugar' value determined by other less-specific methods.

The reasons for the spontaneous rise in blood glucose of handled crayfishes are obscure. It seems reasonable to assume that handling placed the crayfishes under stress. Since an elevation of blood glucose-levels is a common stress phenomenon seen in vertebrates, it is possible that a similar stress–blood glucose relationship exists in the crayfish. This explanation would fail, if the view of Scheer[7], that glucose is not utilized as a substrate for oxidative metabolism in Crustacea, is accepted. However, more recent evidence (ref. 8 and Scheer, B. T., personal communication) indicates that glucose is, in fact, utilized for oxidative metabolism in crustaceans ; at least, according to Scheer[7], in those crustaceans that undergo a period of dormancy during their moult cycle (anecdysis). The crayfish is an anecdytic form, as are the crabs, *Hemigrapsus nudus* and *Carcinides maenas*.

The complete cessation or marked decrease in urine production and the glucosuria of crayfishes that were handled[1] is suggestive of a hormonal effect. For example, the stoppage or decrease in urine production commonly was maintained for 20 hr. or more during the experimental periods—long after handling had ceased. Further, it was only after 20 hr. that glucosuria occurred. It is well known that the sinus glands of Crustacea contain a diabetogenic hormone, which is reported to be responsible for most of the hyperglycæmic effects seen in those animals[9]. The diabetogenic hormone conceivably could be responsible for the hyperglycæmia and possibly the glucosuria of handled crayfishes. Further, it is possible that it, or some as yet unknown hormone fraction, has an antidiuretic effect in the crayfish.

Membrane Potential Changes associated with Stimulation of Smooth Muscle by Adrenalin

THE smooth muscle of the taenia coli of the guinea pig is contracted by acetylcholine and is relaxed by adrenalin. It has been shown that acetylcholine contraction is associated with depolarization of the muscle membrane and initiation or increase in spike activity[1,2]. Adrenalin relaxation is associated with hyperpolarization of the membrane and inhibition of spike activity[1,3].

The smooth muscle of the muscularis mucosæ (dog) is contracted by both acetylcholine and adrenalin[4]. It was of interest, therefore, to observe whether adrenalin contraction of this muscle was associated with hyperpolarization or depolarization.

Membrane potential changes of muscularis mucosæ (pig œsophagus) in the presence of adrenalin and acetylcholine were measured by the sucrose gap technique[5]. Fig. 1 shows that contraction by adrenalin as well as by acetylcholine was associated with depolarization and initiation of spike activity.

This result supports the view that drugs act via a membrane system, where depolarization and initiation of spike activity result in contraction, and hyperpolarization in relaxation. It is unlikely that adrenalin acts in two completely different ways on the muscle membranes of the taenia coli and muscularis mucosæ. It is more likely that adrenalin acts in the same way on two muscles which differ in internal/external ion distribution and/or in membrane permeability properties. Comparison of the morphological features

and electrical properties of these two muscles revealed no qualitative differences[6,7]. Experiments designed to detect differences in ion distribution, permeability and electrogenic sodium pump activity[3] are in progress.

Accumulation of Substrate by Isolated Rat Diaphragm: a Possible Mechanism for the Anti-Inflammatory Action of Corticosteroids

ADRENALECTOMY enhances, and adrenal cortical hormone depresses, the incorporation of carbon-14 from amino-acids, and from amino-acid precursors, into the protein of isolated rat diaphragm[1,2]. These changes are, at least in part, the result of a direct effect on protein biosynthesis[1,3]. Whether corticosteroids also effect protein synthesis indirectly by influencing amino-acid transport and accumulation is not known. The possibility was tested by measuring the penetration and accumulation of [1-^{14}C-]-amino*iso*butyric acid[4], a non-utilizable amino-acid analogue, and of the utilizable amino-acids [U-^{14}C] L-phenylalanine and [U-^{14}C] L-lysine, by 'intact' diaphragms[5] isolated from normal, adrenalectomized, and cortisone-treated rats.

Table 1. EFFECT OF ADRENALECTOMY AND CORTISONE ON THE ACCUMULATION OF CARBON-14 LABELLED SUBSTRATE BY ISOLATED 'INTACT' RAT DIAPHRAGM

Substrate added to the medium	Counts/min./ml. intracellular water / Counts/min./ml. incubation medium		
	Normal	Adrenal-ectomized	Cortisone
[1-^{14}C]-amino*iso*-butyric acid	1·41 ± 0·061 (6)*	1·35 ± 0·046 (6)	0·72 ± 0·021 (6) (P < 0·001)
[U-^{14}C]-L-phenyl-alanine	2·51 ± 0·120 (6)	2·41 ± 0·149 (6)	1·79 ± 0·052 (6) (P < 0·001)
[U-^{14}C]-L-lysine	1·95 ± 0·059 (6)	1·88 ± 0·055 (6)	0·92 ± 0·030 (6) (P < 0·001)
[2-Ring-^{14}C] histamine dihydro-chloride	3·88 ± 0·125 (6)	3·69 ± 0·375 (6)	2·83 ± 0·096 (6) (P < 0·001)

Diaphragms from normal, adrenalectomized (4 days) and cortisone-treated (2 mgm./day for 4 days) rats were incubated with shaking for 2 hr. at 37° in 5 ml. Krebs–Henseleit bicarbonate buffer. Concentration of substances used were: [1-^{14}C]-amino*iso*butyric acid, $1·37 \times 10^{-4}$ M; L-phenylalanine, $4·9 \times 10^{-5}$ M; L-lysine, $6·55 \times 10^{-5}$ M; histamine, 1×10^{-4} M. The radioactivity added was, in each experiment, 0·5 μc./ml. Accumulation of soluble radioactivity was determined by extracting diaphragm with 10 ml. of 1 per cent trichloracetic acid at 100° for 5 min. Aliquots of the soluble extract and of the incubation medium were diluted, plated and assayed with a gas-flow Geiger counter. The results are expressed as the ratio of counts/min./ml. intracellular water (assumed to be 75 per cent of wet weight) to counts/min./ml. incubation medium; a ratio greater than one indicates intracellular concentration against a gradient. The value of P for a difference which is significant is given in brackets.

* Mean ± *S.E.* of mean; number of observations in parenthesis.

Cortisone significantly depressed accumulation in skeletal muscle of [1-^{14}C]-amino*iso*butyric acid and of L-phenylalanine and L-lysine; adrenalectomy was without effect on this process (Table 1). It is concluded that increased protein biosynthesis after adrenalectomy is not due to stimulation of amino-acid penetration; decreased accumulation could contribute to the depression in protein synthesis after cortisone.

The decrease in amino-acid penetration after cortisone has another and possibly more important implication, namely, that the mechanism of corticosteroid protection against inflammation and allergy may involve exclusion from cells of inciting humoral substances, similar in structure to the amino-acids, as for example histamine. This possibility was tested. Cortisone decreased accumulation of carbon-14 histamine by isolated muscle (Table 1). The biochemical basis of the anti-inflammatory and anti-allergic action of corticosteroids may be a decrease in the penetration into cells of a local humoral substance (histamine or like histamine) which in turn serves as the stimulus for tissue changes in inflammation and allergy.

This investigation was aided in part by a grant (*A*–1653) from the National Institutes of Health, and by the Wallace C. and Clara A. Abbott Memorial Fund of the University of Chicago.

IMMUNOLOGY

A Possible Basis for Immunological Tolerance

THE following hypothesis is based on the possibility that, although the mechanism for the entrance of macromolecules into the cell may be the relatively non-specific phenomenon of pinocytosis, the mechanisms for secreting materials out of the cell may be specific. These unknown (probably active) transport mechanisms will, for ease in referring to them, be called 'secretases', by analogy to the bacterial permeases, which are concerned with entry rather than exit mechanisms[1]. Simple diffusion would account for only a small part of the macromolecular traffic in either direction across the membrane, since most of the 'pores' or holes in the cell membrane would be too small to allow passage of the large protein molecules.

The very young or embryonic animal is generally incapable of giving an immune response or forming antibodies ; at what particular stage it does acquire the ability to respond depends upon the species of animal. The degree of relationship of the antigen to native components of the animal may also be important. In the developing animal the cells of the future globulin- and antibody-synthesizing system are in the process of rapid division and differentiation. In some unknown manner cells acquire the ability to produce globulins of many different configurations. It is suggested here that a mechanism (the 'secretase') is induced in these cells to secrete the synthesized serum protein into the serum. Secretases would also be induced to act on the materials produced by the other cells, and brought into any given cell by non-selective processes.

The number of different secretases need not be impossibly large ; there may well be, for example, a few relatively unchanging regions common to many different globulin molecules. Other regions of the globulin molecules would be more variable[2] and would account for the many different antibody specificities. Porter[3] has evidence that the γ-globulin molecule consists of three parts : fraction III is apparently identical in all gamma-globulin molecules, and fractions I and II contain the antibody-combining sites. The types of secretases inducible would be under genetic control, and only those secretases for which there were genetic information available would be inducible. The inducibility of un-induced secretases would be lost or inhibited in the mature animal, although the fact that X-irradiation[4] or treatment with 6-mercaptopurine[5] can restore the ability to acquire tolerance suggests that this type of differentiation is not irreversible for the organism as a whole.

According to this hypothesis, antigen injected into the normal animal would be collected in cells by non-specific mechanisms, and, not being able to get out, would be metabolized. Humphrey[6] has suggested that foreign materials in the circulation are removed from the tissue fluids by the mechanisms that deal with similar native materials. In those cells where molecules with a configuration complementary to the antigen (antibodies, usually γ-globulins) were being produced, combination between the two would occur intracellularly. The resulting complex would then be broken down, and the increase in metabolites might be the stimulus that causes these cells to grow, accelerate their production of antibodies, and proliferate. Talmage's observation[7] that the greater the binding of the antigen to the antibody, the greater the degree of stimulation of antibody synthesis, would be explained by a facilitated breakdown of the antigen–antibody complex in those cells where the affinity of the antigen for the antibody was strongest. Cinader and Pearce[8] observe that "the difference between the half life of H.A. [human albumin] in normal and in tolerant animals may indicate the possible existence of a specific process of elimination which acts before the final rapid elimination of antigen by antibody begins. This process may be abolished by injection of antigen immediately after birth".

Presence of the antigen during the critical induction period would result in the induction of a secretase for the antigen, if the genetic information were available. Continued presence of the antigen in the tissues would be required to maintain the secretase ; if antigen were lost from the tissues the secretase would gradually be diluted out and the animal would lose its tolerance. The tolerant animal could not form antibody against the tolerated antigen, or against its own serum proteins, because the secretase would prevent these molecules from accumulating in the cells in amount sufficient to stimulate detectable antibody production.

Humphrey[6] has shown that in at least one case homologous protein persists intact within katabolizing cells for only a very short period of time. One might predict, on the basis of this hypothesis, that antigen would be eliminated from the *serum* of non-tolerant animals, prior to their immune response, at a faster rate than it would be eliminated from the serum of tolerant animals. Cinader and Pearce[8] found that non-tolerant animals could eliminate antigen from the serum at a faster rate than tolerant animals ; however, work by Denhardt and Owen[9] with a small number of rabbits indicated that tolerant animals could eliminate antigen from their sera at a greater rate than non-tolerant animals. Further study of this problem is highly desirable.

In conclusion, it is realized that tolerance may be equally well accounted for in terms of induction of a specific enzyme katabolizing the antigen ; perhaps what is required is a synthesis of these two points of view. The 'secretase' may be considered as the hypothetical 'recognition unit' postulated by Burnet and Fenner[10].

The encouragement and expert guidance of Dr. Ray Owen and the helpful suggestions of Prof. Peter Medawar are gratefully acknowledged.

HÆMATOLOGY

A New Electrophoretic Medium and its Application to the Resolution of Human Hæmoglobin Variants

SEVERAL techniques for the analysis of protein mixtures by either zone electrophoresis on inert media[1] or chromatography on ion-exchange cellulose derivatives have been described[2,3]. Greater scope and versatility should result if the supporting medium used for zone electrophoresis itself ionizes. In standard gel-electrophoresis techniques, ion transport takes place almost exclusively through the interstitial solution. The incorporation of ion-exchange groups into a gel superimposes a selectivity effect, the migration of the ions being retarded to a varying extent depending on their affinity for the exchanger. Attempts to use ion-exchange cellulose papers in this way have so far been unsuccessful. It is, however, also possible to prepare these cellulose derivatives in gel form. Electrophoresis on such a continuous-phase ion-exchange medium has not been reported hitherto. This communication is a preliminary report on the combination of electrophoretic and ion-exchange techniques applied to the separation of human hæmoglobin variants, using carboxymethyl cellulose gel as the supporting medium.

The sodium counter-ion form of the weakly acidic cation exchanger, carboxymethyl cellulose, is soluble in water at degrees of substitution above about 0·3, while below 0·15 the exchanger is fibrous though swollen. Between these limits it is in gel form, and by suitably modifying the standard preparative technique a range of gels can be made (Jakubovic, A. O., unpublished results). Certain aspects of the fibrous exchanger have been described[2,5], and it has also been applied to the chromatographic separation of hæmoglobins by Huisman and his colleagues[3].

One batch of gel (supplied by W. and R. Balston, Ltd.), carboxymethyl cellulose of 0·18 substitution, having a cation-exchange capacity of 1·05 m.equiv./gm. dry, and swollen to 90 per cent water content, was used throughout the experiments. After purification by dialysis in de-ionized water, the gel was dialysed with the appropriate buffer—sodium phosphate of 0·17–0·04 M sodium ion concentration—and placed in a suitable 'Perspex' boat. The final pH in the gel was 6·7. Electrophoresis was carried out overnight. The naturally occurring hæmoglobin combinations used in the experiments described were hæmoglobins A, SC, AS, AF (thalassæmia major, HbF = 75 per cent) and AJ.

The hæmoglobins invariably migrated to the cathode, the rate of migration increasing with the sodium ion concentration. At the highest concentrations used, the hæmoglobins moved through the gel rapidly, showing only slight separation (Fig. 1a). On lowering the sodium concentration they moved more slowly, migrating at various rates, but always in the order hæmoglobin A followed by hæmoglobin S and F close together and then C; at the lowest sodium concentration used they remained close to the origin (Fig. 1b). By varying the sodium ion concentration, either the hæmoglobin S to C or the hæmoglobin A to S gap could be magnified (Fig. 2a and b). The best overall separation was achieved with a sodium ion concentration of 0·07 M (Fig. 2c). This figure also shows clear separation of hæmoglobin A from F.

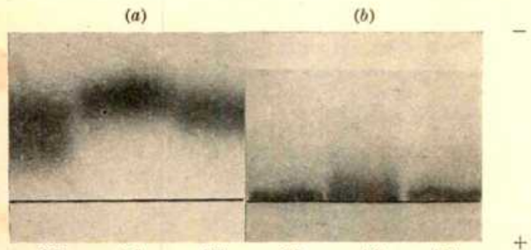

Fig. 1. Electrophoresis of human hæmoglobin variants on carboxymethyl cellulose gel at the extremes of sodium concentrations used: (a) 0·17 M; (b) 0·04 M

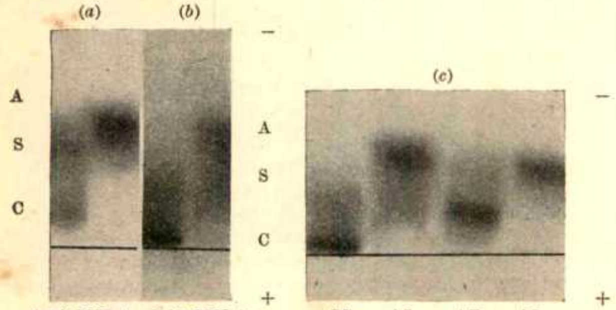

Fig. 2. Electrophoresis of human hæmoglobin variants on carboxymethyl cellulose gel. (a and b) Effect of variation of the sodium ion concentration on the separation of hæmoglobins A, S and C. (c) Overall separation achieved at 0·07 M sodium concentration, including separation of hæmoglobins A and F

Table 1

* Huehns, E. R., Flynn, F. V., Butler, E. A., and Shooter, E. M. (unpublished work).

In Table 1 the order of migration in starch-gel electrophoresis, carboxymethyl cellulose gel electrophoresis and chromatographic elution from fibrous carboxymethyl cellulose are compared. Under the carboxymethyl cellulose gel electrophoretic conditions used, the ion-exchange effect was predominant. From Table 1 it can be seen that hæmoglobins C, S and F are strongly held by the gel, but in the case of hæmoglobin J the ion-exchange and electrophoretic effects seem to be balanced and therefore hæmoglobins A and J did not separate.

It would, however, be possible to change the pH of electrophoresis in such a way that the charge on the protein was reversed, and the migration would then be unaffected by the exchange groups of the gel. The influence of the latter depends on the concentration and ionization of the carboxyl groups. The concentration can be varied by changes in degree of substitution of the cellulose and swelling, the ionization by varying the pH and ionic concentration of the ambient electrolyte. Only the last has been utilized here. The effect of varying the capacity and swelling of the exchanger gel and the pH of electrophoresis, as well as the wider utilization of this new method of gel-phase ion-exchange electrophoresis, is being investigated.

We wish to thank Dr. E. M. Shooter for helpful advice and discussion. The work was carried out during the tenure by one of us (E. R. H.) of a Beit Memorial Fellowship.

PATHOLOGY

Chronic Aortitis in the California Sea-lion, *Zalophus californianus*

During a long-term study on the general biology of the California sea-lion, *Zalophus californianus* (Lesson), it became evident that degenerative diseases associated with ageing are very common in this species. Therefore, a study of the heart and aorta was undertaken.

Circulatory disease in captive pinnipeds has been extensively studied by Fox[1] over a number of years. His findings included arteriosclerosis with typical medial involvement as well as myocarditis. Of the ten pathological specimens he found during this work, no indication was given of the genus and species involved; all animals were grouped under the order Pinnipedia.

The present study deals with lesions in the aorta of three mature bull sea-lions and is the first report of such pathology in this species to be found in a wild population. The hearts of seventy animals of both sexes were taken at random for study from a total collection of some two hundred specimens; these were obtained over the past two and a half years from islands off the coast of Baja California, Mexico. The collection area ranged from Los Coronados Islands (lat., 32° 26′ N.; long., 117° 16′ W.) to Cabo San Lucas, the extreme southern tip of Baja California (lat. 22° 45′ N.; long. 110° 00′ W.). All three of the abnormal individuals were secured on Los Coronados Islands, where most of the males were collected.

As soon as possible after killing, the hearts were removed leaving several inches of aorta attached: after rinsing in water, the tissue was preserved in 10 per cent formalin for later examination. The aortas were screened for visible lesions. Of the three specimens exhibiting gross pathology, two were sent to two separate laboratories for section and independent histopathological study; the third was retained and examined by us. The three diagnoses were identical. The sections were stained with hæmatoxylin and eosin. No gross myocardial disease was evident in any case.

Using the Lieberman–Burchard reaction on ether extracts of the finely ground material, samples from the pathological areas revealed a considerably higher cholesterol content than samples of the tissue from apparently normal adjacent regions.

Grossly, the intimal surface of the arteries contained numerous punctate elevations which, in the most extreme case, resembled tree bark. Approximately 10 per cent of the intimal surface was involved and the affected areas ranged in width from 0·1 to 1·5 cm.

Microscopically, the sections of aorta revealed extensive active aortitis, while other areas showed healing. The intima itself was not involved; rather there was, in the foci of the active areas, an extensive inflammatory reaction in the media, extending from the subintima to the adventitia. The disease process involved destruction of elastic tissue about the blood vessels and an infiltration of plasma cells, macrophages and lymphocytes. A secondary fibrosis in the subintimal areas overlaid the zones of aortitis. The healed areas contained abnormally large blood vessels surrounded by small amounts of scar tissue.

In many respects the condition found in these sea-lions resembles the aortic lesions found in chronic human syphilis, although the etiology of the disease in these animals is unknown.

The work was accomplished while the senior author served as a research assistant of the Institute of Marine Resources at the University of California and while the junior author held a fellowship-grant from the San Diego County Heart Association, to which grateful acknowledgment is made. The work was made possible by the effective co-operation of the Mexican Government.

Our sincere thanks are due to Dr. Lewis A. Palmer, La Jolla Clinical Laboratory, and Dr. Findlay E. Russell, College of Medical Evangelists, Los Angeles, for their kindness in the preparation and diagnosis of the sections.

BIOLOGY

Inactivation by Visible Light of Yeast sensitized by a Nucleic Acid Fluorochrome

Precise and reproducible survival curves have previously been obtained for haploid and diploid yeast irradiated with X-rays and with ultra-violet light[1,2]. Similar curves have now been obtained for the inactivation by visible light of yeast cells sensitized with the fluorescent diaminoacridine dye, acridine orange (3,6-*bis*-dimethylaminoacridine).

Cells of a haploid (*SC*–7) and a diploid (*SC*–6) strain of the yeast, *Saccharomyces cerevisiae*, were used in resting condition following seven days growth on potato dextrose agar at room temperature. Survival was measured by colony count on agar plates after three days incubation at 30° C. in the dark. The light source was a General Electric *R*–52 750-watt flood-lamp filtered to remove wave-lengths greater than 6000 Å. and less than 4100 Å.; the incident flux at the level of the samples was approximately 10^5 erg/cm.^{2}/sec. 20 min. before irradiation, highly purified acridine orange was added to a suspension of 10^6 cells/ml. in *p*H 7 phosphate buffer to make a final dye concentration of 1 : 200,000 or $1{\cdot}8 \times 10^{-5}$ *M*. Details of the dye purification process and of experimental technique will be given elsewhere. All operations were performed under red light. Neither visible irradiation in the absence of dye nor the presence of dye without irradiation produced inactivation.

Typical visible light inactivation curves for haploid and diploid yeast are shown in Fig. 1. These curves exhibit high reproducibility except for the resistant 'tail' appearing at low diploid survival. (Such variable tails are also found for X-ray and ultra-violet inactivation.) These curves are similar to those obtained for ultra-violet inactivation[2] in that they are multi-component types of low 'hitness' and that the diploid is more resistant than the haploid.

These similarities between the visible and the ultra-violet inactivation curves tempt one to conclude that visible light inactivates some of the same

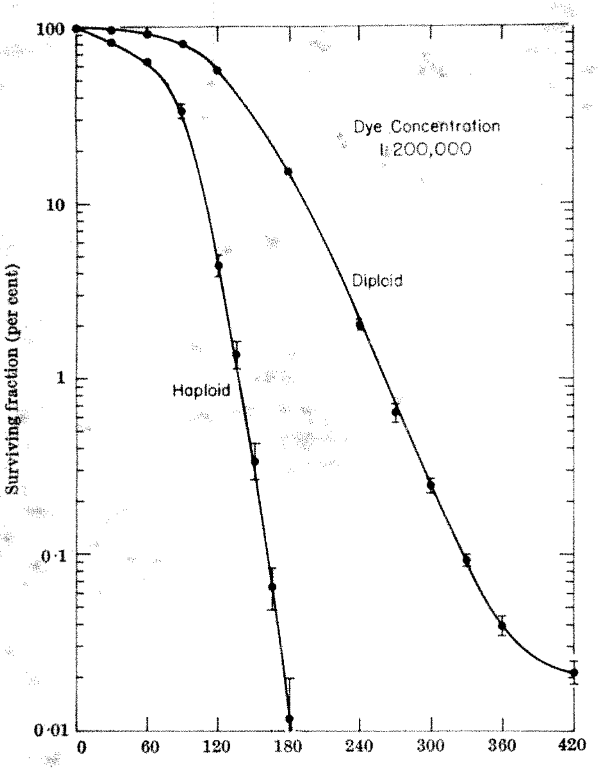

Fig. 1

sites that are sensitive to ultra-violet and that at least part of the damage can be explained by the replica diploid model[3,4] which has been invoked to account, in part, for the well-known difference in sensitivity between haploid and diploid yeast for ultra-violet and for X-rays. However, the equality of the limiting slopes of the haploid and diploid curves, which would be required if all the damage resulted from a replica diploid mechanism, is lacking. To examine further the nature of the visible light inactivation, perhaps the best approach (made feasible by the reproducibility of the survival curves) is that of additivity experiments in which doses of X-rays, ultra-violet and visible light are combined. From a series of such experiments, we have concluded that there is indeed considerable overlap among the targets and sites sensitive to these different radiations and that the difference in visible light sensitivity between the haploid and diploid strains can be explained, in part, on the basis of the replica diploid model. These experiments will be reported elsewhere.

These curves are of interest for several reasons. There has recently been much interest in the application of diaminoacridine dyes, particularly acridine orange, as stains in fluorescence microscopy[5]. These dyes allow one, on the basis of the different colours of the emitted light, to localize and distinguish structures containing ribonucleic and deoxyribonucleic acids within a cell. Most of this work has been done on fixed preparations with impure dye. Although the dyes will also stain the living cell, there are reports of deleterious effects on populations of micro-organisms and on cells in tissue culture[6-9]. It is likely, especially in view of the strong fluorescence of these dyes, that much of the damage reported in living preparations is caused by photodynamic action or other photoinactivation resulting from light absorbed by the bound dye, as is the case with the yeast inactivation reported above. Indeed, regeneration of liver tissue within the living rat has been shown to occur in the presence of proflavin[10]. It is then possible that under appropriate conditions these dyes can be used for non-injurious staining of many kinds of living cells. We have found that this is in fact the case for low concentrations of dye and that if suitable precautions are taken against the action of visible light (that is, by growing cultures in the dark and working by red light), such diverse materials as yeast, *Escherichia coli* and human liver cells in culture not only withstand exposure to acridine orange while in the resting state but also multiply indefinitely in concentrations of dye sufficient to permit observation of actively dividing cells with a sensitive fluorescence microscope (unpublished work).

By detailed analysis of inactivation curves, it may be possible to identify the specific intracellular sites to which the dye molecules are actually bound *in vivo*. Further, if most of the dye contained in the cell is bound specifically to nucleic acid and if the photodamage results from action upon these molecules alone, then there may be available a method for destroying part or all of a nucleic acid molecule without the concomitant effects upon protein which result when ultra-violet radiation is used for this purpose.

This investigation was aided by research grant *C*–2739 from the National Cancer Institute of the United States Public Health Service. One of us (D. F.) was supported by a National Science Foundation Predoctoral Fellowship.

Pure Culture of the Trichomycete, *Amoebidium parasiticum*

The Trichomycetes as defined by Duboscq *et al.*[1] include four orders of little-known fungi. Common characteristics of this class include a polarized thallus of limited growth, a basal holdfast, and association with various arthropods, usually as endocommensals in the digestive tract.

Previous work on the Trichomycetes has raised some interesting problems for both the botanist and zoologist. There are repeated suggestions in the literature that the resistant stages of the Trichomycetes are induced by host moulting. If this should be the case, it immediately brings to mind the close relation existing between the wood-roach flagellates and their host during the moulting period[2]. Numerous questions on host specificity, host relations and nutrition await further investigation. A possible answer to some of these questions can be obtained through experimental approaches utilizing pure (axenic) cultures. Previous investigators have failed to isolate any member of the Trichomycetes in pure culture. Lichtwardt[3] and I (unpublished work), utilizing varied methods and conditions, failed to culture members of the Eccrinales.

The discovery of a large population of various *Cladocera* infected with *Amoebidium parasiticum* (see Fig. 1, left) has made possible cultural attempts with this Trichomycete. Heavily infected animals were dissected in sterile diluted pond water. This dissection resulted in the release of numerous endospores into the water. The endospores were retrieved with a fine capillary pipette and carried through three washes of sterile water. The spores were then transferred in a drop of water to dilute (0·1 per cent) tryptone agar plates and streaked with a sterile glass rod. Colonies of *Amoebidium parasiticum*, which were free from bacteria, were observed after three days (see Fig. 1*b*). They were then transferred to 1 ml. of water at the base of a tryptone agar slant and to a tryptone–glucose broth. Good growth occurred on both of these media and purity was maintained. (Composition of broth: 5 gm. tryptone, 3 gm. glucose per litre. Total phosphate, 0·003 *M*; inorganic constituents as indicated by Machlis[4].)

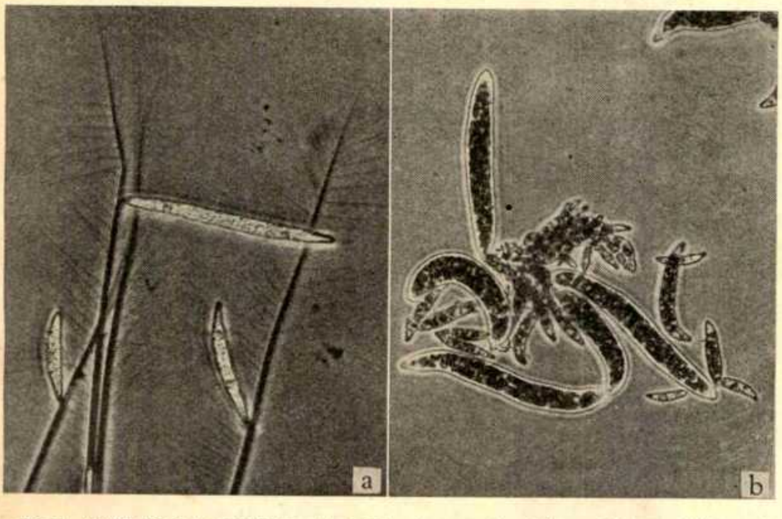

Fig. 1. (*a*) Thalli of *A. parasiticum* attached to plumose setæ of *Simocephalus* sp. (Cladocera). × 350. (*b*) Thalli of *A. parasiticum* grown in tryptone–glucose broth. × 170

Reproduction in pure culture is by endospores and factors causing amœba formation have not yet been determined. As *Amoebidium parasiticum* is usually an ectocommensal and exhibits a rather low host specificity it is perhaps not surprising that it was obtained in pure culture. The techniques utilized are fairly standard[5] and have been used by Emerson in culturing *Oedogoniomyces lymnaeae* and by me in culturing *Harpochytrium hedenii*. Both these fungi have unbranched thalli with basal holdfasts. However, their vegetative reproduction is by uniflagellate zoospores and they are not associated with animal hosts. It is believed that a comparative study using pure cultures of *Amoebidium*, *Oedogoniomyces* and *Harpochytrium* will yield information on the biology and relations of these interesting organisms.

Furunculosis in Salmon Kelts

According to the report of the Furunculosis Committee[1], this disease is most common among salmonids during the summer, when river-levels are low and when the water temperature lies within the range 55–66° F. The final report of this Committee[1] does, however, mention the occurrence of this disease in spawning or spawned salmon "in at least two districts in Scotland", but no further details are given.

Large numbers of salmon die in the rivers each year after spawning. The cause of this mortality, which is heavier among males than among females, is unknown, but it is commonly supposed to be the outcome of a period in fresh water without food and of the strain imposed by movement upstream followed by spawning.

During the autumn of 1958, salmon were impounded in the upper reaches of a Scottish river for stripping. Three of these fish died before stripping, and it was later found that they had died from furunculosis; more of the fish died after stripping, again, as was afterwards learned, from furunculosis. These results suggested either that these fish had become infected during their period of impoundment or that furunculosis was a more common cause of death in kelts than had been supposed. To examine the latter possibility, dead or dying kelts were collected from the lower reaches of the river in question and from three other Scottish rivers. In all, 96 kelts were examined and, of these, 85 had furunculosis.

River-levels were very low during November and December 1958, and these unusual conditions may have contributed to this result, in that fish were more closely congregated than usual, offering favourable conditions for the spread of disease, and dead fish were more easily seen and removed. Observations on the occurrence of furunculosis in kelts were therefore again made in 1959. Most of the rivers were in spate during the spawning season of that year, so that recovery of dead kelts was more difficult. To date, 24 kelts have been received from 5 rivers, and 9 of the kelts had furunculosis. This incidence of furunculosis in kelts was not confined to Scottish rivers, as during 1959, 14 salmon kelts were examined in England and Wales. I am indebted to Mr. F. T. K. Pentelow, chief salmon and fresh-water fisheries officer, for the information that 11 of these were suffering from furunculosis.

Whether or not the incidence of furunculosis among kelts in the Scottish rivers in 1958 was unusually high, the two sets of results suggest that the normal incidence of this disease in kelts is high enough to warrant further investigation. As this might be an important factor in the spread of the disease, these observations will be continued.

Genetical and Biochemical Studies of the Immobilization Antigens of *Paramecium aurelia*

HIGHLY purified preparations of the immobilization antigens of *Paramecium aurelia*, about which extensive genetic studies have been described previously[1], are now known to consist largely of protein (ref. 2 and unpublished work by J. O. B.). With the aim of obtaining information on genetically controlled protein variations, we have made a preliminary study of the physicochemical properties of some of these antigens, using various stocks of *P. aurelia* (variety 1). The antigens studied are denoted 60D, 90D, 103D, 33D, 60G, 60T. Formation of the first four is governed by a series of alleles denoted D^{60}, D^{90}, etc., and of the fifth by a non-allelic gene G^{60} in conjunction with a different cytoplasmic state. The type 60T is produced in conjunction with a third cytoplasmic state; but the genic basis of this type has not been investigated.

The immunological relationships between the different types of antigen appeared to vary according to the kind of test which was performed. By the immobilization test very little cross-reaction was found when any heterologous combination of the above-mentioned antigens and the various antisera was made. Other tests, however (absorption of immobilizing antibodies by whole *Paramecia* or migration of precipitin bands in agar-gel diffusion experiments), showed that the four D antigens are immunologically related to each other, and are unrelated to the 60G type (J. O. B., unpublished work).

Electrophoretic behaviour of the antigens was studied on starch-gel at *p*H 9·6 by a modification of the method of Smithies[4]. A gradient of 30–40 V. per cm. was found to be necessary to get appreciable movement of the antigens and the runs usually lasted 6–8 hr. After this time a slice of the gel was removed and stained with nigrosin, showing the presence of a single band of protein near the origin on the anode side. All other mobile proteins had passed into the anodic buffer vessel by this time. Correspondence of the stained band with antigen was shown by taking a parallel slice of gel and testing the eluate obtained from it for specific serum-blocking activity.

In this way the electrophoretic mobilities of the antigens were compared and it was found that type 60G moved toward the anode significantly more slowly than any of the D types (see Fig. 1), and type 60T was the fastest. All four (allelic) D types were apparently identical in mobility under these conditions.

Some of the antigens were also compared in regard to their adsorption–desorption behaviour on a column of calcium phosphate, using the technique of Tiselius *et al.*[5]. Partially purified preparations of various antigens were applied to the column and elution was then carried out with phosphate buffer at *p*H 6·8, starting with an ionic strength of 0·001 *M* and increasing stepwise to 0·05 *M*. Protein in the samples of eluate was measured spectrophotometrically by ultra-violet absorption at 280 mμ and antigenic activity assayed by serum-blocking. It was found that antigen 60G was eluted by buffer at an ionic strength of 0·005 *M*, 60D and 60T at 0·01 *M* and 90D at 0·05 *M*. When two antigens (60D and 90D) were mixed together and chromatographed on calcium phosphate, two peaks of protein—each containing only one antigen—were obtained at positions on the elution diagram corresponding exactly to those found when the two antigens were chromatographed separately.

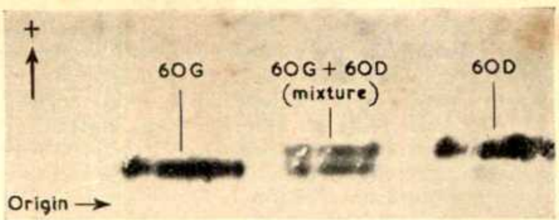

Fig. 1. Photograph of starch-gel slice containing three samples of antigen, stained with nigrosin after 4 hr. electrophoresis at 30 V. per cm., *p*H 9·6

We therefore conclude that the electrophoretic comparisons of the different antigens studied to some extent parallel the immunological and genetical relationships: antigens which are unrelated immunologically and controlled by genes at different loci (for example, the G and D types) differ electrophoretically; antigens which are immunologically closely related and controlled by allelic genes at a single locus do not show electrophoretic differences under the conditions chosen, but do differ in regard to their adsorption–desorption behaviour on calcium phosphate.

More detailed accounts of the work referred to here will be published elsewhere. Thanks are due to the Medical Research Council for a grant supporting this work.

BACTERIOLOGY

Mechanism of Immunity in Hæmorrhagic Septicæmia

HÆMORRHAGIC septicæmia of cattle and buffaloes caused by *Pasteurella multocida* type I kills many thousands of animals in Asia each year. It is possible to immunize against the disease effectively with improved vaccines, and in addition 5–10 per cent of animals possess a naturally acquired immunity. Both kinds of immune animals have in their sera circulating antibodies which are detectable by the passive mouse protection test. Hitherto, it has been difficult to find whether these protective antibodies operated by a bactericidal or an opsonizing mechanism. Experiments using cultured bacteria, even those from primary plates sown with infected blood, showed no significant differences between known positive and negative sera in the bactericidal test of Muschel and Treffers[1], or in phagocytosis tests in roller tubes using heparinized or citrated blood.

Recent experiments in Australia and Thailand using pasteurellas grown *in vivo* in cattle and buffaloes give clear results in both bactericidal and phagocytosis tests. In 25 buffaloes and 6 cattle, complete correlation was obtained in mouse protection, serum bactericidal, opsonizing tests and direct challenge of the donor animals by subcutaneous injection of 1000 *LD* of the pasteurella. Twenty-six were positive to all tests and survived; five were negative to all tests and succumbed. In the latter group an occasional leucocyte was found containing a single pasteurella, whereas in the positives nearly every polymorphonuclear cell in the smears from roller tubes contained several pasteurellas. The bactericidal effect was measured by the ability of fresh sera in dilution of 1 ml. in 10 ml. broth to prolong the lag phase of the inoculum of pasteurellas introduced in 0·01 ml. infected serum. When growth occurred after the period of inhibition there was no agglutination except in the very strongly reacting sera. Mice inoculated with 0·1-ml. samples withdrawn 30 min. after the positive tests were set up survived, whereas those inoculated from negative tests died. This indicates a bactericidal effect on the inoculum rather than a temporary agglutinating action; the amount of serum in the inoculum was only one-tenth of a mouse protective dose in a conventional passive immunizing test. Parallel tests conducted with cultured pasteurellas were uniformly negative for bactericidal action, and phagocytosis was approximately equal in both immune and control bloods.

Extraction by 2·5 per cent aqueous solution of sodium chloride of dried cultivated pasteurellas yielded 0·5 per cent by weight of a ketose-containing polysaccharide which is disposed mostly at the surface of the small capsules. This substance was not detectable in pasteurellas grown *in vivo*[2]. This is the only difference known at present between the two kinds of bacteria which might account for their different reaction in the bactericidal tests.

Nitrogen Fixation in Extracts of *Azotobacter vinelandii*

IT is well established that soil micro-organisms, including species of *Azotobacter* and *Clostridia*, fix atmospheric nitrogen. Although several attempts have been made to demonstrate the incorporation of nitrogen-15 into extracts of these micro-organisms the results at best have been variable and of doubtful significance[1]. Protoplasts, prepared from *Azotobacter* by careful lysis of the cells with lysozyme, incorporated only small amounts of nitrogen-15, namely, an enrichment of 0·04 atom per cent excess[2]. We have recently succeeded in preparing cell-free extracts from *Azotobacter vinelandii*, either by treating the cells with lysozyme or with the ultrasonic probe, which will incorporate nitrogen-15 at a measurable rate. The cells must, however, be disrupted in the culture medium in which they were grown.

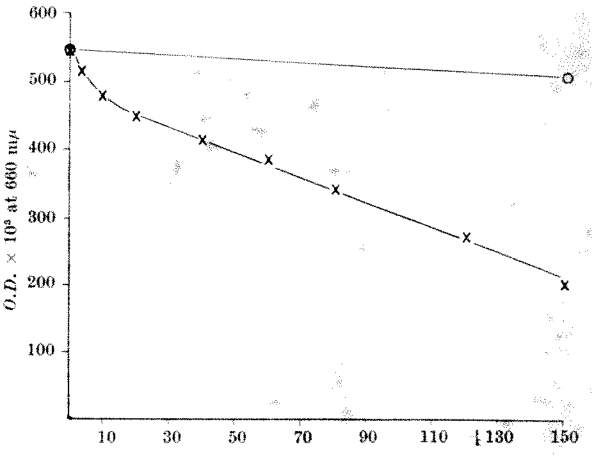

Fig. 1. Effect of lysozyme on the disruption of cells of *Azotobacter vinelandii* measured in 1-cm. cells at 660 mμ in a spectrophotometer. Assay system given in text. ○—○, No lysozyme; ×—×, lysozyme added

Azotobacter vinelandii (*O* strain) was kindly supplied by Dr. R. Burris and Dr. P. Wilson, Wisconsin University, Madison. The bacteria grown in 500 ml. of Burk's nitrogen-free medium[3] (*p*H 7·2) in litre flasks were well aerated in shake culture with sterile air. After 24-hr. growth, when the optical density readings of 3 ml. aliquots of the medium in 1 cm. cells were between 0·5 and 0·8, the cells were disrupted either with lysozyme or, alternatively, with an ultrasonic probe. The lysozyme treatment was a modification of Repaske's method[4] for lysing Gram-negative bacteria—50 ml. culture solution containing the cells was put in a 100 ml. conical flask, the *p*H adjusted to 8·0 with 0·01 *N* sodium hydroxide and the following reagents added; 5 ml. 0·1 *M* sodium pyrophosphate (*p*H 8·0), 5 ml. disodium versenate (0·16 mgm./ml.) and 5 ml. egg-white lysozyme (0·2 mgm./ml.). The decrease in optical density of the suspension was followed at 660 mμ in a 1-cm. spectrophotometer cell. The results in Fig. 1 show that at *p*H 8·0 almost complete lysis of the cells was achieved within 2 hr. The *p*H of the lysate was then adjusted to 7·2 with 0·01 *N* hydrochloric acid since nitrogen fixation in whole cells is maximal at this value.

The ultrasonic treatment with the Mullard probe (20 kc./s.) was as follows: 30 ml. culture medium containing the cells was put into a double-wall glass vessel (40 ml. capacity) which was kept cool by circulating iced water through the jacket. The contents were agitated with a magnetic stirrer and the cells were subjected to ultrasonic treatment for 15 min.

Cell-free extracts from either treatment were prepared by centrifuging at 25,000*g* for 30 min. in a refrigerated centrifuge at 4° C. Microscopic examination confirmed the complete absence of whole cells from these extracts.

Whole cells or extracts of *Azotobacter* were exposed to nitrogen-15 in 25 ml. sterilized Erlenmeyer flasks fitted with Thunberg type stoppers so that the contents, usually 10 ml., could be evacuated to 0·1 mm. mercury before introducing the following gas mixture : 30 per cent nitrogen : 30 per cent oxygen : 40 per cent helium. The nitrogen was 30 per cent enriched with nitrogen-15. The vessels were sealed and put on a reciprocator for 18 hr. (80 oscillations/min.) at 30° C. The samples were digested with 3-ml. sulphuric acid (analytical reagent) s.g. 1·84, 0·5 gm. catalyst mixture (4 gm. mercuric oxide : 50 gm. potassium sulphate) in micro-Kjeldahl flasks for 6 hr. A suitable aliquot containing between 30 and 400 μgm. total nitrogen, as determined in the Markham apparatus, was distilled into 5 ml. 0·07 *N* sulphuric acid (analytical reagent) and the volume reduced to approximately 1 ml. in a boiling-tube before transferring it into one arm of a Rittenberg tube. The enrichment of nitrogen-15 in the samples was determined by the method of Sims and Cocking[5].

Table 1. FIXATION OF NITROGEN-15 IN EXTRACTS OF *Azotobacter vinelandii*

Atom percentage nitrogen-15 excess

A. Extracts prepared by lysozyme treatment

	(1) Whole cells	(2) Lysis of cells with lysozyme. Supernatant solution used after centrifuging at 25,000*g* for 30 min.	(3) Boiled supernatant solution from (2)	(4) Supernatant solution from (2) treated with 10 per cent w/v trichloracetic acid
Exp. 1	4·00	0·22	0	0
Exp. 2	3·54	0·54	0	0

B. Extracts prepared by ultrasonic treatment

(1) Whole cells	(2) Ultrasonic treatment of cells (15 min.)	(3) Supernatant solution after centrifuging at 25,000*g* for 30 min.	(4) Boiled supernatant solution from (2)
2·73	2·54	0·385	0

The results in Table 1 show that the cell-free extracts of *Azotobacter* prepared by either method incorporate appreciable amounts of the stable isotope. The ultrasonic treatment of the cells did not appear to affect the nitrogen-fixing mechanism since enrichment of the isotope in the homogenate was similar to that of whole cells. Even after high-speed centrifugation the incorporation of the tracer into the cell-free extracts, although reduced, was quite substantial. Work is now in progress to determine the mechanism of nitrogen fixation in the cell-free preparations and, in particular, the nature of the contributory factors in the culture medium in which the organism was grown.

The mass spectrometer measurements were made for us at the Physical Chemistry Department of this University through the courtesy of Dr. W. J. Dunning and later by Dr. D. H. Tomlin, Physics Department, University of Reading. We acknowledge with thanks the help received from the two Departments.

Simplified Bulk Growth of *Vibrio fœtus*

THE cultivation of *Vibrio fœtus* in quantity, for antigen production, is generally regarded as rather difficult and costly. Commonly employed culture media are semi-solid 'Thiol' (Difco) and *Brucella* broth ('Albimi'), both containing 0·1 per cent agar.

A recent paper[1] summarizes much of present knowledge on the subject, and describes the adaptation of a previously published method[2] for *Pasteurella multocida*, using a special liquid medium. Apart from a French reference[3] we have found no mention in the literature of the employment of ordinary (nutrient) agar for the growth of *V. fœtus*, and no mention at all of the use of broth.

The nature of vaginal 'exudates' and other specimens from which we recovered *V. fœtus* led us to suspect that this organism thrived best in the presence of abundant moisture. We found that it grew more readily and luxuriantly on solid media, for example, when the condensation water had not been removed by drying (for example, during prior incubation as a sterility check, which we omit). Serial subculturing on blood-agar plates was usually then successful.

We originally used nutrient agar (equal parts meat extract[4] and Martin's peptone[5] plus 1·5 per cent agar) treated in this way for the production of antigen, setting it in 8 oz. 'medicine' bottles lying flat and distributing over the surface about 20 × 0·08 ml. heaps of young *V. fœtus* culture in semi-solid agar (equal parts meat extract and Martin's peptone + 0·1 per cent agar). After incubation in less than 10 per cent carbon dioxide the growth was harvested by washing with formol–saline, physiological saline or broth. The last two have the advantage that a second crop can be harvested after simply re-incubating the original agar bottles without further sowing.

In semi-solid agar, in which the inoculum remained near the surface, rich growth occurred in tubes down to about 1 cm. below the surface under 10 per cent carbon dioxide and in zones at various depths in air. Increased depth of the growth disks below the surface is associated with reduction in catalase activity, which usually reappears on subculture under 10 per cent carbon dioxide.

For bulk culture, the semi-solid agar was placed in wide, flat-bottomed glass vessels to form a shallow layer the depth of which approximated that to which *V. fœtus* grew in tubes of such agar when incubated under 10 per cent carbon dioxide, namely, 1–2 cm. After incubation at 37° C. for 2–4 days, harvesting was carried out by adding 10 volumes of saline for each volume of medium present.

The agar was separated by centrifugation for 15 min. at 500*g* and the bacteria sedimented by a second centrifugation for 15 min. at 3,000*g* in an angle head. Failure to remove the agar results in difficulties in reading the vaginal mucus agglutination test.

The cells were washed by resuspending and centrifuging three times with formol–saline (physiological saline containing 0·3 per cent formalin), *p*H 7, and then resuspended, in formol–saline containing 0·5 per cent phenol, to the opacity desired for the vaginal mucus agglutination test.

It was then found that *V. fœtus* could be grown in nutrient broth (equal parts meat extract and Martin's peptone) without the addition of agar. In vertical tubes the inoculum sank to the bottom and no growth occurred ; but when the broth was dispensed in a shallow layer (1–2 cm.) in wide, flat-bottomed vessels, as just described for semi-solid agar, good growth resulted. Greater depth of medium could probably be used if mechanical agitation were employed. Harvesting and washing procedures were as for other bacteria grown in broth.

After two days incubation in an atmosphere of 10 per cent carbon dioxide we were usually able to prepare a volume of antigen suspension (of opacity 2 on the Burroughs Wellcome scale) a little greater than that of the broth originally inoculated. Incubation for four days generally yields about double the volume, and even five days incubation does not seem to impair the specificity of the antigen.

To date six strains of *V. fœtus* (the English 'Longsdon' and '1980', and four local field strains isolated at Glenfield) have been found to grow well in both media. Each of the four local strains did so immediately after primary isolation on blood agar plates. At present semi-solid agar is used for stock cultures and broth for antigen production.

We are grateful to Mr. J. C. Keast, director of veterinary research, New South Wales Department of Agriculture, for his encouragement and interest in this work, and to Dr. B. P. Setchell, also of this Station, for helpful advice in the preparation of notes for publication.

GENETICS

Inheritance of Asymmetry in a Water-boatman (*Krizousacorixa femorata*)

ASYMMETRY of the abdominal segments in the corixid males is a regular occurrence with the sense of asymmetry, dextral or sinistral, regularly uniform intraspecifically. One finds among the males no intermediate forms, for all the asymmetrical structures of a dextral male are perfect mirror-images of those in a sinistral male and vice versa. More particularly, the sex-limited structures are confined to the body wall, and more precisely, to the last six segments where the exoskeleton and musculature display an asymmetrical pattern, emphasized by an oval black body (the strigil) and a curved genital capsule. In the dextral male the strigil is limited to the right margin of the sixth segment and the genital capsule is directed to the right. These asymmetrical structures are, of course, mirror-images of those in a sinistral male, while in the females bilateral symmetry prevails. Instances of *situs inversus*[1] are rare.

At Lake Zumpango, near Mexico City, I discovered an unusually high frequency of *situs inversus* in a large population of *K. femorata*, or water-boatman. In a sample of 650 males, 475 were dextral and 175 sinistral. Though previous investigators have reported the phenomenon of *situs inversus* in this corixid, I have not found any published account of the inheritance of dextro-sinistral asymmetry in this or any other species of corixid.

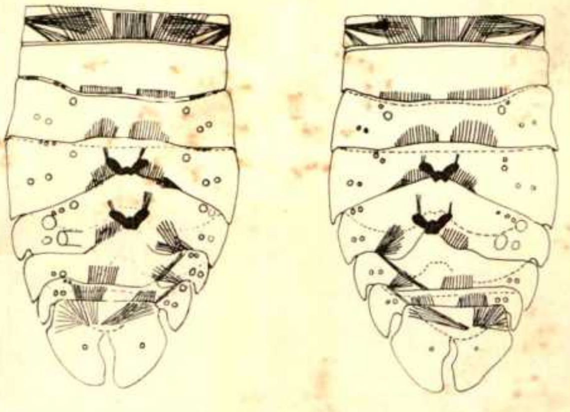

Fig. 1. Ventral view of the abdominal exoskeleton and musculature in asymmetrical males, dextral and sinistral, of *K. femorata*, Guer.

In elucidating the mode of inheritance by means of breeding experiments, single-pair matings in various combinations were made in the laboratory. An all-dextral male line of some ten generations was established. Attempts to produce an all-sinistral line, however, resulted in families containing dextral and sinistral males in different proportions. The results from three single-pair matings of a sinistral male and a virgin female are shown in Table 1, suggesting a 2 : 1, 1 : 1, and 1 : 2 ratio.

Table 1. PROGENIES FROM CROSSES BETWEEN SINISTRAL MALES AND VIRGIN FEMALES

Family 1	52 sinistral ♂♂	49 dextral ♂♂	62♀♀
Family 2	52 sinistral ♂♂	25 dextral ♂♂	90♀♀
Family 3	17 sinistral ♂♂	36 dextral ♂♂	50♀♀

A sequence of experimental matings of dextral and sinistral lines was carried out and the segregation ratios analysed; these will be published in full detail elsewhere. From the results, however, one can conclude *ex hypothesi* that the inheritance of the polymorphic characteristic of asymmetry depends upon an allelomorphic series of three genes, D, D^s, and d, of which D (dextrality) is dominant to D^s (sinistrality), which in turn is dominant to d (dextrality). The intermediate member of the series is lethal as a homozygote.

I am grateful to Sir Ronald Fisher for his direction of this work.

Triploid Rat Embryos and Other Chromosomal Deviants after Colchicine Treatment and Polyspermy

Austin and Braden[1] have shown in their classic paper on polyspermy in the rat that dispermy leads to a triploid fertilized egg and that such an egg may cleave normally up to at least the eight-cell stage. These conclusions have been confirmed by the recent investigations of one of us[2]. However, Braden and Austin[3] found no instance of triploidy among rats born from delayed mated females in spite of the presence of about 9 per cent dispermic eggs at fertilization stages.

The fate of heteroploid mammalian embryos coming from sources other than polyspermy has mostly been

Table 1. EFFECTS OF INTRAPERITONEAL INJECTIONS OF COLCHICINE ON FERTILIZATION IN THE RAT

Interval mating-injection	Dose (mgm./100 gm. body-weight)	No. of females	Penetrated eggs	Polyspermic eggs	Eggs with suppressed second polar body	Androgenetic eggs	Eggs with subnuclei
2 hr.	0·025–0·05	13	111	7 (6·3%)	42 (38%)	1 (0·9%)	16 (14%)
2½ hr.	0·05	6	45	0	5 (11%)	17* (38%)	8 (18%)

* Includes four possible androgenetic eggs at the 2- to 3-cell stage.

Table 2. CHROMOSOME CLASSES OF 9–15 DAYS OLD RAT EMBRYOS AFTER DIFFERENT TREATMENTS TO INDUCE HETEROPLOIDY

Age of embryos (days)	Group	No. of pregnant females	No. of embryos	Classified as			
				Diploid	Triploid	Mosaic	Without mitoses
8–12	Colchicine	14	63	42	2	13	4
	'polyspermy'	12	130	115	8	6	1
13–15	Colchicine	5	22	14	0	1	7
	'polyspermy'	9	89	84	0	2	3

examined in the mouse[4]. Some spontaneous triploid and mosaic embryos were recovered in 'silver' females up to 9½-days gestation. But triploids were absent in the offspring of 'silver' mice (Beatty, R. A., personal communication). No heteroploid adult was observed either in the offspring of colchicine-treated mice[5]. It would seem, therefore, that most, if not all, heteroploid (triploid) mouse embryos die some time between mid-term and parturition.

In the present communication we report attempts to induce experimentally polyspermy and other types of heteroploidy in the rat. Parallel with this work, the fate of heteroploid rat embryos has been studied by chromosomal examination.

Adult female rats of the Wistar *CF*, Long-Evans, and Sherman strains were used, all mated with Wistar *CF* males towards the end of œstrus. It is known[6] that if mating is not allowed until after ovulation, sperm penetration in the rat begins about 2–4 hr. after copulation and then is completed, in any one rat, in 1–2 hr. The eggs were examined under the phase-contrast microscope in the living state and, in some cases, after acetocarmine staining under the coverslip.

In an attempt to induce polyspermy, eight females of each of the three strains used were subjected to a moderate hyperthermia for 3 hr. after mating. The body-temperatures were maintained at 40–41° C. by keeping the rats in a box heated at 35–36° C. The incidence of polyspermic (dispermic) eggs reached 8–10 per cent in the Sherman and Long-Evans strains but only 3·5 per cent in the Wistar *CF* strain.

In order to inhibit the second polar division, Wistar *CF* females were injected intraperitoneally with colchicine after mating. In earlier work[7], intraperitoneal injections of 0·05–0·1 mgm. colchicine per 100 gm. body-weight, 1–2 hr. after delayed matings, caused suppression of the second polar body in about 70 per cent of the eggs. Other abnormalities were: eggs with a single (presumably male) pronucleus and those with subnuclei in place of the female pronucleus. Our results are shown in Table 1.

It appears that the frequency of the different anomalies depends closely on the time of application. If the drug is applied at 2 hr. after mating, the second polar body is suppressed in many eggs; on the other hand, androgenesis is the principal anomaly at 2½ hr. In the latter case the second 'polar body' is formed

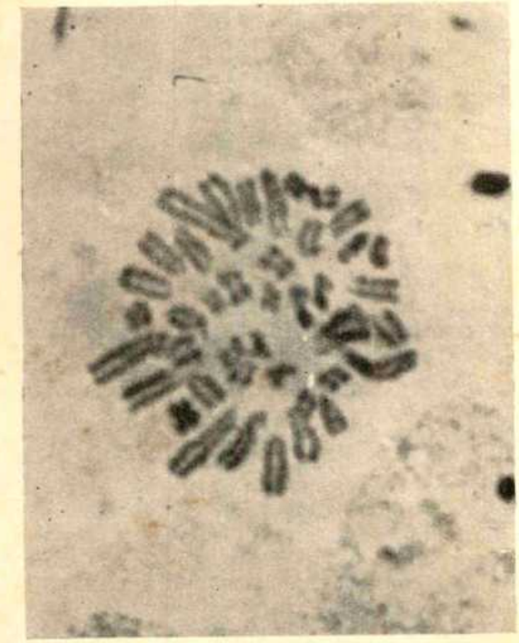

Fig. 1. Diploid metaphase ($2n = 42$; 12-days-old embryo) (×2,500)

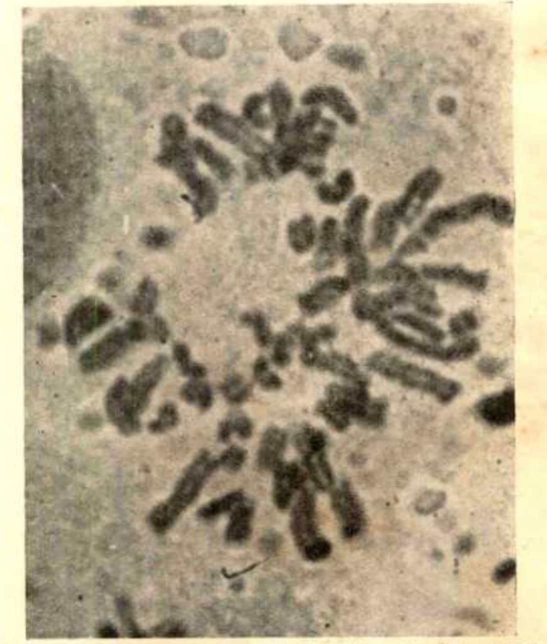

Fig. 2. Triploid metaphase (10-days-old embryo) (× 2,500)

without a spindle mitosis and includes the whole female chromatin. The higher doses of the drug frequently block the development of the pronuclei for up to 24 hr. Some evidence shows that androgenetic eggs may undergo cleavage, but their development stops at an early stage.

Twenty-four colchicine-treated females, and twenty-two females subjected to treatments to induce polyspermy (mostly of the Sherman strain), were killed 8–15 days after copulation. For the chromosomal examination whole embryos or, in later stages, the head were stained by acetic orcein after hypotonic pretreatment and squashed. Eighty-five embryos of the colchicine group and 219 embryos of the 'polyspermy' group were analysed; the results are given in Table 2.

Embryos classified as triploid contained predominantly triploid and near-triploid mitoses. Most of the mosaics contained triploid or near-triploid mitoses as well as other types of mitoses, the diploid number being, in general, the most frequent; these embryos might have come from originally triploid eggs. The remaining mosaics were diplo-aneuploid. There was practically no sign of 'somatic inconstancy' in the embryos classified as diploid. In an earlier study[8] by one of us, no deviation from the normal number was observed either in spermatogonia of adult rats.

Eight triploid embryos were highly retarded and clearly abortive; two triploids, however, both 10 days old and obtained in the 'polyspermy' group, were of normal size and appearance. Eight of the mosaic embryos were abortive while 14 appeared normal although more or less delayed in some cases.

To conclude, our results put forward new evidence that dispermic fertilization is a source of triploid embryos in the rat. It seems that most dispermic triploid embryos can become implanted and their further fate does not differ considerably from that of triploids of other origin.

Colchicine treatment after ovulation is an efficient method to induce heteroploidy in the rat; but few heteroploid embryos survive to mid-term. A large proportion of the heteroploid forms (including most triploids) die before or soon after implantation.

The disappearance of triploids, and the reduction in the number of mosaics, after 12 days gestation show that the chances of these heteroploid forms reaching term, whatever be their origin, are faint. This is in accordance with the failure (refs. 2–4 and Beatty, R. A., personal communication) to produce adult heteroploid (triploid) offspring. In fact, the 12 days old triploid embryos described here are, to our knowledge, the latest stage of triploidy recorded so far in any mammal.

Fractionation of Genes

After study of a dwarf tribe of Papuans at Aiome in the mountains of New Guinea in 1958 (not yet published), the conclusion was reached that they originated as a single-gene dwarf mutation from their tall neighbours who live at lower altitudes. This conclusion has since been confirmed by Champness *et al.*[1], who find that the blood groups of the tall and dwarf tribes in this area are essentially the same while the serology of a dwarf tribe in another part of New Guinea was markedly different. This supports the view that in mankind dwarf tribes or races have originated many times independently in different parts of the world, as they are known to have done in animals. In Africa it was concluded[2] that the Congo Pygmies arose long ago as a single-gene achondroplastic dwarf mutation from a tall race probably with mahogany skin colour.

In an extensive study of dwarf tribes in Dutch New Guinea, Bijlmer[3] found records of male stature stretching, perhaps in a step-like series, from 167 cm. (occasionally more) in the talls to 144·9 cm. as the lowest mean stature for a particular dwarf tribe.

Contemplating these and various other facts of dwarfing during a journey in India during October–December 1959, the tentative conclusion was reached that the intermediate heights of some Papuan tribes must have been derived in part from back-crossing of dwarfs to talls, accompanied by fractionation of the original 'large' gene for dwarfing and the production of 'smaller' genes having various intermediate effects. This is in accordance with the view I have always held that some mutations occur with large effects, as well as many with small effects. Having reached the conclusion that fractionation of genes must occur in some dwarf races, it was boldly decided to discuss this principle as soon as opportunity permitted a description of the Aiome dwarf race.

That opportunity has not yet occurred; but in the meantime, through the kindness of Dr. L. T. Ride, vice-chancellor of the University of Hong Kong, I was able in January 1960 to read back-numbers of *Nature*. In the number for December 19, 1959, I found a paper[4] which in one sense forestalled, but in another sense confirmed, the point of view mentioned above.

Briefly stated, the conception of the sub-gene is based[5] on experiments with the *T*4 bacteriophage and later with certain bacteria and lower fungi. From study of small differences in the phenotypic expression of a pair of genes in the *cis–trans* or coupling and repulsion phases it is shown that the cistron is a unit within the gene, and it may contain more than a hundred sensitive points at which a mutant phenotype may occur.

In the work of Fahmy and Fahmy[4], a large number of sex-linked recessive visibles obtained at the *r* locus by irradiation of *Drosophila melanogaster* proved to be a pseudo-allelic series, apparently involving several functional sub-units (cistrons) one or more at a time. That these are all intra-genic point mutations is shown by the absence of any band deficiencies in the *X*-chromosomes. Complementation maps indicate that six cistrons are involved in this series, which can be arranged in a linear sequence with overlapping.

Since the cistron conception is now established for an insect it may be assumed to apply to genes generally, including those of man. If genes contain, or consist of, cistrons then fractionation of the gene can occur, which will reduce the original genic effect. This principle is of wide importance in human genetics. In Eskimo X Nordic[6], the F_1 X Nordic can produce an individual having blue eyes, fair hair and white skin like the original grandfather. Thus the gene for blue eyes, for example, segregates as a complete unit in this racial cross. But in the European population many intergrades between blue and brown iris occur which have never been properly studied but which may be reasonably attributed to fractionation of the original gene.

As regards the blood groups, it is evident that ABO are original or ancestral genes, and that A_1, A_2, etc., are later developments produced by fractioning of the original gene so that its effect is milder in different degrees. Similarly, there is evidence that brachycephaly first appeared in the Upper Palæolithic as a marked departure from the previous dolichocephaly. Later, more extreme forms of brachycephaly as well as intermediate cephalic indices have probably been produced, partly by fractionation of the original gene, through hybridization, or otherwise. Thus in many cases the more extreme form of a gene appears first and its lesser and later forms bridge the gap by means of a series of sub-genes.

GEOLOGY

Geological Reconnaissance of the Sör-Rondane Mountains (Queen Maud Land)

In the course of the summer field parties of the Expedition Antarctique Belge 1957–58, I carried out a geological reconnaissance in the Sor-Rondane ranges, unexplored up to then.

This massif extends over approximately 250 km. east and west (from 23° E. to 28° E.) and has a depth of about 100 km. The foot-hills of the chain lie about 150 km. inland from the coast, at approximately 72° S. latitude. The summits are elevated between 1,200 and 3,500 m. above sea-level and the snow-line lies between 1,000 and 3,000 m.

The present topographical features have resulted from glacial erosion followed by a long stage of post-glacial erosion due mainly to mechanical weathering. The highest peaks investigated show evidence of heavy glaciation.

The region investigated is formed entirely of crystalline rocks, there being no trace of non-metamorphosed sedimentary rocks, nor of epizonal metamorphism.

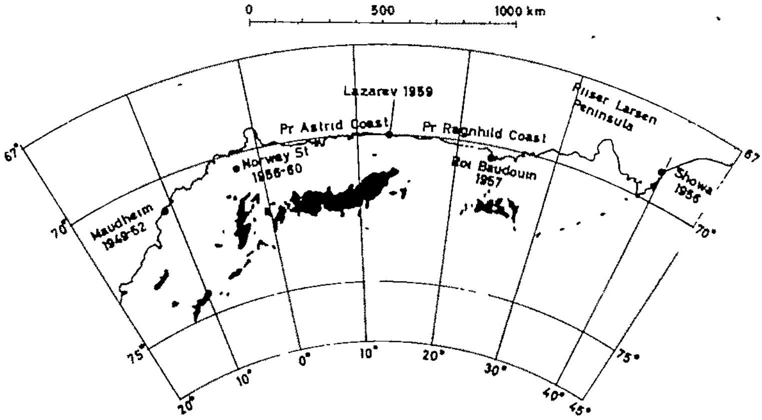

Fig 1. Queen Maud Land

The nunataks to the north of the chain are formed of intrusive igneous rocks (coarse-grained red granite at Roemnesfjell, diorites at Nordtoppen and Småhausane).

The mountain chain itself is formed of migmatites and highly varied, though mainly biotitic and amphibolic, gneiss. In one occurrence (at Austkampane) the gneiss is interspersed with layers of pure crystalline limestone associated with banks of calcium silicate gneiss. Homogeneous massifs of dioritic gneiss are also found. The general direction of the gneiss is east–west; the dip is very variable.

The gneissic complex, at certain points, is transected by a disordered network of pegmatitic and granitic dykes. The intensity and widespread occurrence of this phenomenon are striking characteristics of the region.

The phenomena of anatexy and of migmatization are widespread. This gneissic complex obviously forms part of the eastern Antarctic Pre-cambrian complex. The igneous intrusives to the north of the chain are clearly later than the gneiss but of unknown age.

There is no evidence of mineralization either in the gneiss or in the igneous intrusives.

The following successive stages in the geological history of this region are identifiable: (1) the deposition of a vast and varied sedimentary complex, including limestone deposits, under geosynclinal conditions; (2) the folding and metamorphism of the sedimentary complex in a deep zone (upper catazone), accompanied by dioritic intrusions; (3) the intrusion of granitic and dioritic rocks into the gneiss; (4) the formation of granitic and pegmatic dykes cutting through the intrusive bodies.

The radioactivity dating of the samples at present being carried out will furnish more precise information as to the chronology of these stages.

I wish to thank Dr. Jacques Giot, who led the sled journey into the Sör-Rondane, and Drs. Paul and Jean Michot, who are carrying out the petrographical study of the samples collected.

The geographical names refer to the map of the Sör-Rondane Mountains, published by the Norsk Polarinstitutt, in 1957.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

MAY AND BAKER RESEARCH FELLOW (honours graduate in chemistry)—The Registrar, Wye College (University of London), Wye, Kent (June 1).

ASSISTANT LECTURER, Grade "B", IN BIOLOGY; and an ASSISTANT LECTURER, Grade "B", IN CHEMISTRY—The Principal, Peel Park Technical College, Salford 5 (June 2).

ASSISTANT LECTURER IN GENETICS; and a LECTURER or ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, The University, Leicester (June 4).

LECTURER (graduate in pharmacology, physiology, biochemistry or veterinary medicine) IN THE DEPARTMENT OF VETERINARY PHARMACOLOGY—The Secretary, The University, Edinburgh (June 4).

ASSISTANTS (2) IN MATHEMATICS—The Secretary of University Court, The University, Glasgow (June 6).

UNIVERSITY DEMONSTRATOR (with an honours degree in chemistry or agricultural chemistry) IN SOIL SCIENCE—The Secretary, School of Agriculture, The University, Cambridge (June 8).

LECTURER or ASSISTANT LECTURER (qualified in pure or applied mathematics) IN MATHEMATICS—The Registrar, University College of North Staffordshire, Keele, Staffs (June 9).

DEMONSTRATOR IN THE DEPARTMENT OF PHYSICS—The Registrar, University College of North Staffordshire, Keele, Staffs (June 10).

LECTURER IN STATISTICS IN THE DEPARTMENT OF PURE MATHEMATICS; a LECTURER IN THE DEPARTMENT OF MATHEMATICAL PHYSICS; LECTURERS (2) IN THE DEPARTMENT OF PHYSICS; LECTURERS (2) IN THE DEPARTMENT OF CHEMISTRY; a LECTURER (preferably MYCOLOGIST) IN THE DEPARTMENT OF BOTANY; a LECTURER IN THE DEPARTMENT OF MECHANICAL ENGINEERING; a LECTURER IN THE DEPARTMENT OF ENGINEERING PRODUCTION; LECTURERS (3) IN THE DEPARTMENT OF CIVIL ENGINEERING; LECTURERS (2) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING; a LECTURER IN THE DEPARTMENT OF CHEMICAL ENGINEERING; a LECTURER IN THE DEPARTMENT OF PHYSICAL METALLURGY; and a LECTURER IN THE DEPARTMENT OF INDUSTRIAL METALLURGY—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (June 11).

TUTORIAL ASSISTANTS (2) IN THE DEPARTMENT OF GEOLOGY—The Registrar, University College of Wales, Aberystwyth (June 11).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree or five subjects at G.C.E. "O" level and at least two at "A" level) IN THE DEPARTMENT OF POTATO GENETICS, to assist in routine tests and pathological investigations—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (June 15).

LECTURER (with a degree in textile industries, followed by research experience; or chemistry, followed by specialization in textile chemistry) IN TEXTILE CHEMISTRY at the Home Science School, University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or The Registrar, University of Otago (New Zealand and London, June 15)

ASSISTANT LECTURER IN CHEMISTRY—The Registrar, The University, Leicester (June 18).

LECTURER or an ASSISTANT LECTURER (veterinary surgeon, or possessing a degree in an appropriate biological subject) IN VETERINARY PATHOLOGY—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (June 18).

LECTURER or SENIOR LECTURER IN APPLIED MATHEMATICS—The Registrar, The University, Sheffield (June 18).

SENIOR LECTURER IN SOLID STATE PHYSICS—The Registrar, The University, Sheffield (June 18).

LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, The University, Leeds 2 (June 24).

CHAIR OF MECHANICAL ENGINEERING AND HEAD OF THE DEPARTMENT—The Registrar, The University, Nottingham (June 30).

LECTURER (with a thorough knowledge of the physics of materials, and industrial or research experience involving semiconductors, polymers, magnetic materials, etc.) IN MATERIALS TECHNOLOGY IN THE DEPARTMENT OF ELECTRONIC ENGINEERING—The Registrar, University College of North Wales, Bangor, North Wales (June 30).

LECTURERS (2) IN PSYCHOLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

LECTURERS or ASSISTANT LECTURERS (with at least a good honours degree in mathematics and experience in teaching and research) IN MATHEMATICS at the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Malaya and London, June 30).

POSTDOCTORAL RESEARCH FELLOWS (with previous experience either in the chemical investigations of the structure of proteins or in the synthesis of peptides)—Dr. G. T. Young, The Dyson Perrins Laboratory, The University, South Parks Road, Oxford (June 30).

WAYNFLETE PROFESSOR OF PURE MATHEMATICS—The Registrar, University Registry, Oxford (June 30).

ASSISTANT DIRECTOR OF THE SOLAR PHYSICS OBSERVATORY, for research in solar or stellar physics, with some lecturing and light administration—The Director, Observatories, The University, Madingley Road, Cambridge (July 1).

SENIOR LECTURER and a LECTURER IN PHYSICS at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 1).

CHAIR OF PHARMACOLOGY in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, July 15).

PROFESSOR, and a READER IN THE DEPARTMENT OF MATHEMATICS, University of Rajshahi, East Pakistan—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (August 31).

ASSISTANT EXPERIMENTAL OFFICER (CHEMISTRY) (male or female, with a university pass degree in chemistry or agricultural chemistry)—The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, near Aberystwyth.

ASSISTANT, Grade "B" (with a good honours degree, and preferably industrial or research experience), FOR MATHEMATICS—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

ASSISTANT PROFESSOR (medically qualified or with a science degree of appropriate quality) IN THE DEPARTMENT OF MEDICAL BACTERIOLOGY—The Dean, Faculty of Medicine, The University of Alberta, Edmonton, Alberta, Canada.

CHEMISTRY MASTER, to teach throughout the school to "A" and "S" level G.C.E.—The Headmaster, The Perse School, Cambridge.

Computer to work in a small team concerned with plasma research—Prof. D. Gabor, F.R.S., Electrical Engineering Department, Imperial College of Science and Technology, London, S.W.7.

Experimentalist (with G.C.E. at "A" level, H.N.C. or equivalent and appropriate experience), to work in the Proton Physics Group of the Nuclear Physics Division engaged in the investigation of various methods, such as plating and vacuum evaporation, for producing thin targets for exposure in the Proton Linear Accelerator and also to work on nuclear detectors and to participate in the experimental work of the group which is using the P.L.A. for studying nuclear structure—The Senior Recruitment Officer (1672/34), U.K A.E A., A.E.R.E., Harwell, Didcot, Berks.

Junior Lecturer (Ph.D. standard in chemistry or biochemistry, and interested in pursuing research in microbiological chemistry) in the Department of Biochemistry—The Dean, London School of Hygiene and Tropical Medicine (University of London), Keppel Street, London, W.C 1.

Lecturer (graduate, with teaching and/or industrial experience in electronic and control technology, or a related branch of applied physics) in the School of Physics and Applied Science—The Registrar, College of Technology and Commerce, Leicester.

Lecturer (honours graduate, or with an equivalent qualification, preferably with industrial and/or teaching experience in statistics) in Statistics and Mathematics—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

Lecturers, Grade "B" (2) (graduates of a British university, one with qualifications and experience in electronics, and the other with qualifications and experience in theoretical and nuclear physics)—Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Professor (with a background of university teaching and significant research accomplishment, with relevant professional experience) of Mechanical Engineering (Chairman of the Department)—The Dean of Engineering, University of Waterloo, Waterloo, Ontario, Canada.

Research Assistant (with a degree in botany, and preferably an interest in mycology) in Botany—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1.

Research Assistant (with a degree in science or graduate member of the Royal Institute of Chemistry, or graduating this summer and qualified to work for a higher degree or research diploma) in Organic Chemistry—The Principal, Bolton Technical College, Bolton, Lancs.

Research Assistants (honours graduates in physics or students in the present graduation class), for work on problems concerned with counting techniques and high energy physics, gas discharges, spectroscopy or electronics—The Clerk to the Governors, Northern Polytechnic, Holloway Road, London, N.7.

Research Biochemist (Ph.D., preferably with a knowledge or research experience in the fields of pharmacology or pharmacological chemistry, clinical biochemistry or spectrophotometry), for investigations into the biochemical actions of drugs currently used in the treatment of mental illness, proceeding in conjunction with clinical studies on therapeutic action—The Director of Clinical Research, Crichton Royal, Dumfries.

Research Officer, Biochemist (with a good honours degree in chemistry or biochemistry, with postgraduate experience in biochemistry, preferably of animal nutrition and/or animal physiology) in the Animal Husbandry Division, East African Agriculture and Forestry Research Organization, Kenya—Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/151/C.1.

Senior Lecturer (with a good honours degree in mathematics) in Pure Mathematics—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18.

MANAGEMENT, EDUCATION AND BUSINESS STUDIES

In a circular issued to local education authorities on March 28, 1960*, the Minister of Education gave details of the radical changes which are to be made in schemes of management studies and commercial education in Britain. Due to take effect in the autumn of 1961, the changes will affect both the existing courses leading to the Intermediate Certificate and Diploma in Management, which are administered jointly by the Ministry of Education, the British Institute of Management and other professional management bodies, and the Ordinary National and Higher National Certificates in Commerce, which are administered by a joint committee of professional bodies, local education authorities and the Ministry of Education.

The changes in management education and commercial studies have been announced jointly because, to some extent, future arrangements will lead to amalgamation of existing courses and to much more simplified administrative arrangements for the control of the new courses which have been devised.

The development of education for management in England and Wales is described in the Report of a Working Party which is issued as an appendix to Circular 1/60. Following the report of the Committee on Education for Management appointed by the Minister of Education in 1945 under the chairmanship of Colonel L. F. Urwick, a scheme of management studies was begun in senior technical colleges about nine years ago. The courses recommended were of five years duration and led to examinations for the Common Intermediate Certificate in Management Studies at the end of three years and a Diploma in Management Studies which was taken at the end of five years. Over the nine years the Urwick courses have led to considerably increased interest in management education, and industry in Great Britain owes a considerable debt of gratitude to Urwick and his committee for devising practical schemes of management studies which at long last the country is beginning to take seriously.

Inevitably the pioneering courses have met with criticisms and these have been considered by the Working Party which began its work in October 1955. The need to reconcile conflicting views of numerous professional management bodies, industrial and commercial organizations, educational institutions and local education authorities has caused the Working Party to tread a tortuous path and to take an unconscionable time in producing its report. This was submitted to the Minister in October 1958, and the changes now announced represent another triumph in producing an agreed scheme which should do much to put management education at a level where it can no longer be ignored by the purists or by those practical men who came up the so-called hard way.

At present there is a lack of adequate provision for extended management courses of an advanced nature suitable for men and women who are already professionally qualified, and there are relatively few colleges with a nucleus of full-time staff able to develop such courses and to engage in research. So far, too, management education has been conditioned by its history in that it has usually been closely associated with economics and commerce, and has left in relative neglect the social sciences, particularly psychology and sociology. The Minister is convinced that there is both an educational and also a pressing economic need for a major advance, and proposes to set up a course leading to a Diploma in Management Studies. This course may not, in general, be taken by people unless they already possess graduate or equivalent professional qualifications and have had a measure of relevant practical experience in employment. If taken part-time, the courses will last three years, with a minimum entry age of twenty-three. No diplomas will be awarded before the age of twenty-six.

Entry to courses will normally be permitted only to students who hold a degree, a diploma in technology, a final professional qualification approved for the purpose, or a higher national diploma, or people in managerial positions whose education has been interrupted since leaving school and who do not have the necessary academic entry qualifications. For those with appropriate experience exceptional admission will be available.

Experience in management studies has shown the advantage of full-time, and especially full-time residential, courses over part-time courses. Those advantages are especially apparent for students of mature age and experience and of proved academic ability. The Minister indicates that full-time residential courses will increasingly be found to constitute the most satisfactory way of meeting the needs of the students for whom the Diploma scheme is designed.

In the existing courses many of the students are young, inexperienced youths who seek to obtain managerial positions by long and arduous studies spread over at least five years of often badly taught evening classes; others are frustrated clerks and some of middle age who have been passed over for promotion, and who turn to management evening classes to prove themselves and restore their fortunes. Much misery has resulted from this system, and the Minister now roundly calls upon employers to remedy this unsatisfactory position by supporting part-time or full-time day or, even more desirable, full-time residential courses.

In principle, postgraduate courses of the type envisaged should be conducted only in colleges which are well equipped and staffed for the purpose and which offer courses in other subjects at postgraduate level as well as advanced courses in the separate aspects and techniques of management. So far as full-time and sandwich courses are concerned, the Minister recommends that provision should be restricted to the Colleges of Advanced Technology and those Regional Colleges which are already conducting well-established courses at the level of the Diploma in Management Studies. Only by such concentration will it be possible to build up the nucleus of full-time staff well qualified in the economic, physical and social sciences and able to conduct the research and consultancy work which are the essential bases of a lively postgraduate course. This long-overdue step will do much to improve the quality of management education.

---

* Ministry of Education. Circular 1/60 (28th March, 1960): The Future Development of Management Education and of Business Studies—Revision of Joint Examination Schemes. Pp. 3. Appendix to Circular 1/60: Report of the Working Party appointed to examine the Scheme of Management Studies. Pp. 1+57. (London: Ministry of Education, 1960.)

Students of management would have been much happier with the Circular, however, if greater emphasis had been placed on the maintenance of adequate teaching standards at senior technical colleges by means of regular inspection. The Minister's statement would also have been improved if it had contained some reference to the well-known passage in the Urwick Report that "Theoretical Training alone does not make a Manager".

Besides the Diploma in Management Studies, Circular 1/60 also describes the setting up of two new National Certificates in Business Studies—an Ordinary and a Higher. These will replace the existing Common Intermediate Certificate in Management Studies as well as the Ordinary and Higher National Certificates in Commerce. Unlike the proposal to develop a new Diploma in Management Studies, which is likely to meet with the warmest support from thinking management in industry, the proposal to introduce Ordinary and Higher National Certificates in Business Studies may not meet with much enthusiasm. Ordinary and Higher National Certificates have acquired significance as qualifications pursued by enterprising youths and young men who attend part-time day and evening classes. The Ordinary and Higher National Certificates in Commerce have never acquired respectability, and to dissolve these into the new Ordinary and Higher National Certificates in Business Studies will give the latter emotional overtones which may take them a long time to throw off before becoming accepted as a genuine first step in management studies. An Ordinary National Certificate for genuine students of commerce should have been preserved. The Higher National Certificate in Commerce could well have been dropped, and a new certificate, similar to that proposed both by the Minister and the Working Party, should have been introduced. It should have no direct connexions with the Ordinary National Certificate in Commerce, the name "National" should not figure in it, and it should, as the Minister proposes, be available to all those students who at present take the Common Intermediate Certificate in Management Studies as well as students who hold Ordinary National Certificates in metallurgy, engineering, physics, commerce or any other discipline. The new Higher National Certificate in Business Studies will inevitably be regarded as the natural development from the Ordinary National Certificate in Business Studies. Its name may lead to its demise.

The third proposal contained in the Minister's circular is that an Advisory Council on Education for Management should be set up. Unlike the new diploma and certificates, which only apply to England and Wales, the proposed Council will be established by the Minister of Education, Secretary of State for Scotland and the Minister of Education for Northern Ireland, and will be concerned with management education in the United Kingdom. Such a Council is badly needed; it was one of the major recommendations in the Urwick Report. The three Ministers concerned are to be commended for its establishment, for its proposed composition, and its wide terms of reference. The Council will consist not only of representatives of appropriate educational institutions and of the major professional bodies concerned with management education but also representatives of those scientific and technological institutions which are themselves much interested in management education, together with representatives of both sides of industry and a number of other members with knowledge of management education generally, including management education in the universities. It will be concerned not only with the development of management education at levels beyond the equivalent of a university degree but also with the encouragement of research in management studies.

The new proposals should lead to a silent revolution in British industry. Despite all our success stories, those familiar with industrial undertakings are only too aware that the general picture is still one of muddle, mis-management and the rule of the thumb. Real work-study is little applied; budgeting is unknown; marketing is regarded as hocus-pocus: stock control using operational research techniques is regarded as unsuitable for 'practical' men. A significant difference between American and British industry is that the Americans have long believed in the value of management education; the consequences are well known. Top management in British industry should now grasp the opportunities provided by the Minister to spread the scientific mode of thought along the lines advocated by Urwick and other pioneers many years ago. Now that the Minister has come down so heavily on the side of residential courses for management studies, perhaps he may soon announce what the Government proposes to do to fulfil its election promise of setting up an Advanced Centre for Management Education with university status. He should also ask his newly appointed Advisory Council to examine the existing facilities for management education to see if some order may not be built up from the existing confusion. The diversified activities at the Administrative Staff College, management consultant training centres, university and technical college management courses should be brought together to fit into a unified pattern of education for management. Existing residential courses of the requisite standard should be accepted in part for the new Diploma in Management Studies.

RUSSIAN APPROACH TO MINERAL PARAGENESIS

Physiochemical Basis of the Analysis of the Paragenesis of Minerals

By D. S. Korzhinskii. Translated from the Russian. Pp. 142. (New York: Consultants Bureau, Inc.; London: Chapman and Hall, Ltd., 1959.) 7.50 dollars; 63s. net.

THIS book, which was originally published in Russian in 1957, is an excellent, clearly written, introductory discussion of the application of thermodynamics and the principles of projective geometry to the analysis of the paragenesis of minerals in multi-component heterogeneous natural silicate systems.

The first chapter discusses the thermodynamic principles governing mineral paragenesis and is especially notable in two respects. First, by its consideration of the extensive parameters, that is to say, those such as mass, volume, entropy and enthalpy, the magnitudes of which depend on the size of a system or phase as distinct from the intensive parameters such as temperature, pressure and concentration. These extensive parameters have long been neglected even in classical thermodynamics and this neglect has been carried over into most of the thermodynamic discussions of natural silicate systems. Secondly, and equally notable, is the extension of the phase rule to cover open systems and not just isolated and closed systems, which are now generally recognized to be extremely rare in geological conditions. Apart from his memorable studies of the basement rocks of eastern Siberia, the author is perhaps best known for his views on metasomatism and the significance of 'perfectly mobile' components the chemical potentials, activities and concentrations (not masses) in one of the phases or partial vapour pressures of which are factors of equilibrium of a system. Without such a concept of 'perfectly mobile' components the thermodynamic approach to open systems is impossible. The author is careful to restrict his consideration of components to independent components, but we must hope he will eventually extend his treatment.

The second chapter deals with methods of representing the chemical composition of various systems, especially multi-component ones, with emphasis on the use of projective geometry in graphical methods. Of particular interest is the use of vectors to represent many (for example, seven) component compounds, following Lodochnikov's earlier work. All the constructions are clearly explained and fully illustrated with admirably labelled diagrams.

Chapter 3 concerns the relation between the chemical and mineralogical composition of rocks under constant external conditions, and includes examples of the paragenetic analysis of minerals in multi-component systems, while Chapter 4 considers the dependence of mineralogical composition on external conditions. In this section more examples are given, which include the use of determinants in calculations of reactions in multi-component systems. A short explanation of the routine in using determinants is given.

In the brief final chapter a few general comments emphasize that in most naturally occurring mineral assemblages the problem is to find the conditions under which the minerals crystallized, using the observed or deduced paragenesis, and that the determination of the stable assemblage in each of numerous different, but associated, rocks is important, but frequently difficult to achieve. No mention is made of the vital importance of synthetic laboratory studies.

Examples of the application of the author's approach to particular systems such as the five-component system, CaO-MgO-SiO_2-CO_2-H_2O, and the paragenetic analysis of granitic rocks in relation to the chemical potentials of sodium and potassium, both of which are fully examined, are particularly interesting, and more examples would have been generally welcomed. It is unfortunate that some of the examples do not use co-existing minerals actually analysed and that in the last-mentioned example average chemical compositions of biotites and hornblendes in rather different rocks, and rather poor averages at that, should have been used as the basis for the calculations. Integration of some of the experimentally determined laboratory results available with the natural parageneses could have been profitably included.

Perhaps most important of all, this book directs our attention to the woefully inadequate training in physical chemistry and mathematics of, unfortunately, nearly all geologists. The prevailing emphasis in most universities on laboratory and field studies, to the almost complete exclusion of theoretical geology, especially thermodynamics, has resulted in most geological research becoming a distressingly empirical subject of unco-ordinated fact-finding, and we must welcome this new and fundamental, even if introductory, synthesis. BERNARD E. LEAKE

STEROLS AND TERPENES

Cholesterol

By Prof. David Kritchevsky. Pp. xi+291. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 78s. net.

Ciba Foundation Symposium on the Biosynthesis of Terpenes and Sterols

Edited by G. E. W. Wolstenholme and Maeve O'Connor. Pp. xii+311. (London: J. and A. Churchill, Ltd., 1959.) 45s. net.

ACCORDING to a note on the dust cover, Dr. Kritchevsky's book "provides a centralized source of information on the biological function and significance of cholesterol. It covers cholesterol chemistry, biochemistry, and physiology". One must undoubtedly admire the courage of an author who is willing to undertake such a herculean task, especially when a rival work, which appeared almost simultaneously, required 15 co-authors. As a guide to the literature, it is of considerable value, for reference is made to approximately 2,000 publications.

The first chapter, which deals with the chemistry of cholesterol and its derivatives, is only partially successful. In the space of about 50 pages, the reader is led from the first studies of gallstones in the first half of the eighteenth century to total syntheses of steroids at the beginning of the second half of the twentieth century. The result of such compression is likely to be difficult for biologists to understand and of little value to the chemist. For example, the Woodward synthesis is covered in eight lines of text and a flow-sheet. Sarrett's original synthesis of 11-ketoprogesterone is mentioned, but subsequent improvements (*J. Amer. Chem. Soc.*, 77, 1026, 3824 (1955)) have not been included. Johnson's synthesis of *epi*androsterone is omitted entirely (*J. Amer. Chem. Soc.*, 75, 2275 (1953)). This chapter closes with a useful account of methods of synthesis of isotopically labelled derivatives of cholesterol.

Knowledge of the biosynthesis of cholesterol has increased so rapidly that already the second chapter, through no fault of the author, is badly out of date. Realization that cholesterol biosynthesis proceeds through phosphomevalonic acid has come since the publication of this book. Details of the rearrangements which occur during the formation of lanosterol from squalene have also been elucidated recently.

During the remainder of the book, the author appears to be more at home with his subject, and there are successive detailed accounts of the absorption, transport, and metabolism of cholesterol, the implication of cholesterol in disease states, cholesterol-levels in the blood, and analytical methods for cholesterol. The overall impression which the reader is likely to gain from this part of the book is one of confusion. The author gives a detailed account of a mass of experimental results which abounds with apparent contradictions. Perhaps a more critical approach would have been better. Generous use of subheadings and tables, however, simplifies the reader's task to a considerable extent.

The book ends with a long and useful appendix, which contains a wealth of physical data on cholesterol, its derivatives, and related sterols. In addition, there are tables giving the cholesterol content of foods, sera, breast milk and tissues of many species. Typographical errors in structural formulæ were found on pp. 32 and 64.

The Ciba Foundation has a happy knack of organizing symposia in which the most eminent workers on biological subjects of great current interest are invited to contribute. The published records of these symposia are valuable both to those directly interested in the subject and to those who gamely continue the struggle to keep abreast of modern advances. The uninhibited discussions, which follow the individual contributions, enable the critical reader to appreciate divergencies of opinion among the experts, regions where hypotheses are ahead of experiment, and hence, the possible directions of future research. The present volume is no exception. The 17 papers, which comprise the symposium, cover most facets of the field of terpenoid and steroid biosynthesis. From acetate to cholesterol and the bile acids through such intermediates as mevalonic acid and its phosphate esters, squalene, and lanosterol, is a long story, but such has been the interest, particularly since the discovery of mevalonic acid, that most of the essential steps are now fairly clearly defined. The importance of acetate and mevalonate in the biosynthesis of triterpenes and carotenoids is clear, but these aspects of the field seem less fashionable than cholesterol, perhaps because of the clinical interest in the link between the biochemistry of cholesterol and atherosclerosis.

It is difficult to select any of the work reported in this volume for particular mention. One must, however, pay tribute to the painstaking work of Folkers' group; their discovery of mevalonic acid has provided a tremendous stimulus to biosynthetic studies in this field. For sheer brilliance of experimental technique, the elucidation, by Cornforth and his colleagues, of the mechanism of the rearrangement of methyl groups, which occurs during the cyclization of squalene to lanosterol, is difficult to surpass. The paper describing the biosynthesis of terpenoid compounds in fungi by Birch and Smith has an originality of ideas which stems from a combination of a wide knowledge of natural product chemistry and the mechanisms of organic chemical reactions. Thus, structures as different as mycophenolic acid, mycelianamide, gibberellic acid, and rosenonolactone are shown to be closely related biogenetically.

During the chairman's opening remarks and several times during the subsequent discussion, Sir Robert Robinson parades his anti-carbonium ion banner without seeming to intimidate all the authors, for a number of structures with integral positive charges on carbon are to be found within these pages. It should be remembered that this symposium deals necessarily with only a part of the story of the biosynthesis of terpenes and sterols, namely the nature of the reactions undergone by the substrates in the enzyme-controlled sequence which starts from acetate. Perhaps one day it will be possible to add the missing chapters and write out detailed reaction mechanisms, which include the parts played by the various enzymes, and then it may well be recognized that Sir Robert's criticisms are justified.

D. T. ELMORE

STATISTICAL METHODS IN BIOLOGICAL AND MEDICAL SCIENCES

Statistical Methods in Biology

By Dr. Norman T. J. Bailey. (Biological Science Texts.) Pp. ix+200. (London: English Universities Press, 1959.) 25*s*. net.

Elementary Statistics with Applications in Medicine and the Biological Sciences

By Prof. Frederick E. Croxton. Pp. vii+380. (New York: Dover Publications, 1959.) 16*s*. net.

THESE books are intended for different audiences. Dr. Bailey's book "is to provide workers in the biological and medical sciences with an elementary account of the chief statistical methods liable to be needed in practice". It does this admirably, in a very readable manner.

One of the features of the book is a separate summary of statistical formulæ, arranged so that the reader may easily find the technique appropriate to his problem. In the main text Dr. Bailey is careful to underline the pitfalls surrounding each method, but for obvious reasons of space these do not reappear in the summary. At the beginning of the summary Dr. Bailey warns: "If there is any doubt as to the application or interpretation of any formula, the reader should refer back to the full discussion". The reader should act on this frequently.

The main part of the book covers the usual field of such a treatise—basic ideas of estimation and significance tests, standard distributions and tests, and first principles of experimental designs. Mathematical symbolism is kept to a minimum. As a result, many formulæ appear without introduction: but this is justified by the book's intentions. Curiosity about mathematical derivations may be satisfied elsewhere.

The biologist will find this book extremely useful, both as a 'field guide' and for an insight into the methods employed in statistics. The statistician also would be advised to study this book, as an example of how lucidly statistical principles and arguments may be presented to non-mathematicians.

Dr. Bailey's book is not intended for undergraduate students as yet unfamiliar with research problems. It is to them that Prof. Croxton's book is directed. But as a whole, although the many excellent worked examples are medical in origin, the book is strongly biased towards methods more important to social scientists than to medical or biology students. The first third of the book is devoted to methods of presentation of data, and calculations of medians, modes, skewness and kurtosis. Thereafter the student is led through linear and non-linear correlation, (the word 'regression' appears only in the index), the normal, binomial and Poisson distributions, the reliability and significance of means and proportions, χ^2 tests, and finally a brief section on analysis of variance and allied procedures. As in Dr. Bailey's book, mathematical symbolism is avoided as much as possible; but replacing e by its numerical value in the normal distribution is surely carrying this 'simplification' too far. Prof. Croxton uses language and notation which is not standard, and some arguments, presented in general terms, are applicable only to the particular example under consideration. Although the book might be useful to a student of social medicine, it is on the whole unsatisfactory as an introduction to statistical methods as applied to experimentation.

Both books are attractively presented, Dr. Bailey's solidly bound, Prof. Croxton's in the well-constructed series of Dover reprints; and both are inexpensive by modern standards.

ADVANCES IN PLANT PHYSIOLOGY

Annual Review of Plant Physiology

Vol. 10. Edited by Leonard Machlis, in association with John G. Torrey. Pp. vii+483. (Palo Alto, Calif.: Annual Reviews, Inc., 1959.) 7 dollars.

The tenth annual review of plant physiology follows the same pattern as previous volumes in that no attempt is made to cover advances made in the whole range of plant physiology, but rather to concentrate on a number of restricted fields so as to give a picture of the present position of knowledge in them resulting from recent developments.

The subjects dealt with in the 19 articles which make up the present volume are diverse. Metabolism is well represented. Respiratory mechanism in higher plants, a subject which has attracted a great deal of attention in recent years, is dealt with by D. P. Hackett, and the closely related topic of the metabolism of carbon compounds by M. Gibbs. P. K. Stumpf and C. Bradbeer report on fat metabolism in higher plants, R. H. Burris on nitrogen nutrition and N. W. Pirie on leaf proteins. Two articles are concerned with chlorophyll-containing bodies, one by J. T. Wolken on the structure of the chloroplast, the other by A. W. Frenkel on reactions of bacterial chromatophores induced by light. Various aspects of mineral nutrition considered by W. H. Chandler, T. C. Broyer and P. R. Stout, and S. H. Wittwer and F. C. Teubner have a special bearing on horticulture and agriculture, while the article by G. G. Laties on active transport of salt into plant tissue deals with a fundamental problem of salt relations of plants.

As regards growth and development, J. Doorenbos and S. J. Wellensiek discuss the influence of photoperiod on floral induction, while two articles are concerned with growth-regulating substances, one on the chemical regulation of growth by a number of substances by F. C. Steward and E. M. Shantz, the other, by H. E. Gruen, on auxin and fungi. Phototropism and phototaxis are discussed by J. Reinert.

The remaining four articles are a miscellaneous assemblage, the subjects dealt with being lignins by R. E. Kremers, the pine tree by N. T. Mirov and R. G. Stanley, virus diseases by F. C. Bawden and plant chemotherapy by A. E. Dimond and J. G. Horsfall.

These articles are for the most part well written and generally avoid the fault of developing into a series of abstracts. They are highly informative and their production must have involved a vast amount of work on the part of the various authors. The high standard and usefulness of previous volumes is fully maintained in this latest annual review.

ROTATING FLUID MASSES

Figures of Equilibrium of Celestial Bodies, with Emphasis on Problems of Motion of Artificial Satellites

By Zdeněk Kopal. Pp. vi+135. (Madison: University of Wisconsin Press, 1960.) 3 dollars.

This important monograph is an exposition of the hydrostatic theory of self-gravitating fluid masses subjected to the distorting effects of rotation and tidal attraction. After a short introductory chapter, Prof. Kopal describes in Chapter 2 the first-order theory, due essentially to Clairaut, Legendre and Laplace, and discusses the mathematical properties of Clairaut's equation. The first-order theory assumes that the fluid mass departs from spherical symmetry by only a small amount, the square of which can be neglected. In Chapter 3 the theory is extended to cover the second-order effects of either the rotation of the body or the tides raised on it by a near neighbour; and in Chapter 4 the effects of interaction between rotation and tides are worked out. Second-order theory has previously been formulated by Callandreau, Darwin, de Sitter, Jeffreys and others; but Prof. Kopal's treatment is more general, and the contents of his Chapters 3 and 4 represent an impressive extension to the existing theory. The short Chapter 5, which concludes the book, discusses the free and forced oscillations of fluid bodies, with special reference to the possibilities of resonance.

The main application of the new theory is in double-star astronomy: in close binary systems the tidal effects in particular can be large enough to require a treatment correct to the second-order.

The subtitle of the book, "with Emphasis on Problems of Motion of Artificial Satellites", is most misleading, and would seem to have been added as an afterthought. These problems are not discussed, except in brief assertions on pages 4, 53 and 113 that the new theory will have an impact on Earth-satellite orbital studies. Since neither the solid Earth nor the atmosphere is exactly in hydrostatic equilibrium, and the Earth's surface is not an exact equipotential, it is difficult to see how the new theory can be directly relevant to the study of Earth-satellite orbits, and more explanation would certainly have been welcome.

It cannot be pretended that the book is easy to read, though this is due partly to the difficulty of the theory. When the author has the chance to relax from the rigours of mathematics, as in the introductory paragraphs of each chapter, his writing is lucid and lively: the last paragraph on page 87 is particularly admirable in giving new life to a well-worn metaphor. The book is printed by a photographic method from a typescript. The resulting product is extremely clear, but the appearance of some of the formulæ would have been improved by more frequent use of small type, especially in fractions. Trivial errors and misprints are commendably rare, though equation (1–39) of Chapter 2 seems to be wholly erroneous and should be replaced by equation (2–3) of Chapter 3.

D. G. King-Hele

FROM NUCLEUS TO UNIVERSE

From Nucleus to Universe
A Course of Selected Lectures in Physics and Astronomy, University of Sydney, January 11–22, 1960. Edited by Prof. S. T. Butler and Prof. H. Messel. Pp. 335. (Sydney: Shakespeare Head Press, Pty., Ltd., 1960.) 84*s*.

THE excellent lectures delivered at the first of the summer schools for science teachers at the University of Sydney, sponsored by the Nuclear Research Foundation, were reviewed in these columns some two years ago (*Nature*, 182, 623; 1958) and have recently been re-issued by Messrs. Macmillan. This present volume contains those given at the third summer school of January 1960. They are of the same high standard, and given by a most distinguished group of scientists. The chief difference from the earlier volume is the thread of continuity that makes it more like a symposium on a single central theme.

The first contribution, by Prof. S. T. Butler, on introductory atomic and nuclear physics, deals with nuclear structure in general, and the interaction between charged particles and radiation. Next, Prof. C. N. Watson-Munro, on advances in thermonuclear research, discusses the physical conditions for maintaining a thermonuclear reaction and the orders of magnitude to be expected. The problems of stability in both linear and toroidal pinch machines, the field convolutions of the Stellerator type, the magnetic-bottle devices and the means of ion injection, are described with helpful diagrams; and there is a short summary of the means available for studying what goes on inside a plasma.

Prof. G. Gamow's account of the universe and its origin is the longest individual contribution. He discusses both the evolutionary and steady-state cosmologies, together with the kind of evidence which would help to discriminate between them. On the evolutionary theory, for the first tenth of the lifetime of the universe, radiation must have preponderated over matter; and the first critical stage from which the protogalaxies emerged came when matter began to play a significant part in affairs. This lively field of controversy was, it appears, submitted to American astronomers by the Gallup pollsters; unanimity was expressed in the answer to one question only—that asking whether such a poll was of any use! Prof. Bart J. Bok continues Prof. Gamow's story with an account of the observational basis for stellar evolution.

R. Q. Twiss, on stellar interferometers, describes the Michelson interferometer as originally used for the measurement of stellar diameters, and then shows how, as an 'intensity' interferometer, it was adapted to measurements on radio stars. The next stage in the development, which involved so much discussion a few years ago on the correlation of photons in two coherent interfering beams, was to bring it back as an intensity interferometer into optics. This work has led to a new type of interferometer, of which an account is given.

T. Gold discusses the origin of the solar system, the structure and evolution of the Earth, and the probable state of the surface of the Moon. A. A. Day, on the interior of the Earth, takes two models of the mantle-core arrangement and describes the physical conditions associated with each, mentioning the information expected to be given by the project of boring a hole down to the Mohorovičić-discontinuity. "Space Physics" is the title of D. F. Martyn's contribution, which describes the problems of launching satellites, the processes of observing and tracking and obtaining information from them, and the results of satellite observations. H. D. Rathgeber describes the Van Allen belt of radiation, and its probable part in the origin of the auroræ. G. B. A. McCusker gives an account of cosmic radiation, mentioning the association with solar flares, and describing some of the very high-energy nuclear events observed in photographic emulsions exposed to cosmic rays. The study of conditions in the upper atmosphere by observations of meteor trails, micrometeorites and the zodiacal light are among the topics mentioned by G. Elford in his account of the science of meteors. Finally, K. B. Mather writes of research in Antarctica during the International Geophysical Year, and of work on the structure of the Antarctic continent.

The original aim of the summer school was to give teachers the means of arousing enthusiasm for science among their pupils, and to stimulate the flow of entrants to the university science courses; and the 1958 publication was effectively a permanent record for the participants. This is a more luxurious production, which is intended for a wider circle of teachers, and could be understood by their more enterprising pupils or by the interested layman. I do not feel justified in complaining about the price, which seems fair for a handsome limited edition of real intrinsic value; indeed, it would be conniving at the major education heresy of our times to imply that one can expect to get what is first-rate on the cheap. At the same time, it is a pity that this book is out of the reach of the thousands of teachers who would read it with delight, and of most of the librarians who are working to a budget. There must be some way of meeting the latent demand and the not-so-latent need for such a book; and perhaps on a future occasion it may be found. For this is more than a shot in the arm for the jaded teacher whose equipment is a little obsolete; it embodies the new outlook, or the resurgence, of a science that is still an adventure of the human spirit rather than the mere handmaid of technology. If we are to begin to think seriously, as we shall surely have to, about science as a liberal study in schools, this is the kind of book that will direct our thoughts along the right lines.

G. R. Noakes

SPACE SCIENCE

THE First International Space Science Symposium held during the second week of January at Nice was attended by nearly two hundred delegates from all over the world. The meeting was organized by the International Council of Scientific Unions Committee on Space Research and was held in the Centre Universitaire Méditerranéen. In the foyer and on the landing was arranged an exhibition of instruments for space research with a display of some experimental results. A particularly strong contribution from the United Kingdom brought the work of this country for the first time before the eyes of the world.

During the first decade after the War geophysical and astronomical research by means of rockets, or space research as it has now come to be called, made important but for the most part undramatic progress. With the approach of the International Geophysical Year the rate of firings increased greatly as rockets were launched by way of a dress rehearsal for that period of intensive effort. During the period itself this research with rockets ceased to be the prerogative of the United States and the U.S.S.R., as they were joined by Australia, Britain, Canada, and Japan and later by France. In the meantime artificial satellites were launched, and scientists of several nations who did not have facilities for their own launchings joined in the tracking of these bodies and made use of their orbital behaviour to determine more precisely the figure of the geoid and to study the density of the atmosphere above 200 km.

The meeting at Nice was the first opportunity for a comprehensive presentation of the work being done in various parts of the world, and it provided, both in its formal sessions and in informal periods, time for the discussion which was now due. Much of the work had been carried out during the International Geophysical Year, but important results obtained since, especially with lunar and deep space probes, were also presented. Indeed, the success of the International Geophysical Year firings, together, it must be admitted, with an element of international competition between the U.S.S.R. and the United States, has ensured that more use than ever is being made of rockets for research.

Table 1 compiled from the Committee of Space Research reports on national activities gives an indication of the various national efforts. Only successful firings are included, that is those in which the original objective was largely achieved.

The rockets used were generally either of the 1 ton–150 lb. payload class (for example, the British *Skylark*) or of the multi-stage small solid-propellant type (for example, the American *Nike-Cajun*). Altitudes were generally around 150 km. However, the Russians used their geophysical rockets. These can carry payloads of about 2 tons and reach altitudes of more than 450 km. Frequently much of this payload was used for experimental animals. In terms of payload carried, therefore, their effort compares favourably with that of the United States. Aspect control in the Russian work has been achieved by spherical containers, weighing about 700 lb. ejected from the geophysical rocket. *Lunik III* was of similar form. The Americans have made good use of aspect control for solar spectroscopy by employing *Aerobees* fitted with the University of Colorado *Sun-Seeker*.

Table 1. VERTICAL SOUNDING

	Rockets fired above 100 km. in 1959	Artificial satellites up to Dec. 31, 1959	Space probes up to Dec. 31, 1959
U.S A.	More than 36	4	1
U.S.S.R.	6	3	3
U.K.	7	—	—
Japan	4	—	—
France	3	—	—
Canada	1	—	—

Russian work has been characterized by a relatively high degree of standardization in the instrumentation (so that one type of instrument is flown again and again) and in the use of one rocket to carry many different experiments. On the other hand, the field of study of the Americans has been wider both as regards the phenomena investigated and the techniques used.

The hundred papers read at the conference were classified under seven headings. I shall endeavour to direct attention to some of the more important conclusions and results rather than to remark on individual papers.

In the opening session, on the Earth's atmosphere, Wexler discussed some of the doubts which have been current concerning the value of meteorological pictures made from satellites. He showed a film made during an *Atlas* firing which revealed a broad band of cloud associated with a front over the North Atlantic, the complex zone of the tropics and the organization of tropical clouds into streets, many of them aligned with the wind in the sub-cloud layer.

Important results obtained by the velocity of sound method in the Arctic, reported by Stroud *et al.*, showed the seasonal variation of wind and temperature. In the summer the prevailing winds were relatively gentle, usually less than 50 m./sec. from the east, while the temperature minimum at 80 km. was very deep, about 170° K. In the winter it was 60° warmer at this height and the winds were twice as fast and from the west. Two winter firings showed a breakdown of the circulation with strong northerly and southerly winds associated with sharp temperature increases in the stratosphere.

A comprehensive paper by Poloskov presented the Russian results on the neutral gas and the ionization. On the whole the data agreed well with the better-known American data. Mass spectrometer results showed the degree of dissociation of nitrogen up to 203 km. to be less than 2 per cent. Diffusive separation set in above 100 km., and the major positive ions found were atomic and molecular oxygen and nitric oxide.

In view of the importance of the ionosphere, and the amount of work done on it, the number of important results reported was remarkably small. Conspicuously lacking were data on sporadic and polar ionization, and on irregularities and motions. There was a tendency for the papers to deal with methods rather than results in this section. It is clear that Langmuir probes are emerging from the cloud of suspicion which has surrounded them since Langmuir's immediate successors found that their use was not always simple. Several of the papers were concerned with results from a study of satellite radio signals. Especially interesting are Garriott's results on the Faraday effect, which tend to confirm Evan's Moon echo measurements, that there are four times as many electrons above the *F* maximum as below. Thus above the maximum the concentration falls slowly. It was also found that magnetic activity could be accompanied by severe distortions of the profile, although the total content did not change.

The great importance of the discovery of the Van Allen belts of charged particles, trapped in the geomagnetic field, was reflected in the session on cosmic radiation and interplanetary gas. Eighteen papers were read, with important contributions from Van Allen, Vernov, Dolgmov and Kursanova and their collaborators. Van Allen gave the flux of electrons in the outer zone of energy greater than 40 keV. as 10^{11} (cm.^{2} sec.)$^{-1}$. At 200 keV. this had fallen by three orders of magnitude. The proton flux in the outer zone was less than 10^2 (cm.^{2} sec.)$^{-1}$ for particles more energetic than 60 MeV. The outer zone undergoes large fluctuations associated with solar activity, auroræ, atmospheric heating and magnetic storms. The inner belt is very constant in intensity and form and is thought to be due to decay of cosmic-ray neutrons. The electron fluxes are 100 times smaller than in the outer zone while the proton flux is about 100 times greater.

The Russian data agree fairly well with Van Allen's and extend the energy-range of the measurements. However, Vernov reported some apparent magnetic control of the inner zone intensity. In the same paper he gave the γ-ray flux in interplanetary space as less than 0·1 photon cm.$^{-2}$ sec.$^{-1}$ for energies greater than 450 keV., and less than 3 photons cm.$^{-2}$ sec.$^{-1}$ for energies greater than 45 keV.

Magnetic field measurements made by flux gate magnetometers were reported by Dolginov. These showed the existence of the field associated with the outer terrestrial radiation belt and also that the field of the Moon was less than 100γ. This gives a value for the lunar magnetic moment not more than ¼ per cent of the Earth's, in accordance with the idea that the Moon has no liquid core. The same general conclusion is indicated by the lack of evidence for a lunar -radiation belt in the data obtained by *Lunik II*.

Cosmic ray measurements by *Lunik II* gave the following ratios for the fluxes of heavy rays, 1,000 : 75 : 3 for *Z* values 2 : 5 : 15. An interesting possibility suggested by some of these results, but not yet confirmed, is the trapping of α-particles in a radiation-belt situated 20,000 km. from the Earth's centre.

In the sessions on tracking and telemetry the paper by O'Keefe was of geophysical importance. Early studies of artificial satellite orbits gave a value of 1/298·3 for the equatorial bulge, which is about 1½ per cent less than the internationally accepted value. These studies considered only the second harmonic, but in 1958 it was pointed out in Great Britain that the use of orbits at various inclinations would make it possible to determine higher harmonics simply from the precession-rates. On the other hand, it was found that a careful elimination of the effects of drag from the high satellite *Vanguard I* resulted in a motion containing two secular terms and four terms of period equal to the period of revolution of the line of apsides. Two of the periodic terms are interdependent, but the remaining five coefficients lead to values for the 2nd, 3rd, 4th and 5th harmonics. These results show that the shape of the geoid is not that which it would have if it were in rotational equilibrium. Indeed, it is not even symmetrical, as there is a significant 3rd (but not 5th) harmonic. O'Keefe considers the possibility that the distortion is due to convection currents, and rejects it on energetic grounds in favour of Jeffrey's model. He concludes that the Earth has considerable mechanical strength. It does not seem possible that the Earth's interior is a viscous fluid with a viscosity around 10^{22} poises as has been supposed.

The study of solar radiation is one of the most important branches of space science. As a sample star, close at hand, the Sun is of immense astrophysical significance, while its short-wave radiation is responsible for the ionosphere, with its varied structure and behaviour. The extensive and systematic work of the team at the Naval Research Laboratory, Washington, was among the most beautiful (if the term may be allowed) reported at the symposium. This team has used ionization chambers, high-resolution grating spectrographs and double-grating imaging monochromators to obtain valuable data on the emission spectrum, and to photograph the solar-disk in Lyman-α radiation. Good use has been made of the University of Colorado *Sun-seeker* to obtain details of the Lyman-α profile and to reveal strong reversal in the centre of the line.

Taking the American work as a whole (no work on solar ultra-violet or X-rays was reported from the U.S.S.R.) the outstanding results to date are summarized in the following quotation from a paper by Rense: "(1) Extension of the solar Fraunhofer spectrum to about 1500 Å. and the identification of over 1,000 absorption lines. (2) The detection of the prominent hydrogen Lyman-α line and the measurement of its absolute intensity. (3) The determination of the half-width and profile of the hydrogen Lyman-α line. (4) The detection of several members of the Lyman series and the continuum. (5) The detection of the ionized helium resonance line at 303·8 Å. and the establishment of its relatively high intensity. (6) The detection and wave-length measurements of several hundred emission lines extending from about 1900 Å. to 84 Å., with positive identification in many cases. (7) The measurement of the approximate absolute intensities of several of the less-intense emission lines. (8) Successful photography of the Sun's disk in hydrogen Lyman-α radiation".

The work on X-rays has concentrated chiefly on the effects of the flares. For flares in the range class 2–3 the flux between 20 and 100 Å. has averaged about 2 ergs cm.$^{-2}$. Between 8 and 20 Å. it was found to be about 3×10^{-2} erg. cm.$^{-2}$ and between 2 and 8 Å., about one-third of this value. Considerable hardening of the radiation thus occurs during such flares, together with a doubling of the total flux. Results suggest the existence of local thermal sources with a temperature of the order of 10^6 ° C.

The session on the Moon and the planets contained a number of papers, reflecting the stimulation of interest in these fields by the rapid development of space technology. Of special note is the serious consideration now being given to space biology. The only rocket results reported in this session, however, concerned the now well-known *Lunik III* photograph of the reverse side of the Moon. It is a pity that the unique techniques employed in this superb piece of work were not discussed in greater detail.

R. L. F. Boyd

PRIMARY PROCESSES IN THE ACTION OF IONIZING RADIATIONS ON WATER: FORMATION AND REACTIVITY OF SELF-TRAPPED ELECTRONS ('POLARONS')

By Prof. JOSEPH WEISS

Department of Chemistry, King's College, University of Durham, Newcastle upon Tyne

DURING recent years, the study of the chemical action of ionizing radiation has been largely based on the hypothesis that the chemically active species are atoms and free radicals produced by radiation. This was introduced into the radiation chemistry of water, when it was suggested[1] that the absorption of the radiation leads to H atoms and OH radicals ($H_2O \rightsquigarrow H + OH$). These general ideas were later also extended to other systems. From a physical point of view, the absorption of ionizing radiations is known to lead to ionization and excitation. It seemed likely, therefore, that some primary species in the nature of ions and excited molecules could play some part in these processes. At first, it was generally assumed that any such species formed would be very short-lived precursors and of no importance for the chemical reactions. In 1953, it was suggested[2] that such a view cannot be wholly correct, because while it was reasonable to suppose that excited molecules would undergo pre-dissociation into free radicals in times of the order of 10^{-13} sec., it seemed probable that, in general, the ionic precursors may play quite an important part in the mechanism of chemical reactions induced by radiation. In 1957, some definite evidence could be produced[3] to show that positive as well as negative ionic species formed from the water may be important in the radiation chemistry of aqueous systems. In fact, it could be demonstrated that there were two reducing species present in solution, namely, hydrogen atoms and electrons. The ('self-trapped') electrons in the dielectric medium (water) were tentatively identified with the 'polaron', which was known from the work of Landau[4], Mott[5] and Pekar[6] on the behaviour of electrons in ionic crystals.

Recent work has fully confirmed these views[7,8] and has also shown that these 'polarons' are normally relatively stable. On the basis of the known physics of the 'polaron', this is exactly what was to be expected: the polaron is an electron produced by radiation and thrown into the water, where it polarizes the surrounding medium and in turn, by its own field, keeps the polarization of the medium in a stationary state. From the theory of Pekar, one can calculate the mean radius (r_p) of the polaron, which is given by the equation[6]:

$$r_p \simeq \frac{10\hbar^2}{c\mu e^2} \qquad (1)$$

where the parameter c is $(1/n^2 - 1/\varepsilon)$, in which n^2 is the optical dielectric constant; ε is the static dielectric constant; μ is the effective mass of the electron; $\hbar$ is Planck's constant; e is the electronic charge. In the case of water ($c \simeq 0{\cdot}55$), this would lead to a value of the order of $r \sim 10$ Å., assuming that μ is equal to the rest mass (m) of the electron. In water, the conditions for the existence of a polaron are, in fact, fulfilled[6], as the electronic frequency of the polaron is always very much greater than the proper frequency of the ionic vibrations and considerably less than the frequency of the bound electrons in the dielectric medium.

The polaron is thus not to be pictured as an electron attached to a particular water molecule, but as an electron belonging collectively to a comparatively large number of water molecules with a radius corresponding to the de Broglie wave-length of the electron. This makes it conceivable that the polaron should be relatively stable with regard to dissociation, according to:

$$(H_2O)^- \rightarrow H + OH^- \qquad (2)$$

which is due to the fact that the average time which the electron spends on a particular water molecule is small compared with the time (10^{-11} sec.) necessary for the dissociation and solvation of the resulting OH^- ion.

On the other hand, it is equally obvious that the polaron should be capable of interacting with a suitable centre in the water, by which it can be trapped or annihilated. In the absence of any other 'traps', the positive centres resulting from the removal of an electron from a molecule of the solvent, which may be regarded as positive polarons, would react according to:

$$(H_2O)^- + (H_2O)^+ \rightarrow 2H_2O \qquad (3)$$

Such a reaction may, in fact, be the main cause for the relatively low yields of free radicals produced by irradiation of liquid water as compared with the yields in water vapour[9]. If, on the other hand, there are, for example, a sufficient number of hydrogen ions in solution, competition will be set up by the reaction of the polaron with the hydrogen ions, according to:

$$(H_2O)^- + H^+ \rightarrow H + H_2O \qquad (4)$$

leading to the formation of hydrogen atoms. There is, however, also some direct formation of hydrogen atoms, in a relatively low yield, from the dissociation of excited water molecules according to:

$$H_2O^* \rightarrow H + OH$$

The above considerations do not affect the secondary formation of H_2^+ ions[3] from H atoms and hydrogen ions ($H + H^+ \rightleftarrows H_2^+$) in relatively acid solutions.

In the presence of a suitable solute which can act as a polaron acceptor, this will also be competing for the polaron. For example, in the case of monochloroacetic acid, this reaction can be represented by[3]:

$$(H_2O)^- + Cl.CH_2.COOH \rightarrow Cl^- + CH_2COOH + H_2O \quad (5)$$

Other reactions are, for example, the reaction with hydrogen peroxide, according to:

$$(H_2O)^- + H_2O_2 \rightarrow OH^- + OH + H_2O \quad (6)$$

or

$$(H_2O)^- + O_2 \rightarrow O_2^- + H_2O \quad (7)$$

In solutions containing more than one acceptor one will, of course, have competition, as, for example, between reactions (3) and (7), respectively.

Another point of interest concerns the interaction of two polarons. It is well known that in the radiolysis of water a certain amount of molecular hydrogen is produced directly, presumably in the tracks of the ionizing particles. It has been thought previously that this may be due to the interaction of hydrogen atoms. However, such an assumption is not in agreement with many of the experimental facts. More recently[3], it has been suggested that this is due to the interaction of two of the ionic precursor species, which may lead to the formation of molecular hydrogen on one hand, and molecular hydrogen peroxide on the other hand, according to:

$$2(H_2O)^- \rightarrow H_2 + 2OH^- \quad (8)$$

$$2(H_2O)^+ \rightarrow H_2O_2 + 2H^+ \quad (9)$$

In view of the relatively great stability of the polarons, it is now perfectly conceivable that such bimolecular interactions may take place, particularly in regions of relatively high-ionization density.

It is interesting to look again at the physical situation: it is well known that the so-called *F′* centres can exist in an ionic crystal; these are believed to be two electrons occupying a negative vacancy. Such a configuration is stable and its stability is essentially due, in spite of the repulsion of the electrons, to the interaction of the electrons with the positive charges surrounding them. In fact, the net charge of the *F′* centre is the same as that of a mononegative particle. The situation is, however, different if there are no free positive charges present. In the case of a single polaron, the theory predicts considerable stability in a medium of high dielectric constant. However, for the same reasons one can show that what could be a 'bi-polaron' must be a highly unstable entity[8]; that is, if two polarons meet, they either repel each other or, if there is a possibility of a chemical interaction, mutual annihilation will occur.

Irradiated Ice

Some other indications for the existence of polarons can be derived from electron spin resonance measurements on irradiated ice and frozen acids (for example, sulphuric or perchloric acid). When acids are present in the ice, atomic hydrogen has been definitely established from observations of the hyperfine structure, and this was also confirmed by work on the D_2O-system[10]. On the basis of the above considerations, the formation of hydrogen atoms would be due to a capture of the polaron by the hydrogen ions of the acid according to equation (4). Such a view is to some extent supported by the fact that, in pure ice, no evidence for hydrogen atoms could be obtained[11]. A doublet and some other unresolved lines were observed after irradiation of pure ice, the former corresponding to a $g = 2 \cdot 0085$. Such a spectrum would not be incompatible with the presence of polarons, but cannot, of course, be regarded as a proof for these species.

When pure ice is irradiated, for example, with X-rays, a steady-state fluorescence and a weak, but reproducible, thermoluminescence is observed[12]. The fluorescence induced by irradiation of ice is suppressed in the presence of 2×10^{-5} *M* hydrogen peroxide, but on further irradiation the original luminosity is restored; this was found to be due to the gradual decomposition of the hydrogen peroxide during the irradiation. Presence of hydrogen peroxide likewise suppresses the thermoluminescence.

These phenomena, again, can be interpreted on the basis of the conversion of radiation energy into ionization and excitation.

Excitation in the solid may result in the formation of an 'exciton', and it is quite possible that the emission of fluorescence is, in fact, due to the radiative deactivation of 'excitons' in the ice.

On the other hand, ionization would lead to the formation of polarons: the observed decay of thermoluminescence, which is a first-order process and corresponds to a trap depth of about 0·3 eV., would be compatible with such an assumption. The trap depth of 0·3 eV. is, in fact, rather close to the value for the binding energy of the polaron in the ground state (H_0), which can be derived from Pekar's theory, who gives the expression[6]:

$$H_0 = -1 \cdot 47 \frac{\mu}{m} c^2 \text{ (eV.)} \quad (10)$$

Thermoluminescence could thus be due to the radiative annihilation of a positive and negative polaron according to reaction (3), or the radiative interaction of the polaron with an impurity centre. For water ($c^2 \simeq 0 \cdot 3$) and $\mu \sim m$, this gives a value of $H_0 = -0 \cdot 44$ eV.

I wish to thank Prof. N. F. Mott for his very helpful comments.

EQUIVALENCE OF LIGHT AND ADENOSINE TRIPHOSPHATE IN BACTERIAL PHOTOSYNTHESIS

By DR. M. LOSADA, Dr. A. V. TREBST, S. OGATA and PROF. DANIEL I. ARNON
Laboratory of Plant Physiology, University of California, Berkeley

PHOTOSYNTHETIC phosphorylation[1,2] has provided direct experimental evidence for the view that the key event in photosynthesis, the conversion of light into chemical energy, is independent of the classical manifestations of this process in green plants—oxygen evolution and carbon dioxide reduction. In the light-dependent phosphorylation of the cyclic type, that is the common denominator of photosynthesis in plants and bacteria, carbon dioxide is not assimilated nor is oxygen evolved; the only identifiable chemical product of the absorbed light energy is adenosine triphosphate[3,4].

In photosynthesis of green plants the contribution of light is not limited to the synthesis of adenosine triphosphate, but also includes the formation of reduced triphosphopyridine nucleotide[3]. Adenosine triphosphate and reduced triphosphopyridine nucleotides, jointly called assimilatory power[5], are then used for carbon dioxide assimilation. All the reactions of carbon dioxide assimilation occur in the dark and are also present in non-chlorophyllous cells[6-9] and must therefore be considered as being removed from the energy conversion process peculiar to photosynthesis. The validity of this concept of photosynthesis has been documented in isolated chloroplasts by separating experimentally their light and dark reactions, and by characterizing their carbon dioxide assimilation[10-13].

We have recently reported that, in the presence of hydrogen gas, the contribution of light in bacterial photosynthesis may be limited to the formation of adenosine triphosphate[3]. Similar views have also been expressed on the basis of independent evidence by Stanier, Doudoroff, Kunisawa and Contopoulou[14]. The reductant required for carbon dioxide assimilation, reduced pyridine nucleotide, is, unlike in green plants, formed in the *dark* by the external hydrogen donor, molecular hydrogen[3,4]. It follows, therefore, that if light is replaced by exogenous adenosine triphosphate, photosynthetic carbon assimilation should proceed entirely in the dark.

The substitution of adenosine triphosphate for light would be particularly significant if it could be demonstrated in such photosynthetic bacteria as *Chromatium*, that are unique in the living world in being strict phototrophs. *Chromatium*, unlike, for example, *Chlorella*, or photosynthetic bacteria of the genus *Rhodospirillum*, cannot replace its light-dependent mode of life by a heterotrophic, aerobic metabolism in the dark[15-17]. *Chromatium* grows only in the light[15,16], and being an obligate anaerobe, cannot carry out oxidative phosphorylation.

The purpose of this article is to report evidence which we have now obtained for the equivalence of light and adenosine triphosphate in the photoassimilation by *Chromatium* of carbon, supplied either as carbon dioxide or acetate. The findings to be reported support the view that bacterial photosynthesis is the prototype of photosynthesis in green plants, where it became modified in the course of biochemical evolution, to include oxygen evolution and the formation by light of a reductant for carbon dioxide assimilation[3].

Carbon Assimilation by Whole Cells

Until recently, the prevailing view of carbon assimilation in photosynthetic bacteria was that these organisms resemble green plants in forming most of their carbon compounds by reducing carbon dioxide. It was known for a long time that *Chromatium* can assimilate organic substrates in light[16]; but, in the main, these came to be regarded as hydrogen donors, rather than as sources of organic carbon for further photosynthetic elaboration into cellular material[17]. Stanier *et al.*[14] have now reopened this subject by showing that in "resting" cells of *Rhodospirillum rubrum* "acetate is converted anaerobically in the light largely to poly-beta-hydroxybutyrate". We have therefore re-examined the assimilation of carbon under different conditions using 'growing' *Chromatium* cells.

As shown in Table 1, significant fixation of carbon dioxide, labelled with carbon-14, by *Chromatium* cells occurred, as expected, only in the light and was greatly increased by the addition of malate, succinate, thiosulphate, sulphide, and molecular hydrogen. Acetate was an exception; it did not increase fixation of carbon dioxide.

The assimilation of acetate acquired special interest when we found, in parallel experiments, that *Chromatium* was able to grow with acetate as the sole source of carbon without added carbon dioxide. *Chromatium* has been grown with acetate previously[16] but always in the presence of added carbon dioxide. Since acetate did not aid the assimilation of labelled carbon dioxide (Table 1) and supported growth without the addition of carbon dioxide, it might have served as

Table 1. EFFECT OF LIGHT AND OF INORGANIC AND ORGANIC 'REDUCTANTS' ON CARBON-14 DIOXIDE ASSIMILATION BY *Chromatium* CELLS

Treatment	Total $^{14}CO_2$ fixed (counts × 1,000/min.)
1. No 'reductant' added*, dark	80
2. No 'reductant' added, light	270
3. Acetate, light	270
4. Malate, light	630
5. Succinate, light	1,000
6. Hydrogen, light	1,320
7. Thiosulphate, light	1,020
8. Sulphide, light	1,040

* In the dark, no increase in carbon dioxide fixation was observed on adding any one of the 'reductants' listed in treatments 3–8.

Each vessel contained a modified culture solution (ref. 26) and cells equivalent to 0·2 mgm. bacteriochlorophyll; also the following in µmoles: *Tris*, *p*H 7·8, 60; carbon-14 bicarbonate, 10; 'reductant', 10 (except in treatment 6). Final volume 2·5 ml. Gas phase was argon, except in treatment 6, which received hydrogen gas. The reaction was carried out at 25° C. and stopped after 30 min. by adding 0·1 ml. 5 *N* hydrochloric acid.

Table 2. EFFECT OF LIGHT AND CYANIDE INHIBITION ON CARBON ASSIMILATION BY *Chromatium* CELLS

Treatment	Total carbon-14 fixed (counts × 1,000/min.)
1. Carbon-14 acetate, dark	8
2. Carbon-14 acetate, light	480
3. Carbon-14 acetate, light	520
4. Carbon-14 acetate, 10^{-3} *M* cyanide, light	520
5. Carbon-14 dioxide, hydrogen, light	3,200
6. Carbon-14 dioxide, hydrogen, 10^{-3} *M* cyanide, light	1,500

Prior to the experiments the cells in treatments 1–4 were grown with acetate as the 'reductant' and the cells in treatments 5 and 6 with hydrogen gas (ref. 26). Treatments 1 and 2 were run for 20 min. and included, in each reaction vessel, cells equivalent to 0·13 mgm. bacteriochlorophyll; final volume 1·9 ml. Treatments 3–6 were run for 30 min. and included cells, equivalent to 0·2 mgm. bacteriochlorophyll, and 3 μmoles carboxyl-labelled acetate; final volume 2·5 ml. Gas phase was argon, except in treatments 5 and 6. Other conditions as in Table 1.

a direct source of carbon, but one that in *Chromatium* cells could be assimilated only in light.

We tested this interpretation by supplying radioactive acetate in the light and in the dark to 'growing' *Chromatium* cells in short-term experiments. The results are shown in Table 2. No significant assimilation of labelled acetate occurred in the dark. In the light a marked incorporation of acetate took place and was not affected by the addition of carbon dioxide.

Table 2 also presents evidence that the photoassimilation of acetate occurred by a pathway independent of that of carbon dioxide assimilation. We have previously reported that, in chloroplasts, the reductive carbohydrate cycle for carbon dioxide assimilation is inhibited by cyanide[13]. Table 2 shows that, in *Chromatium* cells, cyanide inhibited the assimilation of carbon dioxide, but not that of acetate. It seems, therefore, that carboxydismutase, which is the enzyme of the reductive carbohydrate cycle that is specifically inhibited by cyanide in *Chromatium* and in chloroplasts[13], is not involved in the photoassimilation of acetate by *Chromatium*. Acetate was apparently used by *Chromatium* cells not as a reductant in carbon dioxide assimilation but as a carbon compound that was readily photo-assimilated into cellular substance without external carbon dioxide and without being first oxidized to carbon dioxide.

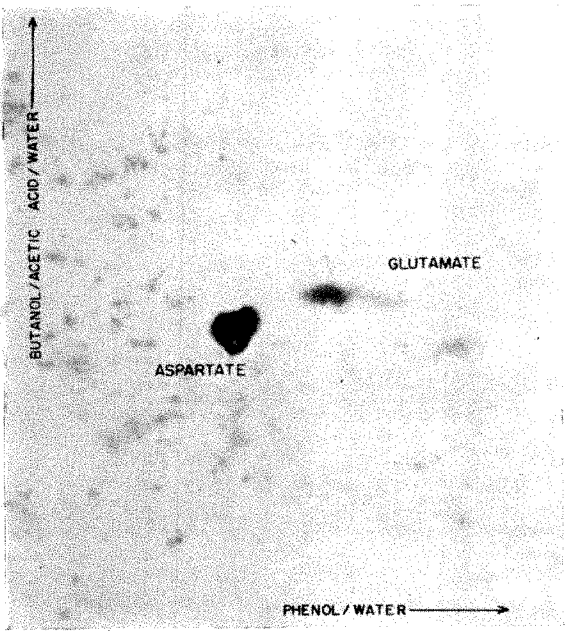

Fig. 1. Radioautograph of a chromatogram showing soluble products of carbon-14 dioxide assimilation in the light by *Chromatium* cells. Experimental conditions as in treatment 5 of Table 2, except that thiosulphate was used instead of hydrogen

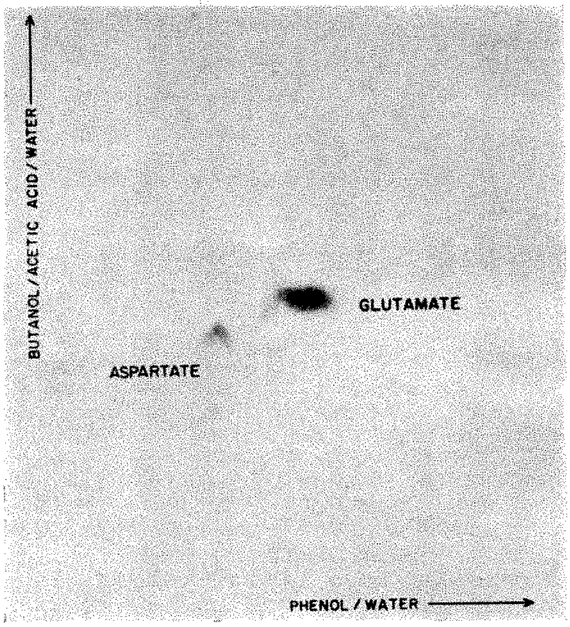

Fig. 2. Radioautograph of a chromatogram showing soluble products of carbon-14 acetate assimilation in the light by *Chromatium* cells. Experimental conditions as in treatment 3 of Table 2

The conclusion that carbon dioxide and acetate represent two independent pathways for carbon assimilation in *Chromatium* cells was strengthened by a comparison of the products formed. The identification was made by the techniques of paper chromatography and radioautography[11]. When labelled carbon dioxide was the sole source of carbon, and the reductant was either molecular hydrogen, thiosulphate, sulphide, malate or succinate, the main soluble products formed (approximately 50 per cent of the total carbon fixed) were in all cases amino-acids, principally aspartic acid.

A typical chromatogram is shown in Fig. 1. In general, phosphorylated sugars were much less prominent in *Chromatium* than in isolated chloroplasts[11–13] and in certain experiments no sugars were detectable by the identification techniques which we used. The prominence of aspartic acid among the products of carbon dioxide fixation is in agreement with the report of Fuller[18] that "in *Chromatium* the primary pool of fixed carbon is aspartic acid".

With radioactive acetate the products of photoassimilation in the soluble fraction (about 10 per cent of the total carbon fixed) were again mainly amino-acids, but here glutamate was the principal product formed (Fig. 2).

To recapitulate, then, carbon dioxide and acetate assimilation seemed to proceed in *Chromatium* by two separate pathways that had a common link in being strictly dependent on light. It now remains to be shown that, in both pathways, light is replaceable by exogenous adenosine triphosphate.

Carbon Dioxide Assimilation by Cell-free Preparations

The equivalence of light and adenosine triphosphate might have been directly demonstrated in whole cells if it were possible to accumulate or introduce substrate quantities of adenosine triphosphate for driving carbon dioxide fixation in the dark. However, a preliminary accumulation of adenosine triphosphate in the light is not possible because whole cells have only catalytic amounts of adenosine diphosphate. The introduction of exogenous adenosine triphosphate is also excluded by the impermeability of whole cells to adenylates. Experimentally, therefore, the problem is how to overcome the permeability barrier of the cells to adenylates without damaging excessively the photosynthetic apparatus.

In the case of green plants the permeability barrier of whole cells was set aside by using broken chloroplasts[10]. In the case of *Chromatium* the cells were ground with alumina and the cell-free fluids were separated by differential centrifugation into chromatophores that contained the photochemical apparatus proper, capable of photosynthetic phosphorylation outside the cell[19-21], and into a supernatant fluid which contains the carbon dioxide fixing enzymes[22]. The role of light and adenosine triphosphate in carbon assimilation by the cell-free preparations was investigated in parallel experiments using either carbon dioxide or acetate as the source of carbon.

Carbon dioxide assimilation in cell-free preparations of *Chromatium* seemed to proceed, as was the case in broken chloroplasts[12], by the reductive carbohydrate cycle. However, in the case of *Chromatium*, phosphoglycerate was the product that was being removed from the cycle and converted into phosphoenolpyruvate, which is the substrate of a second carboxylation reaction resulting in the formation of oxalacetate and aspartate. The enzyme that catalyses this carboxylation, phosphoenolpyruvate carboxylase, is also present in chloroplasts[23], but there, on present evidence, it does not seem to play as direct a part in photosynthetic carbon dioxide assimilation.

In the presence of exogenous ribulose diphosphate or phosphoenolpyruvate, cell-free preparations of *Chromatium*, like whole cells, assimilated carbon dioxide mainly into aspartic acid without any further requirement for energy either as light or as adenosine triphosphate. The dependence for either light or exogenous adenosine triphosphate became apparent, however, when ribulose diphosphate or phosphoenolpyruvate were replaced in the reaction mixture by ribose-5-phosphate or pyruvate.

Typical results, shown in Table 3, indicate that in the presence of ribose-5-phosphate, a marked increase in carbon dioxide fixation was observed in the light when adenosine diphosphate and inorganic phosphate were added to the reaction mixture. The addition of adenosine diphosphate made photosynthetic phosphorylation by chromatophores possible and thus supplied adenosine triphosphate to the reaction mixture. In the dark, a similar increase in carbon dioxide fixation occurred on adding exogenous adenosine triphosphate. The main product of carbon dioxide assimilation, aspartate, was the same in the light as in the dark with exogenous adenosine triphosphate (Fig. 3).

Table 3. EFFECT OF LIGHT AND ADENOSINE TRIPHOSPHATE ON CARBON-14 DIOXIDE FIXATION BY CELL-FREE PREPARATIONS OF *Chromatium* IN THE PRESENCE of RIBOSE-5-PHOSPHATE

Treatment	Total $^{14}CO_2$ fixed in soluble compounds (counts × 1,000/min.)
1. Dark, control	54
2. Dark, ATP, R-5-P omitted	48
3. Dark, ATP	138
4. Light, control	54
5. Light, ADP + P	108

Each vessel contained in a final volume of 1·5 ml.: cell-free extract, containing 0·3 mgm. bacteriochlorophyll and the following in μmoles: *Tris*, *p*H 7·8, 80; cysteine 20; magnesium chloride, 5; manganese chloride, 2; potassium chloride, 20; carbon-14 bicarbonate, 10; ribose-5-phosphate (R-5-P), 5; and, when added, adenosine diphosphate (ADP), 0·5; orthophosphate (P), 5; and adenosine triphosphate (ATP), 4. Other experimental conditions as in Table 1.

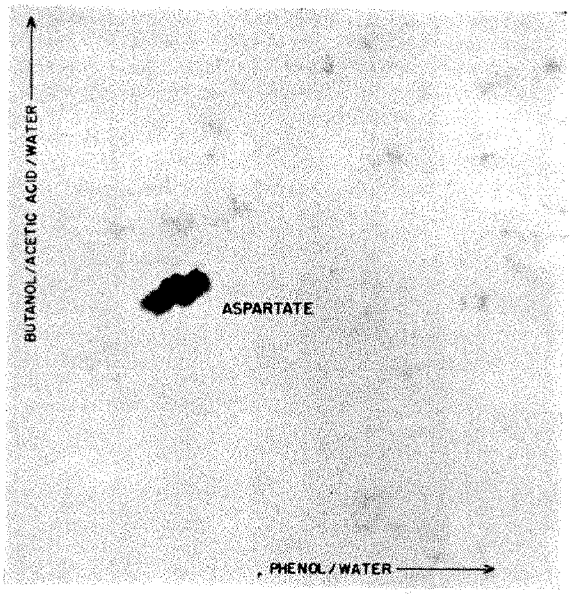

Fig. 3. Radioautograph of a chromatogram showing the soluble products of carbon-14 dioxide fixation in the *dark* by a cell-free preparation of *Chromatium* in the presence of ribose-5-phosphate and added adenosine triphosphate. Experimental conditions as in treatment 3 of Table 3. The same pattern of carbon dioxide fixation was obtained in the light without added adenosine triphosphate

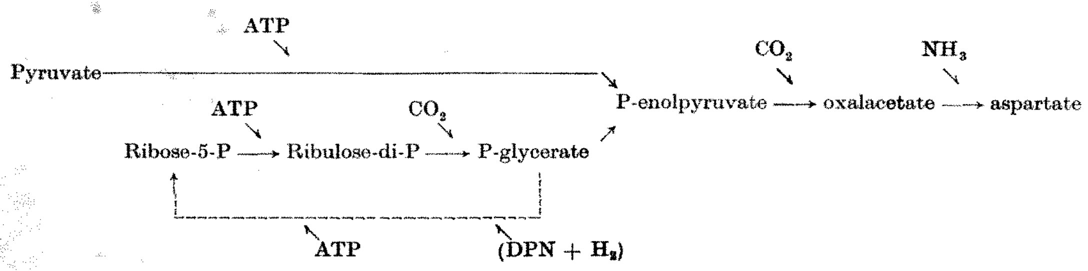
The equivalence of light and adenosine triphosphate was also observed when pyruvate was used as a carbon dioxide acceptor. The bacterial preparations were found to have a very active enzyme catalysing an exchange reaction (cf. ref. 24) between the carboxyl group of pyruvate and carbon-14 dioxide. The exchange reaction itself was independent of light or adenosine triphosphate, but carbon-14 dioxide fixation into aspartate and other dicarboxylic acids occurred only when light or adenosine triphosphate was present. For example, in the presence of pyruvate, carbon-14 dioxide, and exogenous adenosine triphosphate the main radioactive compounds formed (Fig. 4) were aspartate and pyruvate (by the exchange reaction). Other identifiable compounds were alanine, malate and fumarate. The formation of malate was in agreement with the presence in *Chromatium* extracts of the malic enzyme reported by Sisler and Fuller[25] and confirmed by us in other experiments[26].

A 'photosynthetic' pattern characteristic of *Chromatium* was also obtained without either light or exogenous adenosine triphosphate, in the presence of 3-phosphoglycerate or phosphoenolpyruvate as carbon-14 dioxide acceptor. The prominence of aspartate as the product of carbon-14 dioxide assimilation via the phosphoenolpyruvate carboxylation is illustrated by Table 4.

The pathway of carbon dioxide assimilation in *Chromatium*, which is now documented by these and other experiments[26] with cell-free preparations, either in light or in dark with exogenous adenosine triphosphate, is summarized below. The diagram shows the regeneration of ribose-5-phosphate from phosphoglycerate. We found in *Chromatium* extracts an active diphosphopyridine nucleotide-linked triose phosphate dehydrogenase, the enzyme which accounts for the reduction of phosphoglycerate that is involved in this step.



Assimilation of Acetate by Cell-free Preparations

The assimilation of acetate by cell-free preparations confirmed and extended the conclusions drawn from the acetate experiments with whole *Chromatium* cells. As shown in Table 5, in the presence of coenzyme *A*, acetate assimilation was greatly increased by light and by the addition of acetate 'acceptors', namely, oxalacetate or pyruvate.

Table 6 shows that the role of light was specifically concerned with the formation of adenosine triphosphate. Acetate assimilation occurred also in the dark, but only when exogenous adenosine triphosphate was added. No significant assimilation occurred when adenosine triphosphate was either omitted or when it was made unavailable for acetate assimilation by being trapped, in the light or in the dark, by a hexokinase–glucose system. These results, as well as the response from added coenzyme *A*, suggest that the role of light in acetate assimilation by *Chromatium* is to provide adenosine triphosphate that is required for the formation of acetyl–coenzyme *A*.

Table 4. PROPORTION OF ASPARTATE IN SOLUBLE PRODUCTS OF CARBON-14 DIOXIDE ASSIMILATION BY CELL-FREE PREPARATIONS OF *Chromatium*

Treatment	Per cent of $^{14}CO_2$ fixed as aspartate
1. Dark, pyruvate	15·7
2. Dark, pyruvate, ATP	50·1
3. Light, pyruvate, ADP + P	69·5
4. Dark, phosphoglycerate	40·0
5. Dark, phosphoenolpyruvate	81·0

The reaction mixture common to all treatments was that given for treatment 4 in Table 3, except that ribose-5-phosphate was omitted and the following additions were made (in μmoles) where indicated: pyruvate, 5; phosphoglycerate, 5; phosphoenolpyruvate, 4; adenosine triphosphate (ATP), 4; adenosine diphosphate (ADP), 0·5; and orthophosphate (P), 5.

Table 5. EFFECT OF LIGHT, OXALACETATE AND PYRUVATE ON THE ASSIMILATION OF CARBON-14-ACETATE BY CELL-FREE PREPARATIONS OF *Chromatium*

Treatment	Carbon-14 fixed in soluble compounds (counts × 1,000/min.)
Dark, control	5
Light, control	42
Dark, oxalacetate	42
Light, oxalacetate	300
Light, control	27
Light, pyruvate	75

The reaction mixture common to all treatments was that given for treatment 1 in Table 3, except that ribose-5-phosphate and carbon-14 bicarbonate were omitted and 0·3 μmole of coenzyme *A* and 3 μmoles of carboxyl-labelled carbon-14 acetate was added. 10 μmoles each of oxalacetate or pyruvate was added where indicated.

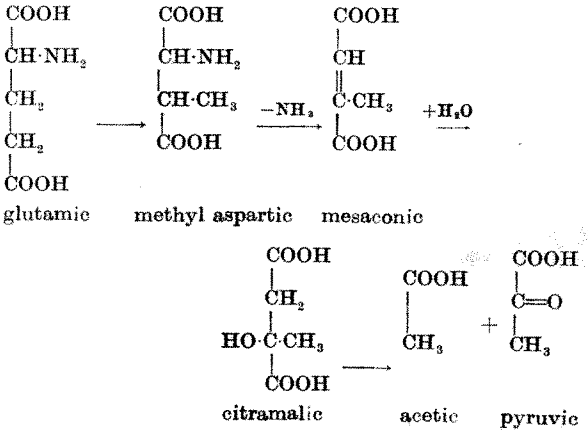
In cell-free preparations, as in whole cells, acetate was assimilated to glutamate. The investigation of glutamate synthesis from acetate revealed the presence in *Chromatium* of certain new synthetic pathways that have not been found in chloroplasts. *Chromatium* preparations, like chloroplasts (unpublished data), are able to activate acetate by converting it to acetyl-coenzyme *A*, and condensing acetyl-coenzyme *A* with oxalacetate to give citrate. Citrate is then converted via *iso*citrate and α-ketoglutarate to glutamate. Unlike chloroplasts, *Chromatium* preparations also condense acetyl–coenzyme *A* with glyoxylate[18,25] and, as we have now found with α-keto acids, pyruvate (reaction 1) and its analogue, α-ketobutyrate (reaction 2):

pyruvate + acetyl coenzyme *A*→ citramalate (methyl malate) (1)

α-ketobutyrate + acetyl coenzyme *A*→ethylmalate* (2)

* The compound has been isolated but not yet unequivocally identified.

Of the newly found condensations, the one of special interest was that of citramalate since Barker *et al.*[28] have shown that in *Clostridium tetanomorphum*, another obligate anaerobe, the citramalate pathway provides a mechanism for the degradation of glutamate to pyruvate and acetate:



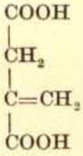
It now appears that in *Chromatium* the reversal of the degradative citramalate pathway may lead to

Table 6. EQUIVALENCE OF ADENOSINE TRIPHOSPHATE (ATP) AND LIGHT IN THE ASSIMILATION OF CARBON-14-ACETATE BY CELL-FREE PREPARATIONS OF *Chromatium*

Treatment	Carbon-14 fixed in soluble compounds (counts × 1,000/min.)
1. Dark, control	27
2. Dark, ATP	180
3. Dark, ATP, hexokinase	186
4. Dark, ATP, hexokinase, glucose	6
5. Light, control	414
6. Light, hexokinase	348
7. Light, hexokinase, glucose	20

Experimental conditions as in the oxalacetate treatments in Table 5. 1·5 mgm. hexokinase, Type III (Sigma Chemical Co.) and 10 μmoles glucose were added where indicated.

glutamate synthesis. Among the products of pyruvate condensation with acetyl-coenzyme *A*, we have identified citramalate and glutamate and another compound, which at first seemed to be mesaconate, but turned out to be the closely related itaconic acid (it may be noted that the R_F value for citramalate resembles that of compound *X* which Glover *et al.*[29] reported as the main product of acetate assimilation in *R. rubrum*):



$$\begin{array}{l}\text{COOH}\\ |\\ \text{CH}_2\\ |\\ \text{C}{=}\text{CH}_2\\ |\\ \text{COOH}\end{array}$$

itaconic acid

When oxalacetate was the acetate acceptor, the main products, that is, citrate and glutamate, were the same in light as in the dark with added adenosine triphosphate (Fig. 5). With pyruvate as the acetate acceptor the main products of acetate assimilation, either in light or with added adenosine triphosphate in the dark, were citramalate and glutamate (Fig. 6).

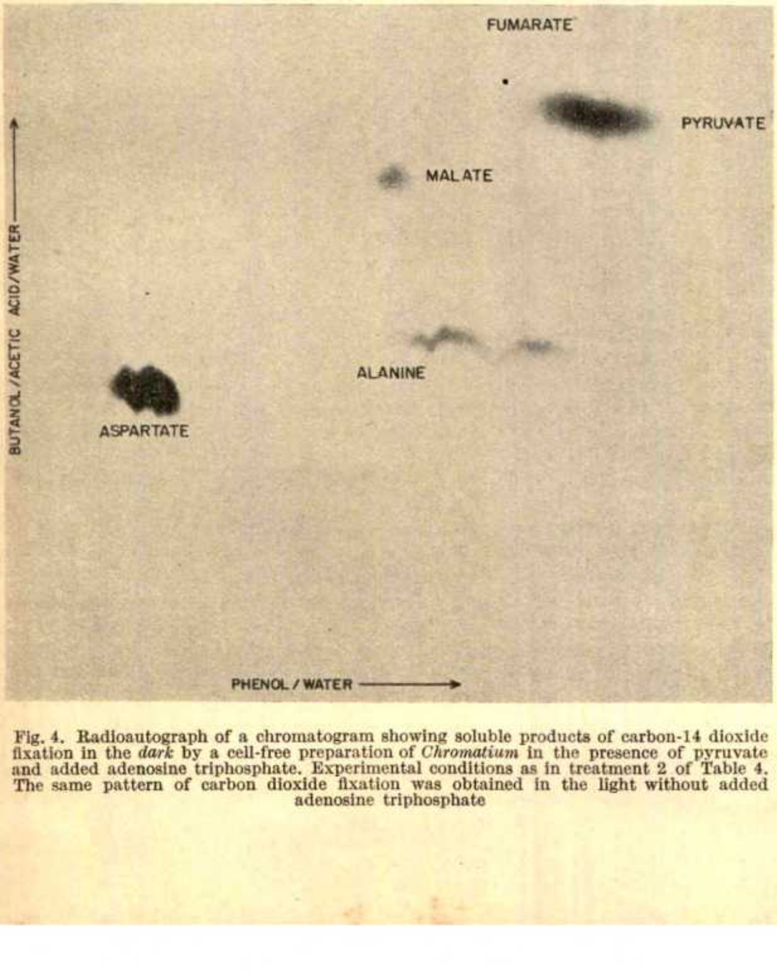


Fig. 4. Radioautograph of a chromatogram showing soluble products of carbon-14 dioxide fixation in the *dark* by a cell-free preparation of *Chromatium* in the presence of pyruvate and added adenosine triphosphate. Experimental conditions as in treatment 2 of Table 4. The same pattern of carbon dioxide fixation was obtained in the light without added adenosine triphosphate

The reactions of carbon assimilation in *Chromatium*, for which there is now experimental evidence, are summarized in Fig. 7. Most of the component reactions have already been discussed. In this scheme the only contribution of light (except perhaps in the photo-production of hydrogen[30]) for both carbon dioxide and acetate assimilation is in the formation of adenosine triphosphate. Carbon dioxide assimilation is shown in Fig. 7 to be dependent on exogenous hydrogen, whereas the assimilation of acetate by the citrate or citramalate pathway indicated yields hydrogen for metabolic purposes in accordance with the overall equation 3 or 4:

$$3\ \text{acetate} + \text{NH}_3 \underset{\text{(citrate pathway)}}{\xrightarrow{5\ \text{ATP}}} \text{glutamate} + \text{CO}_2 + 6\text{H} \qquad (3)$$

$$3\ \text{acetate} + \text{NH}_3 \underset{\text{(citramalate pathway)}}{\xrightarrow{4\ \text{ATP}}} \text{glutamate} + \text{CO}_2 + 6\text{H} \qquad (4)$$

Further evidence for the reactions shown in Fig. 7 will be given elsewhere[26].

Concluding Remarks

The similarity between the carbon assimilation patterns of cell-free systems supplemented with adenosine triphosphate in the dark, and those found in whole cells of *Chromatium* in the light, provides, in our judgment, significant evidence that in this obligate phototroph exogenous adenosine triphosphate is equivalent to light. The role of adenosine triphosphate, whether formed by photosynthetic phosphorylation or supplied from without, was twofold. Adenosine triphosphate was either required for the formation of an 'activated' substrate (ribulose diphosphate, phosphoenolpyruvate or 1,3-diphosphoglycerate) for a subsequent carboxylation or reduction, or it was required for the formation of an 'activated' carbon source, as by forming acetyl-coenzyme *A* from acetate and coenzyme *A*. The activated compounds are then ready for participation in the synthetic reactions that are catalysed by specific enzyme systems, all of which function in the dark.

In this view of photosynthesis, carbon dioxide assimilation, although quantitatively the dominant form of photosynthesis on the Earth, is fundamentally only a special case of the use of light energy. It was previously suggested[5] that even in green plants, light energy, when converted to adenosine triphosphate, may be used for driving endergonic reactions other than carbon dioxide reduction. Experimental evidence

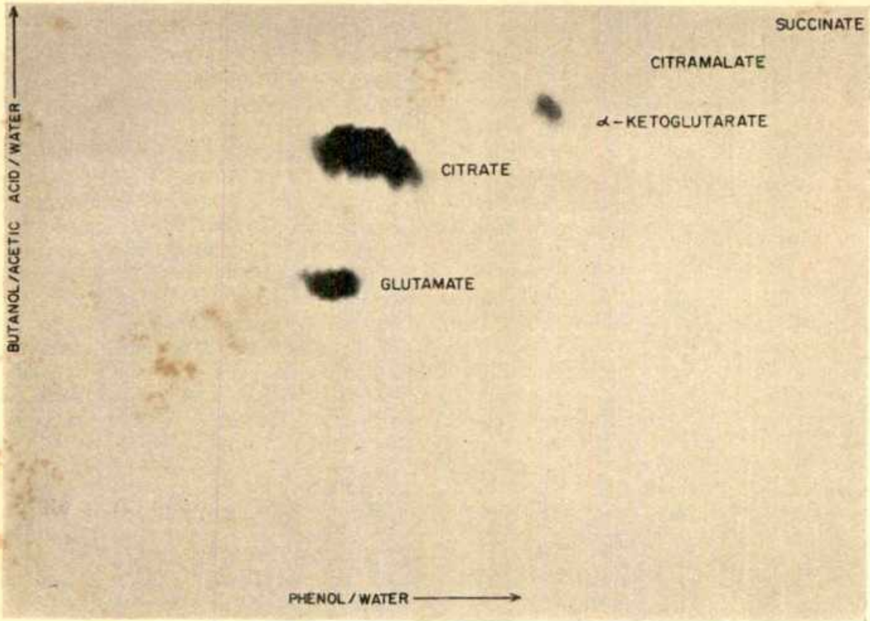

Fig. 5. Radioautograph of a chromatogram showing products of carbon-14-acetate assimilation in the *dark* by a cell-free preparation of *Chromatium* in the presence of adenosine triphosphate, coenzyme *A* and oxalacetate. Experimental conditions as in treatment 2 of Table 6. The same pattern of acetate assimilation was obtained in the light without added adenosine triphosphate

for this has recently come from the work of Maclachlan and Porter[31].

In the case of photosynthetic bacteria, carbon dioxide assimilation may, in certain circumstances, not even be the principal pathway for using the converted light energy for the synthesis of organic compounds (cf. ref. 14). As was shown here, *Chromatium* is able to assimilate acetate directly without an external source of carbon dioxide, either with the aid of light or with exogenous adenosine triphosphate. In this instance, therefore, the photo-assimilation of acetate is a case of photosynthesis without either carbon dioxide assimilation or oxygen evolution. In the conventional view of photosynthesis this state of affairs would be inadmissible, but according to the present concept the photo-assimilation of acetate by *Chromatium* constitutes photosynthesis because it involves biochemical syntheses that are being driven by light energy after it has been converted into adenosine triphosphate.

Carbon dioxide assimilation, in any event, in both green plants and photosynthetic bacteria, consists of exclusively dark reactions that are not peculiar to photosynthesis. It was already anticipated by Benson and Calvin, that "it is not to be expected that this type of work (investigation of the carbon cycle) will lead directly to a solution of the unique problems of photosynthesis, namely, the knowledge of the act or acts by which electromagnetic energy is transformed into chemical energy"[32]. The discovery of photosynthetic phosphorylation has since provided evidence that this transformation of energy is more closely linked with phosphorus than with carbon assimilation.

The photo-assimilation of acetate by *Chromatium* with the aid of adenosine triphosphate formed by light supports the suggestion made earlier[5], that, if in the early period of evolution of life forms, organic compounds were abundant and the Earth's atmosphere was a reducing one[33], then the light-dependent mechanism for adenosine triphosphate formation was

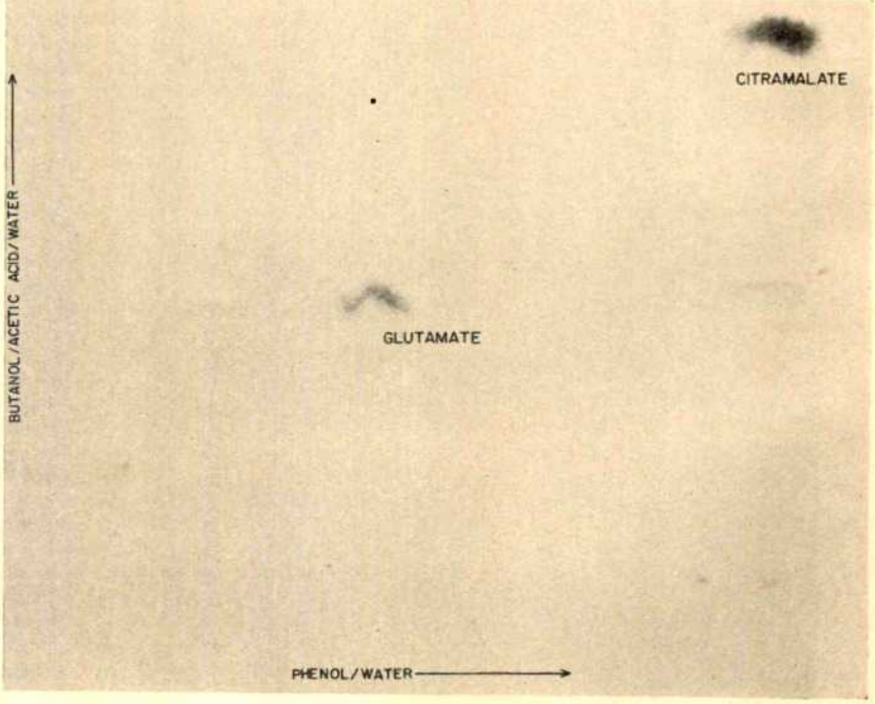

Fig. 6. Radioautograph of a chromatogram showing products of carbon-14 acetate assimilation in the *dark* by a cell-free preparation of *Chromatium* in the presence of adenosine triphosphate, coenzyme *A* and pyruvate. Experimental conditions as in treatment 2 of Table 6, except that pyruvate (5 μmoles) replaced oxalacetate, the gas phase was air, and chromatophores were removed from the cell-free preparation by centrifugation. The same pattern of carbon-14 acetate assimilation was obtained in the light, in the presence of chromatophores, without added adenosine triphosphate

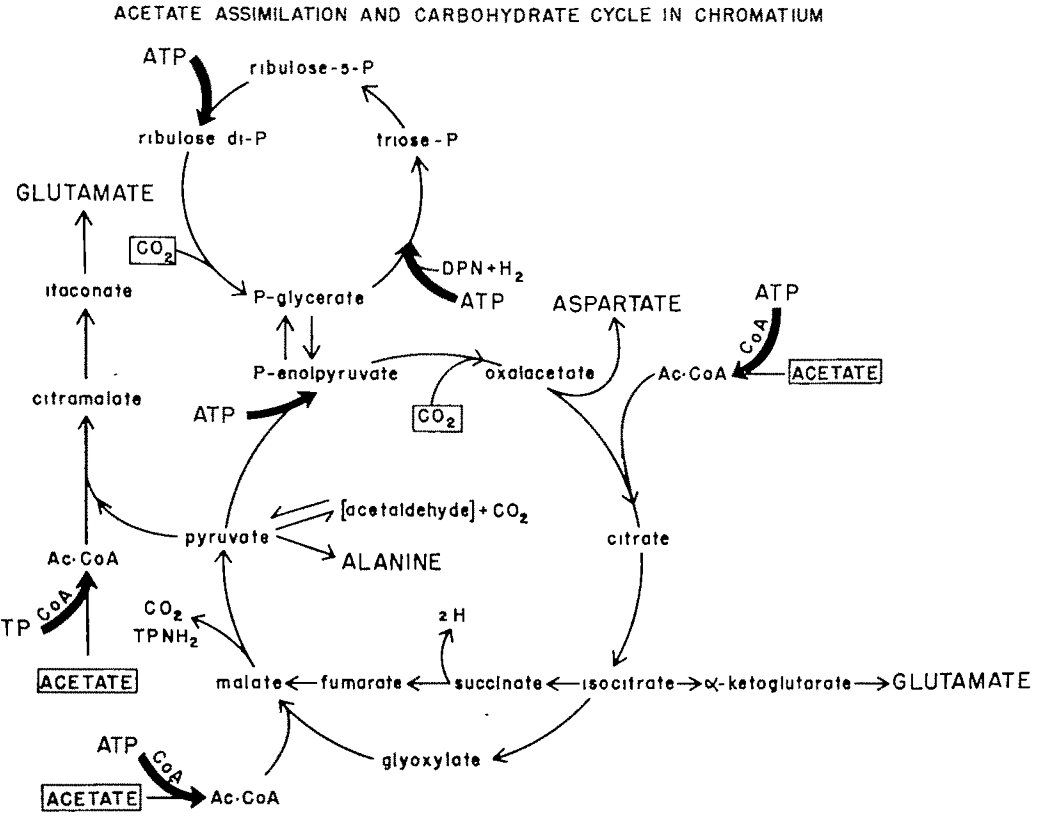

Fig. 7. Reactions of carbon assimilation in *Chromatium*. Further details are given in the text

the most important event for the newly emerging photosynthetic organisms. In this view, an obligate anaerobic phototroph such as *Chromatium* would represent the most primitive type of photosynthesis, one in which no oxygen is evolved, organic compounds serve as carbon sources and the main contribution of light is the formation of adenosine triphosphate. This primitive type of photosynthesis, it seems reasonable to suppose, was paralleled by transitional types in which the contribution of light was still the formation of adenosine triphosphate, but carbon dioxide was an important source of carbon, and the carbon dioxide reductant, reduced pyridine nucleotide, could be formed by dark reactions as, for example, with hydrogen gas. Finally, in the most advanced type of photosynthesis, carbon dioxide became the sole carbon source and the function of light was to provide both adenosine triphosphate and reduced pyridine nucleotide. Only in the last case, typified by green plants, when photosynthesis became strictly dependent on water for pyridine nucleotide reduction by light did oxygen evolution form an inseparable part of photosynthesis, as is envisaged by the electron-flow mechanism proposed elsewhere[3].

It would thus appear that oxygen evolution, which gave Priestley[14] almost two hundred years ago the first clue to the existence on this planet of what we now call photosynthesis, is, in the evolutionary time scale, the most recent aspect of the process (cf. van Niel, ref. 17). Photosynthetic bacteria, which have greatly contributed to our understanding of photosynthesis by showing that this process can occur without oxygen evolution[17], now also provide us with evidence that photosynthesis can occur without carbon dioxide assimilation. What remains fundamental to all photosyntheses is the conversion of light into chemical energy. This conversion appears to be intimately bound to photosynthetic phosphorylation and its product adenosine triphosphate, which is the universal 'energy currency' of all cells, whether they live in the light or in the dark.

This investigation was aided by grants from the National Institutes of Health and the Office of Naval Research.

OBITUARIES

Prof. W. E. Garner, C.B.E., F.R.S.

THE news of the death of Prof. W. E. Garner at his home in Bristol on March 4 was received with much sadness by his former colleagues at the University of Bristol, and particularly by those who had the privilege of working with him and under his leadership.

Garner was a man of great charm and kindness who won the affection and admiration of all who came into contact with him. His unselfishness and sincerity made him the most likeable of men. He was quiet, unobtrusive, entirely devoid of personal ambition and devoted to his work, whether it be in his laboratory, the councils of the University, or in the committee room. But these unassuming qualities did not obscure the greatness of the man. He was an enthusiastic and inspiring leader of research: keenly critical in scientific matters, yet very kindly and tolerant in his attitude to the ideas of others. Always most conscientious in the discharge of his duties, he maintained the tradition of lecturing to first-year students and he liked to know the students personally. The wide circle of friends, students and of many others who sought his advice and received it, valued a friendship which will endure as a cherished memory of a lovable character.

Garner was a student of the University of Birmingham, where he carried out research with Prof. P. F. Frankland. He was awarded an 1851 Exhibition in 1913 and proceeded to the University of Göttingen to work with Prof. Gustav Tammann. His work there was interrupted by the outbreak of the First World War, and on his return to England he worked at Woolwich Arsenal with Sir Robert Robertson on the calorimetry of high explosives.

On leaving Woolwich, Garner was appointed assistant lecturer in the University of Birmingham (January 1919) and assistant lecturer at University College, London (October 1919). From that time began a close and happy association with Prof. F. G. Donnan and a fruitful period of research.

In 1927, Garner was appointed to the Leverhulme chair of physical and inorganic chemistry in the University of Bristol, a post which he held until his retirement in 1955.

During the Second World War he established an extra-mural research team in the University of Bristol under the Ministry of Supply to assist Government ordnance factories in research on explosives and munitions. The group continued until the end of the War, although Garner himself moved to Fort Halstead in Kent to become in turn superintendent of Chemical and Explosives Research, deputy chief, and later chief, superintendent of Armament Research in the Ministry of Supply. His wide knowledge, enthusiasm and wise guidance were of paramount importance to the war effort, and he was associated with many important developments in armaments and munitions. His services were recognized in 1946 when he was made C.B.E.

On the cessation of hostilities, Garner once again returned to Bristol and continued his fundamental researches with increasing vigour. He had a wide interest in, and keep knowledge of, many branches of physical chemistry, and his mental qualities were only fully employed when he was simultaneously developing many research lines. Broadly, his main contributions to physical chemistry fall into the following groups: (*a*) The study of explosive reactions in gases and the ionization and radiation from flames; notable among these researches was the discovery of the effect of small amounts of hydrogen on the radiation from carbon monoxide flames. (*b*) Heterogeneous catalysis and particularly the measurements of heats of adsorption. He and his colleagues in Bristol made outstanding contributions to the mechanism of adsorption on metals and metallic oxides, and he was a leader in applying the newer ideas of the physics of the solid state to the interpretation of heterogeneous reactions. (*c*) The kinetics of solid reactions. Garner's pioneering studies on the mechanism of the interface reactions and nucleation processes in solid reactions, and the development of suitable experimental techniques, constitute a chapter to the progress of a subject in which he was the acknowledged leader in Britain.

After his retirement in 1955 his continued interest in these topics and his freedom from other responsibilities enabled him to organize a symposium on chemisorption at Keele, Staffordshire, which was published by the Chemical Society, and to edit a large volume on the "Chemistry of the Solid State". Most of the contributors to the latter volume were his former students or close scientific colleagues, and the book is very much a tribute to his work and inspiration.

Garner was a well-known figure at scientific gatherings, and scientific societies and Government committees made great calls upon his time. He was president of the Faraday Society (1945–47); a member of the Scientific Advisory Council of the Ministry of Supply for most of the period 1942–60, and also a scientific advisor for civil defence in the south-west region of Britain.

He received many honours: he was elected to the fellowship of the Royal Society in 1937; and was a Fellow of University College. He was well known abroad; he was an honorary member of the Polish Chemical Society, a corresponding member of the Patronato "Alfonso el Sabio", Madrid (1959), and a member of the Joint Services Mission to the United States and Canada in 1948.

C. E. H. Bawn

Prof. A. J. H. Goodwin

Astley John Hilary Goodwin was born in Pietermaritzburg on December 27, 1900, and died on December 5, 1959, after a long illness. The son of Canon W. A. Goodwin, he was educated at St. John's College, Johannesburg, and at the University of Cambridge, where he graduated in archæology. At the age of twenty-three he joined the staff of the University of Cape Town, serving there until his death. He was appointed associate professor in 1954 in recognition of his academic achievements and original work.

From the sixties of the nineteenth century, collectors had amassed considerable quantities of stone implements from large numbers of sites in southern Africa. Goodwin, on his return from Cambridge, first applied his mind to the problem of the systematic classification and chronological arrangement of this material and soon realized the need for a terminology that would be more applicable to the southern African facts than the European one hitherto accepted. He envisaged a subdivision of the Stone Age into three—Earlier, Middle and Later—each of which embraced a number of cultures and their variations. Collaboration with van Riet Lowe and Neville Jones led to the foundations of South African prehistoric classification being laid and to the elaboration of conjoint ideas in "The Stone Age Cultures of South Africa". This contained basic systematic descriptions and has been used as the foundation for prehistoric studies in both South and East Africa.

Goodwin stressed the need for a strictly scientific approach to field exploration and to the drawing of conclusions. His method of approach is to be found in his handbook entitled "Method in Prehistory". His own field-work was intensive and marked by meticulous accuracy of observation, whether it was concerned with the excavation of caves and shelters or with the examination of sequences of styles in rock engravings. Mainly undertaken within the confines of the Cape Province, his original field observations were supplemented by visits to many critical sites in other parts of Africa; and he excavated and studied important more recent archæological sites in Nigeria on the invitation of the Government of that country.

Goodwin's methodical and lively mind embraced many cultural interests and made him a good organizer. He took a leading part in founding the South African Archæological Society, was its secretary for a number of years, edited its *Bulletin*, and at the time of his death was its president. With A. L. du Toit he was enthusiastic in founding the Athenæum Trust, which provided a 'home' for the scientific and cultural societies, the headquarters of which are in Cape Town. For some years he served as the honorary general secretary of the Royal Society of South Africa and on its council and, again in the year of his death, was elected to its presidency. Whatever task of this nature he was called upon to perform, he carried it out with quiet unobtrusive natural efficiency and forthrightness; what he had to say was said quietly, succinctly and directly. Discussion with him was a pleasure, but acrimonious discussion was impossible. To all those who had contact with him he was "John".

Our late colleague is survived by his widow, a son and a daughter.

S. H. Haughton

Prof. C. J. Bakker

Prof. C. J. Bakker, whose death in an aeroplane accident in New York occurred on April 23, was on his way to attend a meeting of the American Physical Society in Washington. He had been invited to address the Society on recent researches at CERN and particularly on the successful operation of the 25-GeV. proton synchrotron.

Cornelis Jan Bakker was born in 1904 and studied physics under Zeeman in Amsterdam. After taking his doctorate (*cum laude*) in 1931 for original research on the Zeeman effect in the spectra of the noble gases, he spent a year in London at the Imperial College of Science and Technology continuing his work in spectroscopy. In the following year he joined the scientific staff of Philips, Eindhoven, where he worked on the physical problems of radio communications. His interests soon turned to nuclear physics and during the War, in collaboration with Prof. Heyn, he designed the Philips cyclotron. In 1946, he succeeded Gorter as professor of physics and director of the Zeeman Laboratory of the University of Amsterdam. He also became director of the Institute of Nuclear Physics, the focal point of Dutch nuclear research sponsored by Fundamental Onderzoek der Materie, by the City of Amsterdam and by Philips. He was a member of the Royal Netherlands Academy of Sciences.

In 1951, Prof. Bakker was invited by Prof. Auger, director of the Unesco Department of Natural Science, to be one of the eight experts charged with drawing up plans for the future European Organization for Nuclear Research (CERN).

At the first session of the Council of CERN during May 5–8, 1952, Prof. Bakker was appointed a member of the directorate and director of the Synchro-Cyclotron Division. On July 1, 1955, he became deputy director-general of CERN, succeeding Prof. Felix Bloch as director-general on September 1, 1955.

During the years 1955–60 CERN has grown from an idea put forward by a few European scientists to one of the best-equipped laboratories for high-energy nuclear physics research in the world. In 1957 the CERN 600-MeV. synchro-cyclotron was commissioned, and since that time it has been in full use as a nuclear physics research tool. More recently, at the end of 1959, the 25-GeV. proton-synchrotron came into operation at CERN.

In June 1957, Prof. Bakker received an honorary doctorate from the University of Geneva, and in April 1960 the Queen of the Netherlands awarded him the high honour of "Ridder in de orde van de Nederlandse Leeuw". His death took place before the official ceremony at which this award was to have been given.

Prof. Bakker believed firmly in European collaboration in science, and CERN, which is a unique and successful example of such collaboration, was inspired by his devoted leadership. His sudden death is a tragic loss to his wife and children, to CERN and to international scientific collaboration.

J. B. Adams

NEWS and VIEWS

J. H. Plummer Professorship of Experimental Physics at Cambridge: Prof. A. B. Pippard, F.R.S.

DR. A. B. PIPPARD, who has been elected to the John Humphrey Plummer professorship of experimental physics in the University of Cambridge, went to the Royal Society Mond Laboratory immediately after the Second World War, and in a series of elegant experiments on the high-frequency behaviour of metals at very low temperatures laid the foundations of much of his subsequent work. Observations on metals in the superconducting state led him to postulate a 'non-local' relation between superconducting current and magnetic field, which proved very suggestive in the later development of a fundamental theory by Bardeen, Cooper and Schrieffer. The study of normal metals brought not only a detailed understanding of the 'anomalous skin effect', first noticed by H. London, but also led Pippard to consider other aspects of the theory of metals, and he has recently been particularly concerned with the relation between the electronic structure of a metal and its physical properties. All his work has been distinguished by a remarkable combination of experimental skill with an ability to see his way through complicated theory in terms of simple physical concepts. This has enabled him not only to devise ingenious experiments but also to contribute effectively in fields which are usually regarded as the preserve of the professional theoretician. He was elected a Fellow of the Royal Society in 1956 and was awarded the Hughes Medal of the Society in 1959; his election to the John Humphrey Plummer chair at Cambridge is a well-merited recognition of his outstanding position in metal physics.

Physics at Southampton: Prof. G. W. Hutchinson

DR. HUTCHINSON, who has been appointed to a newly established second chair of physics in the University of Southampton, was educated at Abergele Grammar School and at St. John's College, Cambridge. After graduating in physics, he spent five years in industry and then, in 1947, started research in the Cavendish Laboratory under Prof. O. R. Frisch. He first investigated the properties of liquid argon as a conduction counter for nuclear particles, and, as a result, became interested in the analysis of pulse-height distributions. After trials of a number of systems Hutchinson realized the possibilities of computer techniques in this field, and working with G. G. Scarrott, devised in 1950 the pulse-height analyser which now bears their names. This elegant and powerful instrument represented a major advance in nuclear counting technique, and its widespread use was fitly recognized by the award of the Duddell Medal of the Physical Society to Hutchinson and Scarrott jointly in 1959.

Since 1952 Hutchinson has been Fellow and lecturer in the Department of Natural Philosophy, University of Glasgow, and lecturer and senior lecturer in the Department of Physics, University of Birmingham. His research interests have ranged widely, and include nuclear reactions at low energies, the proton–proton interaction at 1 GeV. and the origin of cosmic rays. Recently, he has been responsible for the experimental programme of the Birmingham proton synchrotron, and has developed techniques of fast counting and new forms of Čerenkov counter which have proved valuable for work with this machine. Hutchinson has always wished to extend his work through contact with the National Institute for Research in Nuclear Science, and his appointment to a chair in the University of Southampton at this time should help him to further his interests in high-energy physics.

The Advanced School of Automobile Engineering, Cranfield: Prof. J. R. Ellis

THE governing body of the College of Aeronautics has appointed Mr. John Romaine Ellis as professor of automobile engineering and first director of the Advanced School of Automobile Engineering being established at Cranfield in Bedfordshire, in association with the College of Aeronautics. Mr. Ellis graduated in mechanical and aeronautical engineering in the University of London in 1947, and was awarded a master's degree in 1954. He became an associate member of the Institution of Mechanical Engineers in 1952 and of the Automobile Division in 1958. During the period January 1944–December 1948, Mr. Ellis was employed successively at the Royal Aircraft Establishment and the Fairey Aviation Co., Ltd. In 1949 he joined the lecturing staff of the Royal Military College of Science, Shrivenham, first in the Materials and Structures Branch, and is at present principal lecturer in the Machines Branch. His published papers have dealt with wind-up in multi-axle drive vehicles, the effect of speed of rotation and torque on the effective rolling radius of a pneumatic tyre, and with torque converters. He is at present investigating the steering mechanics of the pneumatic tyre.

Chemistry at Queen Mary College, London: Prof. M. J. S. Dewar, F.R.S.

AFTER eight years as head of the Department of Chemistry at Queen Mary College, London, Prof. M. J. S. Dewar was appointed to the chair of organic chemistry in the University of Chicago, in October 1959. His stimulating personality and exceptionally wide scientific interests, ranging from physical theory to organic synthesis, produced striking developments in both teaching and research at Queen Mary College. Outstanding among his achievements, which led to his election to the fellowship of the Royal Society earlier this year, are his contributions to the molecular orbital theory of conjugated molecules, the synthesis of tropylium salts and new hetero-aromatic boron compounds, and the development and use of radio-spectroscopic techniques for nuclear quadrupole, electron spin, and nuclear magnetic resonance. His departure is a great loss to chemistry in Great Britain, but every good wish goes with him for success and happiness in the United States.

Prof. B. C. L. Weedon

DR. B. C. L. WEEDON has been appointed to the chair of organic chemistry at Queen Mary College, where he will take up his duties in October 1960. Dr. Weedon graduated with first-class honours at the Imperial College of Science and Technology, London, in 1942 and, after a year's research, joined the Dyestuffs Division of Imperial Chemical Industries, Ltd. In 1947, he returned, as a lecturer in organic chemistry, to the Imperial College where he collaborated with the late Sir Ian Heilbron and afterwards with Sir Patrick Linstead. He was awarded the Meldola Medal of the Society of Maccabæans and the Royal Institute of Chemistry for 1952, and became reader in organic chemistry in 1955. Dr. Weedon is well known for his distinguished work in the fields of natural and synthetic polyenes, carotenoids and vitamin A, terpenes, acetylenes, fatty acids, pigments and other constituents of algae, fungi and bacteria, and the reactions of organic compounds in molten alkali and at electrodes. He is co-author, with Sir Patrick Linstead, of "A Guide to Qualitative Organic Chemical Analysis", and this year became scientific editor of *Pure and Applied Chemistry*, a journal to be published by the International Union of Pure and Applied Chemistry. Dr. Weedon will be a source of great strength to the Chemistry Department at Queen Mary College in the period of expansion and development which undoubtedly lies ahead.

Commonwealth Scientific and Industrial Research Organization (Australia) Division of Entomology

Dr. Douglas F. Waterhouse has been appointed chief of the Commonwealth Scientific and Industrial Research Organization (Australia) Division of Entomology in succession to Dr. A. J. Nicholson, who has occupied the post for twenty-seven years. The Division of Entomology was one of the first Divisions formed when the Council for Scientific and Industrial Research was set up in 1926. Dr. Nicholson has been appointed to a C.S.I.R.O. research fellowship and will continue in the Division of Entomology his notable research in the field of animal populations. He was a foundation Fellow of the Australian Academy of Science and a member of its first Council, and has held the offices of secretary (1954–55) and vice-president (1955–57).

Dr. Waterhouse graduated with first-class honours and the University Medal from the University of Sydney in 1937. During the War he held the rank of captain in the Australian Army Medical Corps. He was awarded the degree of D.Sc. from his University in 1952, and in the following year he shared the David Syme Research Prize with Dr. F. J. P. Dwyer. He has made two trips overseas in connexion with his research work in insect physiology and toxicology, spending six months in Cambridge just after the War, and six months in New Haven, U.S A., during 1955–56.

Movements of Scientific Men

In a written answer in the House of Commons on May 19, the Minister of Education, Sir David Eccles, as representing the Minister for Science, stated that the Department of Industrial and Scientific Research is at present undertaking, in co-operation with industry, a series of combined technical and economic studies of particular industries of national importance designed principally to discover where additional scientific research and development effort can most usefully be applied. A question was also asked referring to the emigration to the United States of another member of the scientific team working the Jodrell Bank radiotelescope. Sir David stated that as regards investigation into the reasons for emigration of scientists, he had nothing to add to replies given on March 28 and April 14, when he had pointed out that the general problem had been under consideration for some years by the Advisory Council on Scientific Policy, and had stated that, while there were no complete statistics of scientists who had emigrated to the United States or Canada, in 1958 7 scientists were recruited in America by the Civil Service Commissioners and the Atomic Energy Authority and in 1959, 16 were so recruited. Many scientists go overseas purely for further education, and others obtained valuable experience with which they later returned to Britain. In Sir David's opinion, a scientist should not be denied such opportunities, nor does it seem feasible for Britain to provide in every field of science, facilities identical with those in the United States.

Industrial Research in the United States

The final results of surveys, conducted for the National Science Foundation by the United States Department of Labour, Bureau of Labour Statistics, of funds and personnel for industrial research and development in 1956 present a picture generally very similar in character to that shown in Britain by the recent report from the Department of Scientific and Industrial Research (Science and Engineering in American Industry—Report on a 1956 Survey. Pp. ix + 117. (NSF 59-50.) (Washington, D.C.: Government Printing Office, 1960.) 70 cents). There was an increase of 75 per cent in expenditure on industrial research and development in the period 1953–56 from 3,500 million dollars to 6,200 million, and in January 1957, 223,000 scientists and engineers and 396,000 other personnel were engaged in research and development. The Federal Government's contribution rose by 126 per cent to almost 3,000 million dollars and company-financed research and development increased by 45 per cent; in 1956 about 48 per cent of industrial research and development was Government-financed, compared with 37 per cent in 1953. In 1956 basic and applied research projects accounted for nearly one-fourth of the volume of research and development, basic research accounting for 244 million dollars and applied research for 1,200 million dollars. Manufacturing and other industries employed 728,000 scientists and engineers in all activities in January 1957, an increase of 28 per cent on January 1954, as well as 570,000 technicians, of whom 157,000 were employed in research and development. It is estimated that independent commercial laboratories, engineering service firms and trade associations spent more than 100 million dollars on research and development in 1956, and employed a further 5,000 engineers and scientists and 7,000 other personnel on such activities. The chemical industry spent about 55 million dollars on basic research in 1956 and the electrical equipment industry 50 million dollars, aircraft manufacturing coming third with 41 million dollars. Projects in engineering sciences accounted for about 30 per cent of the total cost of basic research and research in chemistry for another 30 per cent, but the most rapid growth in basic research was in the medical sciences, on which the chemical industry spent nearly 25 per cent of its basic research effort.

Haffkine Institute of Bombay

The annual report of the Haffkine Institute for 1958 (pp. iii + 56. (Bombay: Government Books Depot; London: High Commissioner for India, 1959.) Rs. 0.62; 1*s*. 1*d*.) records the supply of large amounts of typhoid vaccine to Ceylon and cholera vaccine to Thailand during epidemics, through the World Health Organization; the demand for cholera vaccine was unusually high, while that for plague vaccine continued to be low. Assistance was also offered in an epidemic of encephalitis, and influenza vaccine was prepared at the Institute and released for distribution. Research activities included investigation of the anti-coagulant action of cobra venom in human and horse blood, and the preparation of new chromogenic substrates for detection and location of enzymes in venom after separation by starch electrophoresis. New thiourea derivatives of the type R.SO$_2$.NH.CS.NH.R' were synthesized to study their anti-tubercular properties, and tolylbutylamide was prepared by desulphurizing N′-p-methylbenzenesulphonyl-N^3-n-butylthiourea with hydrogen peroxide. Various epidemiological features of salmonellosis are under study and also the pharmacological actions of cholera endotoxins with the view of determining the pathogenicity of the disease, while a gravimetric method has been developed for determining the halogen derivatives of 8-hydroxyquinoline commonly used in medical practice. Manufacture of cholera vaccine by the submerged culture method was attempted, and studies were continued on salivary glands of rabid animals, while trials of influenza vaccine in animals led to the development of a biological test for the standardization of the potency of the vaccine. A study of the iron-binding capacity of serum was started as well as further work on the nutritive evaluation of foodstuffs commonly consumed in the State of Bombay. A list of papers published during the year is included.

Bulletin of the Provisional International Computation Centre

The *Bulletin of the Provisional International Computation Centre*, the eighth issue of which has just appeared, is essentially a serial publication listing computing laboratories, facilities, and conferences throughout the world (Rome: Palazzo degli Uffici, Zona dell'UER, 1960). A few articles are printed from time to time, and the latest issue contains an account of electronic computing facilities in Czechoslovakia. Many of the machines described in this article are unfamiliar in the Western world, and it is to be hoped that fuller details may appear in future issues of the *Bulletin*. It is interesting, also, to read the paper, by Dr. J. E. Holmstrom, on his multilingual terminology project. This seeks to rationalize the computer vocabulary and, most appropriately, takes the new draft British standard on the subject as its basic material.

Comparative Biochemistry and Physiology

The first number of *Comparative Biochemistry and Physiology* (Vol. 1, No. 1 (January 1960). Pp. iv+100. Subscription rate (including postage): (A) For institutions, 20 dollars per volume; (B) for individuals, 15 dollars per volume. New York and London: Pergamon Press, 1960) contains a foreword by Dr. Joseph Needham, in which he points out that in the development of physiology and biochemistry, the emphasis has been on the study of man and the mammals because of the close association of these sciences with medicine. This journal, in which special attention is to be given to the comparative aspects of animal physiology and biochemistry, will help to increase knowledge of all types of animals. It should appeal to zoologists and marine biologists as well as to physiologists and biochemists. The first number contains, among others, communications on toads, fishes, worms, snails and insects. The editors are Dr. G. A. Kerkut, University of Southampton, and Prof. Bradley T. Scheer, University of Oregon, and there is an honorary editorial advisory board of distinguished scientists from many different countries.

Solvents and Dry Cleaning

Unlike laundries, which have been facing serious competition from washing machines and 'launderettes' for more than a decade, the dry cleaning business has been little changed by technical development. During the past twenty years the gross annual turnover of this growing industry has increased from £10,000,000 in 1939 to a probable £35,000,000 to-day. 43,000 people are employed in dry cleaning, two-thirds of them women, in about 2,000 separate companies. The industry handles nearly 400,000 garments a day, which represents about three garments a year for every man, woman and child in Britain. In a dry-cleaning establishment the cleaning liquids are organic solvents, either petroleum-derived white spirit or chlorinated hydrocarbons, such as perchlorethylene. While solvents alone will release and carry away much of the dirt held in the fibres by greasy matter, they make little or no impression on water-soluble sugar and food stains. The advent of the steam gun has speeded up what is called the 'spotting' process. The gun spurts a jet of steam on to the stains, softening them and knocking the food and other particles off the fibres of the garment. In the more modern charged system of cleaning, electronic controls are widely used and give a very high and consistent standard of cleaning. The subject is treated in more detail in *Catalyst* (Vol. 3, winter edition 1959–60).

Flora of the Belgian Congo

The ninth volume of the monumental "Flore du Congo Belge et du Ruanda-Urundi" has now been published by the Institut National pour l'Etude Agronomique du Congo Belge. In its format it follows the same lines as its predecessors. It contains the families Buxaceae, Anacardiaceae, Aquifoliaceae, Celastraceae, Hippocrateaceae, Salvadoraceae, Icacinaceae, Sapindaceae, Melianthaceae, Balsaminaceae, Rhamnaceae, Vitaceae and Leeaceae, some of which are both large and taxonomically complicated. Among the more noteworthy treatments are that of Anacardiaceae by P. Van der Veken, in which the largest genera are *Trichoscypha* with 20 species and *Heeria* with 10; the troublesome Sapindaceae, including 26 species of *Allophylus*, by Hauman; the revision of *Impatiens* by Wilczek and Schulze in which 35 species are enumerated; and the Vitaceae by De Wit and Willems in which the genus *Cissus* runs to no less than 95 species in addition to others imperfectly known. The Hippocrateaceae (which are maintained as distinct from Celastraceae) have been subjected to an elaborate revision by Wilczek. Thirteen genera are recognized, from which it will be seen that the increase in generic segregation in this family, as carried out in recent years by A. C. Smith for America and N. Hallé for Africa, is supported. The largest genus is *Salacia* with 54 species. Students of the family Melianthaceae will have to take notice of a new classification of the formidable genus *Bersama* differing considerably from that of Verdcourt published in 1950.

Health of the Executive

DURING the past six years the Diagnostic Clinic of the Graduate School of Medicine, University of Pennsylvania, has carried out investigations into the health of 2,000 executives from 70 firms (Medical Affairs, University of Pennsylvania. 1, No. 3, Spring, 1960). On their first examination in the Clinic, 40 per cent of these individuals were found to have previously unrecognized disorders and only 28 per cent were diagnosed as completely healthy; the remaining 31 per cent had had previous illness which currently had an adverse effect on their physical status. Of the newly discovered disease, 57 per cent was considered potentially serious, 34 per cent was minor in importance, and 9 per cent insignificant. Disease in the serious category increased with age. In those 40 years of age or under, only 38 per cent of the newly diagnosed disease was considered serious, while in those over 60 years it rose to nearly 70 per cent. The conditions occurring in the older age groups are as susceptible to treatment as are those in younger individuals. 54 per cent of the newly discovered disease was concentrated in only 13 per cent of the group. There is thus a healthy group of 28 per cent having no disease, either new or old, and 13 per cent of the group having more than half of all the disease found. This small 'disease prone' group is being further examined.

Rugby School Natural History Society

THE report of the Rugby School Natural History Society for 1959 contains a number of articles for which the boys concerned were awarded school prizes (Pp. 24+2 plates. Rugby: Rugby School Natural History Society, 1960). One of the most interesting is by I. H. R. Thompson, who obtained a distinguished-work prize. During a period of three years, Thompson has been collecting information about the disposal of dung and carrion and, in this article, describes the part played by beetles in dung and carrion disposal. Although four-footed scavengers and maggots play the greater part in disposal of carrion, Thompson shows that *Necrophori* beetles are responsible for the elimination of considerable quantities of carrion. Almost invariably, the beetles bury the corpses by excavating the earth under it and allowing the body to sink down into the hole. During burial the fur or feathers are usually removed, but the animal is never dissected. Beetles play a much larger part in the disposal of dung than they do of carrion. Although other agents, such as flies and worms, dispose of some dung, the bulk of it is dealt with by beetles. As early as March a patch of dung will yield a quantity of the smaller dung beetles, particularly the smaller *Aphodius*; by May the larger *Geotrupes* can be found in large numbers. About this time the smaller *Aphodius* appear in numbers again.

Population in 1958

THE second part of the Registrar General's Statistical Review, which used to be called "Civil Tables", is now published under the title "Tables, Population" (pp. xi+181. London: H.M. Stationery Office, 1960. 11*s*. 6*d*. net). The contents remain unchanged, however; mortality statistics continue to be published in the medical tables, and Part 2 of the volume for 1958 deals with births, marriages and total population. There have been no major changes in the presentation of statistics compared with previous years. Nor were there any striking new trends in the figures themselves during that period. Divorces continued to decline in numbers, new petitions filed stood at the lowest figure since 1945, when the married population was lower in absolute numbers than to-day. Live births were up by about 18,000 compared with the previous years, raising the birth-rate from 16·1 to 16·4 per thousand of the total population and the legitimate birth-rate from 111·5 to 113·9 per thousand married women of reproductive age. Births have been increasing steadily since 1955, and provisional figures for 1958 indicate that the rise has continued in that year.

Principles of the Extraction of Metals

MONOGRAPH No. 3 of the series being published by the Royal Institute of Chemistry for the guidance of teachers in schools is concerned with the application of physico-chemical principles to extraction metallurgy (Royal Institute of Chemistry Monographs for Teachers. No. 3: Principles of the Extraction of Metals. By Dr. D. J. G. Ives. Pp. vi+57. London: Royal Institute of Chemistry, 1960. 6*s*.). The author, Dr. D. J. G. Ives, has done a very good bit of work, and no better preparation for a prospective student of metallurgy could well be imagined. The first of the four chapters is concerned with the thermodynamical background, the reader being introduced to, or reminded of, the fundamental concepts. In the next, these are applied to pyrometallurgical processes. Chapter 3 gives a short account of the factors which govern the choice of extraction methods, and the booklet ends with a description of some typical operations such as roasting, the extraction of iron and copper and an outline of hydrometallurgy. This is an excellent introduction to the subject; the only question which can arise is whether the treatment may not be a bit too ambitious for its purpose, but this is a fault, if indeed it be one at all, which is easily remedied.

A Blood Parasite from the California Yellow-legged Frog

DURING the summer and early autumn of 1958, eleven *Rana b. boyli* were collected from Dutch Mill Creek, Sonoma County, California. Examination of the peripheral blood showed the presence of extra-cellular and intra-erythrocytic hæmogregarine-like parasites (considered to be *Karyolysus sonomae*) in five of the hosts. Sections and tissue impressions of the viscera indicated that the parasite underwent schizogony in endothelial cells. Donald L. Lehmann reports that this is the first authentic report of a species of this genus to be recorded from any group but the Reptilia (*Proceedings of the American Philosophical Society*, 103, No. 4; August 1959). Previous reports from the Amphibia have been based upon the morphology of the parasite in the peripheral blood and were not confirmed by demonstrating the vertebrate life-cycle.

The genus *Karyolysus* was established by Labbe (1894) to include those intra-erythrocytic sporozoans capable of fragmenting the nucleus of the host-cell. Reichenow (1921) found that this lytic activity was of uncertain generic worth; he did, however, demonstrate that the parasite could be distinguished from other hæmogregarine-like species on the basis of the life-cycle in the vertebrate host, where schizogony occurs in endothelial cells and the resulting merozoites, following their penetration into erythrocytes, develop into gametocytes. Infections were determined by staining thin smears of peripheral blood with Wright's stain, and more detailed observations were made following Giemsa's stain. Sections of viscera (liver, spleen, kidney, lung and heart) were fixed in alcohol–formalin–acetic acid, stained with Heidenhain's iron hæmatoxylin and cut 15 microns in thickness.

Factors affecting Tubers in *Begonia evansiana* Andr.

THIS species of *Begonia*, which is evidently a useful plant for investigations of developmental physiology, has buds which consistently form aerial tubers when exposed to short days. These tubers, when given sufficient short-day treatment, do not sprout when afterwards exposed to long days. However, if the plants are transferred to long days after a certain minimal short-day exposure, the tuberizing buds resume growth. There is evidence, from defoliation experiments, that the tuber may itself be sensitive to light (Esashi and Nagao, *Sci. Rep. Tohoku Univ.*, Ser. 4 (Biol.), 24, 81; 1958). These authors (*ibid.*, 25, 191; 1959) have now reported that aerial tubers of *Begonia evansiana* Andr., which are formed under short-day conditions, begin to sprout when isolated and exposed to continuous light while they are actively thickening. After the completion of thickening, however, the tubers sprout no more in response to light. These dormant tubers can be induced to sprout after low-temperature treatments. Whether or not the tubers sprout, they develop roots. In a study of the action of gibberellin on the dormancy of the tubers, Nagao and Mitsui (*ibid.*, 199) found that gibberellin treatments in the concentration range from 0·1 to 100 p.p.m. had no dormancy-breaking effect. Gibberellin treatments at concentrations of 10 and 100 p.p.m. inhibited the sprouting of aerial tubers. The gibberellin effect was greater in more dormant tubers. Gibberellin seemed to induce or prolong the tuber dormancy. The gibberellin-induced dormancy appeared to be broken by low-temperature treatments like natural dormancy. Rooting of aerial tubers was affected but slightly by gibberellin.

Rensselaer Polytechnic Institute

A REPORT on gifts, grants and bequests to Rensselaer, 1958–59, has been issued by the Rensselaer Polytechnic Institute as a supplement to the annual development report, and to emphasize the major importance of such assistance in helping the Institute to achieve its educational goals (pp. 16. Troy, New York: Rensselaer Polytechnic Institute, 1960). Without such contributions the Institute could neither survive nor establish firm plans for future growth. In the past fiscal year such gifts of cash and equipment amounted to 1,362,854 million dollars.

Summer School in Crystal Structure Determination

A SUMMER School in "Modern Methods of Crystal Structure Determination" will be held in the Manchester College of Science and Technology during August 29–September 9. The main topics to be dealt with, by lectures, practical work and discussions, will be direct methods, Fourier-transform and optical-transform methods, anomalous scattering, and refinement procedures. In addition, there will be some lectures and discussions on recent results in various fields, with assessment of their implications. The fee for the course will be £25, including accommodation in one of the University halls of residence. The fee for attendance without accommodation will be £5. Further information can be obtained from the Director, Extra-Mural Department, The University, Manchester 13.

Association of Consulting Scientists

AT the annual general meeting of the Association of Consulting Scientists, held in London recently, the following officers and Council for 1960–61 were elected: *chairman*, Dr. J. G. Davis; *hon. treasurer*, Dr. G. W. Ferguson; *hon. secretary*, Mr. W. H. Stevens; *other members*, Dr. M. Barent, Dr. H. H. Chambers, Dr. Julius Grant, Dr. J. H. Oliver, Mr. O. W. Roskill, Mr. F. G. Sarel Whitfield.

The Linnean Society of London

AT the anniversary meeting of the Linnean Society of London, held on May 24, the following were elected officers and Council for the session 1960–61: *president*, Prof. C. F. A. Pantin; *treasurer*, The Earl of Cranbrook; *secretaries*, Dr. C. R. Metcalfe (botany), Dr. H. G. Vevers (zoology), Dr. John Smart (editorial). *Vice-presidents* appointed were: Mr. E. J. H. Corner, The Earl of Cranbrook, Asst. Prof. H. R. Hewer and Dr. W. G. Templeman. *New members of Council*: Dr. A. J. Cain, Prof. A. R. Clapham, Dr. W. P. Crowcroft, Mr. F. C. Deighton and Mr. J. F. Levy. *Linnean Gold Medals* were presented to: Dr. Libbie Henrietta Hyman and Dr. H. Hamshaw Thomas. *The Trail Award and Medal* was presented to Dr. Laurence Ernest Rowland Picken. Prof. Dr. C. G. G. van Steenis and Dr. Robert E. Snodgrass were elected foreign members and Mr. H. F. Comber, Mr. Dennis A. Kempson and Prof. Alexander Eric Kohts were elected associates *honoris causa*.

Royal Society of South Africa

THE following were elected as officers and Council for 1960: *president*, Dr. S. M. Naudé; *honorary general secretary*, Mr. W. J. Talbot; *honorary treasurer*, Dr. N. Sapeika; *acting honorary editor of transactions*, Mr. A. M. Talbot; *honorary librarian*, Dr. J. H. Day; *other members of council*, Dr. R. A. Alexander, Dr. S. F. Bush, Dr. A. L. Hales, Dr. W. E. Isaac, Dr. M. R. Levyns, Dr. R. H. Marloth, Dr. S. H. Skaife, Dr. R. H. Stoy and Dr. C. L. Wicht.

The Leopoldina German Academy of Sciences: Elections

DIE Deutsche Akademie der Naturforscher, Halle, recently elected the following new members to the Sections indicated: *Astronomy*, Prof. Paul ten Bruggencate (Göttingen), Prof. A. A. Michailow (Pulkowo, Leningrad), and Prof. Martin Schwarzschild (Princeton); *Medicine*, Prof. Heinrich von Hayek (Vienna), Prof. Josef Kimmig (Hamburg), Prof. Friedrich Matzen (Leipzig), Prof. Hans Netter (Kiel), Prof. Karlheinz Sommer (Halle), and Prof. Werner Wachsmuth (Würzburg).

"Ataxia in Hens poisoned by Tri*para*ethylphenyl Phosphate"

WITH reference to her communication under this title in *Nature* of January 23, p. 247, Miss Ann Silver writes: "I should like to emphasize that the first evidence that this substance produces ataxia in hens was observed by Bondy, Field, Worden and Hughes at the Nutritional Research Station in Huntingdon, and it was first synthesized in the laboratories of Coalite and Chemical Products, Ltd., and the sample tested by me was provided by Dr. H. F. Bondy".

University News :

Belfast

THE following appointments to lectureships are announced: Dr. S. M. Nelson (organic chemistry); Dr. A. R. Johnston (physics); Dr. L. T. Threadgold (zoology); Mr. T. J. Black and Mr. D. McCloy (mechanical engineering).

Birmingham

THE title of reader in reactor physics has been conferred on Dr. J. Walker, senior lecturer in physics. Appointments to lectureships are as follows: Gillian Vaisey (civil engineering); G. Lees (road materials); Dr. G. H. Burkhardt (mathematical physics); Dr. M. J. Lawrence (genetics); G. H. Trengrouse and E. Amini (mechanical engineering); Dr. D. C. Champeney and D. A. O'Connor (physics). D. R. Milner has been appointed Lucas Fellow in metal-joining in the Department of Industrial Metallurgy for seven years.

Edinburgh

THE following have been appointed Imperial Chemical Research Industries Fellows: Dr. J. L. Holmes, Dr. K. R. Jennings, Dr. G. R. H. Jones, Dr. A. J. Charlson, and Dr. J. W. Sutherland. Mr. M. J. O'Hara has been appointed lecturer in geology and Mr. E. R. S. Fifoot, University librarian (as from October 1).

Leeds

APPOINTMENTS to lectureships are as follows: W. G. Collins and J. A. Fox (civil engineering); Dr. C. M. Reeves (electronic computing); C. G. Woods (pathology); Dr. P. J. Wyllie (experimental petrology). Dr. D. M. Robertson has been awarded the Portsmouth fellowship for research in multiple sclerosis for three years. The Department of Zoology has received a grant of £2,055 from the Department of Scientific and Industrial Research for research projects under the direction of Dr. Broadhead. The Department of Biomolecular Structure received grants of 152,517 dollars from the United States Public Health Authority and £1,100 from the Medical Research Council; the latter is to be used in establishing a research fellowship. The Houldsworth School of Applied Science has received among other grants £3,500 from the British Coke Research Association and £1,200 a year to establish a research fellowship in ceramics from the Thermal Syndicate, Ltd.

Nottingham

DR. CYRIL CLIFFORD ADDISON, at present reader in the Department of Chemistry, has been appointed professor of inorganic chemistry as from October 1. Dr. Addison graduated at Durham in 1934 and obtained the research degrees of that University of Ph.D. in 1937 and of D.Sc. in 1947. During the War he worked for the Ministry of Supply at Runcorn and Preston, and was later head of the Analytical Research Laboratories at Sutton Oak. He was appointed lecturer in inorganic chemistry at Nottingham in 1946, and in 1952 the title of reader was conferred upon him.

Dr. Maurice William Partridge, at present Lord Trent reader in pharmaceutical chemistry, has been appointed to the Lord Trent chair in the same subject as from October 1. Dr. Partridge graduated with honours at University College, Nottingham, and in 1941 was awarded the research degree of Ph.D. of the University of London. During the War he was research assistant to the British Pharmacopœia Commission and later was senior scientist in the chemical research laboratories of Boots Pure Drug Co., Ltd. He was appointed lecturer in pharmaceutical chemistry in 1947, and in 1955 was appointed to his present readership.

Oxford

THE following appointments to readerships have been announced: Dr. E. P. Abraham (chemical pathology); Dr. E. Bülbring (pharmacology); Dr. W. A. Waters (physical organic chemistry); and Dr. N. Kurti (physics).

St. Andrews

THE following appointments to senior lectureships are announced: Dr. Ann R. Sanderson, Department of Zoology, Queen's College; and Dr. D. V. Osborne, Department of Natural Philosophy, St. Salvator's College.

Announcements

LORD HIVES, who was the first chairman of the National Council for Technological Awards, has been given an honorary diploma in technology (engineering); this is the first honorary award to be made by the Council.

THE Chemical Research Committee of the Indian Council of Scientific and Industrial Research is organizing a two-day symposium on "Proteins" at Mysore during the first week of August. Further information can be obtained from Dr. A. Sreenivasan, Central Food Technological Research Institute, V. V. Mohalla, P.O., Mysore 2.

THE tenth International Congress of the History of Science will be held in the United States during August 26–September 2, 1962. Opening sessions of the Congress will be held at Cornell University, Ithaca, New York, and the concluding sessions will be held at the American Philosophical Society, Philadelphia, Pennsylvania. The president of the Congress is Prof. Henry Guerlac, of Cornell University. Further information can be obtained from the secretary, Prof. C. Doris Hellman, Cornell University, Ithaca, New York.

THE fourteenth congress of the International Scientific Film Association will be held in Prague during September 16–24, and will include, as in previous years, a festival of films on "Presenting Science". Responsibility for selecting the British film entry for the Congress rests with the Scientific Film Association of Great Britain. Further information can be obtained from the Scientific Film Association, 3 Belgrave Square, London, S.W.1.

AN international conference on "Natural Rubber Research", sponsored by the Rubber Research Institute of Malaya with the support of the Government of the Federation of Malaya and the Rubber Producers' Council, will take place in Kuala Lumpur during September 26–October 1. Further information can be obtained from the Rubber Research Institute of Malaya, P.O. Box 150, Kuala Lumpur.

NEW PHYSICS LABORATORY OF THE UNIVERSITY OF READING

THE new physics laboratory of the University of Reading was opened on May 17 by Sir George Thomson, who named the building "The J. J. Thomson Physical Laboratory". On the occasion of the opening, honorary degrees were conferred on Dr. T. E. Allibone, Prof. N. F. Mott, Prof. F. Seitz and Sir George Thomson. It is of interest to recall that Sir J. J. Thomson received an honorary degree from the University in 1935 and that both the first professor of physics at the University of Reading (J. A. Crowther) and the present professor (R. W. Ditchburn) worked in the Cavendish Laboratory under him.

The Laboratory was planned to accommodate undergraduate classes of up to 100 in each of the first two years (post-intermediate), and about thirty in the special honours final year. Facilities for about fifty research workers (including members of staff) were also provided. It was expected that the intermediate science class would be very small, but that teaching at this level would be required for about 100 students in agriculture, etc. It now appears probable that the numbers of students in these elementary classes will be much smaller than was expected, but the teaching laboratory space released will be required to deal with the large increase of students now predicted for the next decade.

The Laboratory is a three-storey steel-framed building with a floor area of about 63,000 sq. ft. The structure has brown-grey brick walls and the greater part has a low pitch roof covered in copper. The western end of the Laboratory, connected to the main building by a two-storey glazed link, is the lecture theatre block. This has a flat roof surrounded by a parapet wall. The ground floor contains two lecture theatres, with a projection room for each and a preparation room common to both. On the first floor, above the lecture theatres, are two large teaching laboratories for the general honours students and for special honours students in their first and second years. These laboratories cover an area of 5,000 sq. ft. with a single-span roof, internal steel partitions being used to provide dark-rooms, etc. The absence of internal structural pillars and load-

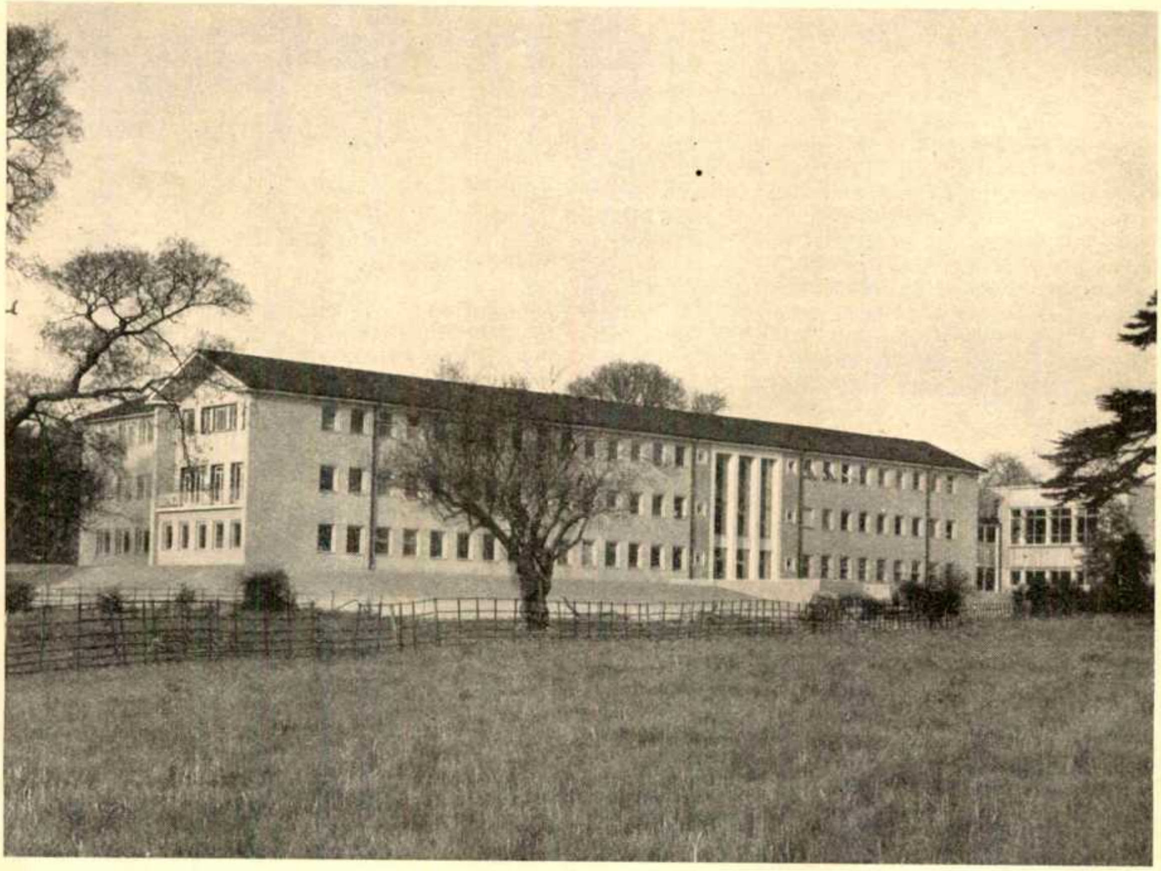

Fig. 1. The J. J. Thomson Physical Laboratory, University of Reading

bearing walls enables the space to be utilized in a very economical way.

The larger lecture theatre contains seating for 180 and the smaller for 105. Each has bench-type seating, specially modelled for maximum comfort, and fitted with hinged writing flaps. In each theatre the lecturer's demonstration bench is equipped with all laboratory services and, in addition, the electrically operated windows, blinds and dimming apparatus for the lighting can be controlled from it. The walls behind the demonstration benches are prepared to form a permanent projection surface 12 ft. wide and 6 ft. high, on which two pictures can be projected side by side. Below the projection surface is a 12-ft. glass chalk-board. On the left-hand side of the central wall is a splayed wall with a translucent glass chalk-board, which can be illuminated from behind when the room is darkened; on the right-hand side is another splayed wall fitted with a chalk-board of conventional type.

Heating in the lecture theatres is by means of radiant wall panels combined with a heated air plenum ventilation system. Elsewhere in the building heating is by 'Frenger' acoustic heated ceilings. All windows are double-glazed to reduce heat losses. Many of the rooms are provided with inlet and extract ventilation, particularly those fitted with dark blinds.

The main laboratory is planned on a repeating bay unit 7 ft. 6 in. wide and 16 ft. deep, with laboratory services arranged beneath the windows in a service rack. The services available in every bay of the building include alternating current supplies at 415 V. (3-phase) and 240 V. and 6 V. (single phase) and direct current at 240 V. and 24 V. Hot and cold water, gas and compressed air are also available.

It was estimated that one and a half million gallons of cooling water per annum would be required for diffusion pumps, compressors, etc., and a recirculation system is therefore provided. This service is generally available in the centres of rooms, together with 240 V. a.c. and one other service at choice.

Walls throughout the building are plastered and tinted and the doors are decorated in bright colours. The floors of most rooms are covered with 'Tarkett P.V.C.' tiles and the corridors with 'Korkoid'. The library has been designed to enable the beautiful surroundings of the Laboratory to be seen to advantage. Part of a gift from Imperial Chemical Industries, Ltd., has been used to provide books for the library, which will be especially useful during the next three years when the University Library is still on the old University site. Office accommodation for a theoretical physics group is provided near the library. This group is working on the application of quantum mechanics and statistical mechanics to problems in solid state physics, in particular crystal lattice vibrations, lattice imperfections and magneto-optic effects in semiconductors.

Most of the experimental work in the Laboratory is concerned with the physics of the solid state. One research group is studying the effects of imperfections in crystal structure on physical properties, particularly with reference to radiation damage (defects produced by irradiation with pile neutrons and other high-energy particles). A 2-MeV. Van de Graaff generator (purchased with a grant from the Department of Scientific and Industrial Research) is used to produce defects in a controlled way. It is housed in a small building at a convenient distance from the main laboratory.

A section of the research space is assigned to the radio-tracer laboratory, which is mainly concerned with atomic diffusion in metals. This laboratory contains also a mass spectrometer which is used to assist biological as well as physical research.

A research group, supported by the Admiralty, is working on the surface properties of semiconductors. Methods of breaking germanium in a very high vacuum (10^{-9}–10^{-10} mm. mercury) so as to expose a crystal plane have been devised, and the gradual contamination of these surfaces is being studied. Work on the etching of surfaces is being studied using high-quality optical microscopes, and an *E.M.*6 electron microscope is on order. Associated Electrical Industries, Ltd., have kindly agreed to provide a technical assistant to work this instrument for three years. Studies of solids by X-ray and electron diffraction are also in progress. The Royal Society has given a grant to assist the development of high-voltage electron diffraction using the Van de Graaff generator.

The Laboratory is equipped for spectroscopic studies for the infra-red, visible, ultra-violet and soft X-ray regions. The apparatus is used for measurements on solids chiefly in the infra-red and visible regions and in the vacuum ultra-violet. The results on gases have applications to studies on the upper atmosphere and to the physics of hot plasmas.

A biophysical investigation on vision is supported by the U.S. Public Health Service.

When the Laboratory was designed, the number of students in the University of Reading was expected to become stable at a figure in the range 1,500–2,000. An increase to 3,000 is now contemplated. The Laboratory will have to provide for larger numbers in the Physics Department and also for the early development of at least two new departments in the physical sciences. The design of the building provided for possible extension which, it was thought, might be needed after twenty-five years. The new conditions have led to discussion of this extension even before the building was opened.

R. W. DITCHBURN

GOVERNING TECHNICAL COLLEGES

A HANDBOOK, "The Technical Colleges and their Government", issued by the Joint Federation of British Industries Technical Colleges Committee under the auspices of the Federation's Education Committee, provides a concise but keen industrial appraisal of the structure of technical education, its historical background, academic pattern and finance as well as a close discussion of the government of technical colleges (pp. vii+44. F.B.I. Handbook. London: Federation of British Industries, 1960. 5s.).

Appendixes included a policy statement on the finance of advanced sandwich courses issued by the Federation, the Ministry of Education's Circular 7/59 on Governing Bodies for Major Establishments, and a selected bibliography which is thoroughly representative.

The recommendations based on this survey emphasize that it is the function of governors to ensure that their college fulfils its role as an academic institution within the national and regional framework of further education. To do so involves strong links with industry, commerce and the professions; a constant awareness of the changing needs of their students; and adequate powers to implement the governing body's decisions. Governors nominated by special interests can and should bring their special experience or background to bear on the affairs of the college, but the handbook emphasizes that the governors serve to promote the interests of the college and that they should be aware that each college occupies a distinct place in the pattern of further education as a whole.

On size, the handbook suggests a membership of about twenty as ideal, and it should include members of the professions with which the college is mainly concerned and of the universities. The contribution which headmasters of secondary schools could make should be considered and provision for co-opting independent persons with special knowledge or experience, representative of ex-students and for continuity is recommended. Stress is laid on the importance of the full implications of the recommendations of the Ministry of Education in regard to the powers of the governing body, and the handbook stresses the importance both of the power of governors being commensurate with the responsibilities they are asked to assume and of adjusting procedure to ensure the best possible use of the governors' time.

One meeting of two to three hours a term is suggested as covering most requirements, but apart from attendance at formal meetings of the governing body and its committees, governors can and should play a valuable part in the life of the college, and it is recommended that they should be encouraged to do so. Departmental advisory committees are usually appointed for each major discipline studied at a college, and these should consist of experts from industry or commerce, members of the governing body and the teaching staff and representatives of the appropriate professional body. They may also include H.M. Inspectors and should have room for co-opted independent experts. Close links between the advisory committees and the governing body are essential, but the constitutional position of advisory committees will vary according to the subject, and in fields which are undergoing continuous change, the establishment of permanent advisory committees may be advisable.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

THE South-Eastern Union of Scientific Societies held its sixty-fifth annual congress in Ipswich, during April 22–25, under the presidency of the Earl of Cranbrook. The headquarters of the congress was at Ipswich School, where an exhibition of natural history was on display. A young naturalists' evening was arranged and questions from the audience were answered by a panel under the chairmanship of Maxwell Knight. Lord Cranbrook's presidential address to the Union was on "East Anglian Mammals", and he began by explaining that most of the area is highly cultivated, therefore the habitats are largely man-made. The red deer in East Anglia are possibly the progeny of escapes of those introduced from Scotland and are larger than those of the same species in Scotland, the increased size being due to an environmental change. Introduced roe deer are now flourishing in the Breckland.

Dealing with the seal population he said that both common and grey species occurred, a colony of grey seals being established during 1958 on Grove Sands, off Yarmouth, which are dry at the high-water mark. Ringing experiments are being made for recording movements of individuals, breeding places and the months on which the young of different species are born.

Lord Cranbrook said that for some obscure reason there appeared to be a natural barrier on the Essex-Suffolk border which prevented a number of mammals from crossing to suitable habitats in Norfolk and Suffolk. The distribution of the dormouse, horse-shoe bat and grey squirrel is limited to the south of the Stour valley although the red squirrel is abundant in the coniferous woods of the Breckland. Coypu numbers increase and the animal has become a nuisance, damaging farm crops and banks of ditches and streams. Scientific investigation is necessary to find the steps to be taken for control. Defending the policy of the Forestry Commissioners in planting mainly conifers, he said that pine forests are useful for the preservation of mammals, badgers are increasing in numbers, and the pine marten, which is increasing its range, may be expected to reach the area in the near future. The question of the black rat race in the Fens needs careful consideration; there appears to be two varieties common in the south and east of England and their control may be necessary. He concluded his address by comparing the growth of teeth of the field and water voles. In the former the teeth continue to grow throughout their life, as much as 2½ in. a year, a corresponding amount being worn away by the hard food they consume. In the case of the water vole the teeth cease to grow when the animal is adult, calification then aiding the resistance to wear.

The presidential address to the Archæological Section was given by Mr. N. Smedley on "Archæology in Suffolk". Speaking on the early investigators he mentioned the finding of an Acheulean implement by John Frere in 1797 and the scepticism with which the suggestion of man's existence before the present world conditions was received. He traced the development of the beaker pottery forms through the neolithic, bronze and iron ages. Roman times in Suffolk showed a specialized form of kiln with no raised floor during firing. Mr. Smedley had supervised the reconstruction of a kiln of this type to prove the possibility of obtaining the necessary draught and temperature for the baking of clay vessels.

Mr. F. W. Simpson gave the presidential address to the Botanical Section, his subject being "Changes in the Suffolk Flora during the Past 100 Years". He emphasized the need for the conservation of habitats, pointing out that since Henslow's Flora was published in 1860 about 75 natives had become extinct, another 40 will soon be gone and others are in danger of such a fate. This is largely due to suitable habitats being reduced by human development for building purposes. The introduction of aliens may increase the number of species, and for an understanding of the general situation it is important that records of first and last appearances of species should be kept.

An appointment in America prevented Dr. R. G. West from delivering his presidential address to the Geological Section in person, but a recording was available on "Investigating Glacial and Interglacial Geology in East Anglia". Three methods have been used in the determination of the relations of the deposits: tracing the origins of the boulders by the identification of the materials; the study of the orientation of the boulders by the alignment of the long axes in undisturbed deposits; pollen analysis, the size and pattern of the pollen showing the genera and sometimes the species present, so from the vegetational sequence a climatic one could be deduced. Four main glacial periods may be correlated by these methods, the oldest Cromerian, followed in turn by Lowestoft, Gipping and Hunstanton. Implements occurs throughout, the most prolific deposit being the Hoxnian, between the Lowestoft and Gipping glaciations, where Acheulean specimens occur in a deposited brick-earth in conditions at least as warm as at the present time, the pollen grains including pine, birch and oak.

Mr. S. Beaufoy chose for his presidential address to the Zoological Section the subject of "Some East Anglian Butterflies". Illustrating his address with coloured slides of outstanding merit, he commenced by confirming the opinion that a natural boundary appeared to prevent species, including the Speckled Wood and Chequered Skipper butterflies, from occurring in Suffolk although recorded in adjacent Essex. The life-history of the Swallowtail, was described, a British sub-species occurring in Norfolk, the caterpillars feeding on wild carrot and, also, readily taking the leaves of the cultivated variety. The Silverwashed Fritillary is fairly common in woodlands, the eggs being deposited on moss during July and August, the caterpillar's first meal being its egg shell. It then hibernates and nothing more is eaten until the following spring when, by feeding on violet leaves, it completes its larval stage. The White Admiral, quite common in parts of East Anglia, deposits its eggs on honeysuckle, the caterpillars feed for about three weeks and then hibernate throughout the winter. The Purple Emperor was last recorded in 1919, the Large Tortoiseshell has become rare and an attempt to reintroduce the Large Copper has not been entirely successful.

Mr. J. E. Marston, the local secretary responsible for the arrangements of the congress, gave an illustrated talk on "Suffolk Ponds and Pond Animals". Tracing the life history of the mayfly he said that, although the life of the adult did not exceed 24 hr., the nymph takes three years to develop to this stage. The speaker wished for a full investigation into the breeding habits of the freshwater shrimp; preliminary researches at Belstead House have yielded some unexpected results.

Favourable weather conditions enabled the full programme of excursions to be carried out. The archæologists visited Little Wenham Hall, Earl Stonham church and Helmingham Hall. As a prelude to Mr. Smedley's lecture a visit was made to Christchurch Mansion under his direction. The botanists made an excursion to study the early spring flora of the heaths of East Suffolk and the coast, at Woodbridge, Shingle Street, Butley and Chillesford. The geologists were conducted around the quarries at Great Blakenham and Creeting St. Mary to view sections revealing the effect of moving ice-sheets during the Glacial periods.

The general excursion was to Flatford Mill Field Study Centre, where the warden, Mr. F. J. Bingley, conducted the party around the house and grounds, explaining the aims and work of the Field Study Council.

The sixty-sixth annual congress of the Union will be held next year, during May, at Haslemere.

F. J. Epps

ACTINOMYCIN

During March 31–April 1 a conference was held, under the auspices of the New York Academy of Sciences, on "The Actinomycins and Their Importance in the Treatment of Tumours in Animals and Man". The conference consisted of three sessions concerned with: "Microbiological and Chemical Aspects", "Pharmacology and Experimental", and "Clinical". Prof. Selman A. Waksman was the general chairman of the sessions.

Actinomycin was discovered in 1940 in the laboratories of the Soil Microbiology Division of the New Jersey Agricultural Experiment Station, Rutgers University. It was isolated from a culture of an actinomycete, later described as *Streptomyces antibioticus*. Since then, numerous other forms of actinomycin have been isolated throughout the world. The first was designated as A, and the subsequent ones as B, C, D, X, etc. Each of these consists of several chemical entities. Nearly fifty letters, numbers and subscripts have been used to designate the various entities. To clarify the nomenclatural problem, it has been suggested that names be applied to the various preparations only after the chemical constitution of each new form has been elucidated.

The actinomycins are produced by a variety of different species of *Streptomyces*. They represent a group of chromopeptide antibiotics which differ only at one site in the peptide portion of the molecule. The nitrogen source supplied to the medium influences greatly the quantitative and qualitative composition of the actinomycins. The chemical composition of the actinomycins can be controlled during biosynthesis, notably through the addition of sarcosine, pipecolic acid, valine, *iso*leucine, and certain other amino-acids to the medium. The chemistry of the actinomycins was reviewed by Prof. A. W. Johnson, of the University of Nottingham, and Prof. Hans Brockmann, of the University of Göttingen.

All the actinomycins contain the same chromophore group, which has been identified as 2-amino-4 : 6-dimethyl-3-phenoxazinone-1 : 9-dicarboxylic acid. The structural differences among the various actinomycins make for differences in their antimicrobial, cytostatic and toxic properties; but there appears to be limited differences in their therapeutic indices against animal tumours and lymphogranulomatosis. An attempt was therefore made to obtain actinomycin derivatives with better therapeutic indices, by means of chemical alterations in the chromophore or peptide portions of the actinomycins. Structural changes in the actinomycin chromophore may be accomplished if one exchanges the amino-grouping of the chromophore for chlorine, and if the resulting chloro-actinomycin is then made to react with primary or secondary amines, or with other compounds which contain amino or imino groups. Brockmann reported total synthesis of actinomycin C_3, identical in chemical and biological behaviour with the natural preparations.

Among the various actinomycin preparations tested upon animals and in clinical medicine, C (the German preparation) and D (the American preparation) received the greatest attention at the conference. The Sloan–Kettering group reported that fatal intoxication with actinomycin D, following supralethal doses which caused death in less than 24 hr., might possibly be due to extensive damage of the intestinal epithelium allowing entrance of an endotoxin or a toxic polysaccharide into the blood stream. The antibiotic, at the LD_{50} dose, induces extreme hypoplasia in the bone marrow. Neutrophilic granulocytosis is the usual finding; the short survival period is probably insufficient time to reflect the full consequence of destruction of bone marrow. Changes in the lymphoid tissues are presumably direct actions of actinomycin D, since they can be observed in adrenalectomized as well as in normal rats. Actinomycins D and F_1 produce about the same increase in survival time (less than 100 per cent) when tested against a variety of leukæmias. Actinomycin F_1 is active against spontaneous mammary cancer of mice, whereas actinomycin D is without effect. The majority of the 32 actinomycin derivatives tested have little effect against the leukæmias.

A group from the Institute of Microbiology of Rutgers University reported that the antitumour effects of actinomycins II, III and IV have been studied in four ascitic tumour systems. The intraperitoneal therapeutic index of actinomycin II was found to be twice that of actinomycin IV and 4-fold that of actinomycin III in the Gardner lymphosarcoma system. The effective dose chosen for this calculation was the minimal amount producing a 100 per cent increase in survival time. The maximal effect of the actinomycins was attained with a total dose ranging from 1/15 to 1/40 of the LD_{50} dose, when the actinomycins were administered intraperitoneally for three successive days. The group from the Children's Hospital (Boston) reported that the most striking effects on transplanted tumours in mice were produced on the *S*91 melanoma, *P* 1534 lymphatic leukæmia, *DBRF* mammary adenocarcinoma, and the Ridgway osteogenic sarcoma. A synergistic effect with actinomycin D and radiotherapy has been demonstrated in mice bearing the Ridgway osteogenic sarcoma, as well as on normal mouse skin. A variety of heterologous tumours, including human cancers, have been grown in hamsters and afterwards treated successfully with actinomycin D.

The work of the Bayer group in Germany with actinomycin C and other preparations were reported by Dr. C. Hackmann. In tissue-culture studies using HeLa cells, morphological changes of the nucleoli occur which are characteristic of the actinomycins. These changes have not been observed so far with other antitumour agents.

Clinically, when used alone or in conjunction with radiation, actinomycin D has produced objective remission of varying duration in a limited number of cancers. Regression of tumour-size as well as disappearance of metastatic lesions (especially pulmonary) may last for a few weeks to several years (up to five). The tumours which have thus far been found sensitive to actinomycin D are: Wilms's tumour, rhabdomyosarcoma, Ewing's sarcoma, chloriocarcinoma of testis and uterus, lymphomas (Hodgkin's disease and lymphosarcoma), and bronchogenic carcinoma. Of these 'responsive' tumours, the most extensively studied has been Wilms's tumour. The greatest proportion of regressions occurred in this group of patients. With the other tumours considered to be sensitive, a smaller number showed adequate results. Responses in children are more favourable than in adults.

Actinomycin is capable of reactivating, in distribution and amount, the skin and mucous membrane reactions produced by initial irradiation. When used during the course of irradiation, actinomycin can also cause severe reactions. This potentiating effect of actinomycin D must be considered when combination therapy is contemplated. Doses of X-ray and actinomycin D must be adjusted and scrupulous care taken to exclude all normal tissues possible from the radiation beam. Most, if not all, of the patients treated with actinomycin show one or more toxic manifestations, all of which are reversible when the drug is discontinued. The severity of toxicity varies markedly, being only partly dependent upon the dose of drug. Toxicity usually does not become apparent until 2–4 days after the course of actinomycin D is stopped, and may not be maximal before 1–2 weeks have elapsed. Nausea and vomiting, however, occur within several hours after administration.

Actinomycin C has an almost selective cytostatic effect on lymphatic tissue. Its clinical use is limited therefore to Hodgkin's disease and chronic lymphatic leukæmia. In Hodgkin's disease, Begemann reported that remissions occurred in 22 of 54 patients whose disease was far advanced and refractory to other treatment, and in 19 of 38 patients who were responsive to other forms of therapy (in whom actinomycin was used in combination with X-rays and other drugs). Remissions, however, are short-lived. Because actinomycin C does not produce depression of the bone marrow, it is particularly suited for therapeutic trials in patients with aleukæmic forms of Hodgkin's disease or chronic lymphatic leukæmia. Although bone-marrow depression does not occur, actinomycin C also produces gastrointestinal, dermatological, neurological, and soft tissue toxicity including: nausea, vomiting, diarrhœa, loss of feeling of well-being, gingivitis, stomatitis, glossitis, alopecia, polyneuritis, and irritation of veins and thrombophlebitis.

U.S NATIONAL ACADEMY OF SCIENCES

ELECTIONS TO MEMBERSHIP

AT the recent annual meeting of the U.S. National Academy of Sciences, Dr. Lloyd V. Berkner, president of Associated Universities, Inc., in New York City, was elected to a four-year term as treasurer of the Academy. Prof. G. Evelyn Hutchinson, Sterling professor of zoology, Yale University; and Dr. Robley C. Williams, professor of virology and research biophysicist, University of California, were elected members of the Council of the Academy in succession to Dr. Frederick Seitz and Dr. Harry L. Shapiro.

Also at this meeting, thirty-five new members were elected as follows:

Prof. H. L. Anderson, director of the Enrico Fermi Institute for Nuclear Studies;

Dr. A. V. Astin, director of the U.S. National Bureau of Standards since 1952;

Prof. N. Bloembergen, professor of applied physics, Harvard University;

Prof. A. T. Blomquist, professor of organic chemistry, Cornell University;

Prof. H. G. Booker, professor of electrical engineering, Cornell University;

Prof. A. C. Braun, professor of bacteriology, Rockefeller Institute;

Prof. O. Chamberlain, professor of physics, University of California;

Prof. N. R. Davidson, professor of chemistry, California Institute of Technology;

Prof. W. Feller, Higgins professor of mathematics, Princeton University;

Dr. Herbert Friedman, superintendent, Atmosphere and Astrophysics Division, U.S. Naval Research Laboratory.

Dr. R. Galambos, chief of the Department of Neurophysiology, Walter Reed Army Institute of Research;

Prof. M. Gell-Mann, professor of theoretical physics, California Institute of Technology;

Prof. D. R. Griffin, professor of zoology, Harvard University;

Prof. H. S. Gutowsky, professor of physical chemistry, University of Illinois;

Prof. B. Haurwitz, professor of astro-geophysics, University of Colorado;

Prof. H. D. Hedberg, professor of geology, Princeton University;

Prof. K. F. Herzfeld, professor of physics and head of department, Catholic University of America, Washington, D.C.;

Prof. C. I. Hovland, Sterling professor of psychology, Yale University;

Dr. R. J. Huebner, chief of the Laboratory of Infectious Diseases, U.S. National Institute of Allergy and Infectious Diseases;

Dr. A. B. Kinzel, vice-president in charge of research, Union Carbide and Carbon Corporation;

Prof. S. E. Luria, professor of microbiology, and chairman, Microbiology Committee, Massachusetts Institute of Technology;

Prof. D. Mazia, professor of zoology, University of California at Berkeley;

Prof. S. Moore, professor of biochemistry, Rockefeller Institute;

Prof. T. T. Puck, professor of biophysics and head of department, University of Colorado Medical School;

Prof. R. W. Sperry, Hixon professor of psychobiology, California Institute of Technology;

Prof. W. H. Stein, professor of biochemistry, Rockefeller Institute;

Prof. W. S. Stone, professor of zoology and director of gene research, University of Texas;

Prof. G. J. Stork, professor of chemistry, Columbia University;

Dr. R. N. Tousey, head of the Rocket Spectroscopy Branch, Atmosphere and Astrophysics Division, U.S. Naval Research Laboratory;

Prof. J. B. Wiesner, director, Research Laboratory of Electronics, Massachusetts Institute of Technology;

Prof. G. R. Willey, Bowditch professor of Central American and Mexican archæology, Harvard University;

Prof. C. M. Williams, professor and chairman, Department of Biology, Harvard University;

Dr. O. C. Wilson, astronomer, Mount Wilson and Palomar Observatories;

Prof. C. N. Woolsey, Charles Sumner Slichter research professor of neurophysiology, University of Wisconsin;

Prof. A. Zygmund, professor of mathematics, University of Chicago.

'EIDOPHOR' TELEVISION TECHNIQUE

A DEMONSTRATION of the 'Eidophor' system of projection television was given during the week beginning May 2 by Messrs. Ciba Clayton, Ltd., at Belle Vue, Manchester. A studio was set up in the technical service laboratories, and the programme was transmitted 'live' a distance of 1½ miles to Belle Vue by micro-wave link. The aim was to demonstrate the use of the new system to enable lecture demonstrations to be given to very large audiences. The organizers are to be congratulated; it was a most impressive demonstration.

The essential feature of the 'Eidophor' system is a special cathode-ray tube which modulates a beam of light derived from a high-power xenon arc. In principle, therefore, the limit to the size of screen used and the brightness of the picture is set only by the light output of the lamp, and not, as in most other systems, by the characteristics of the phosphor of a projection tube. A screen of up to about 800 sq. ft. may be used for black-and-white projection with the system in its present state of development; there is necessarily some diminution in brightness in colour television, but even then screens up to about 200 sq. ft. may be used.

It is not proposed to describe in detail the technical aspects of the system except to comment first on its extreme ingenuity, and secondly, on the skill and patience which must obviously have been used in its perfection. The 'modulator' is a mirror over which a thin film of oil is continuously re-formed. The thickness of the oil film is controlled by the electric charge pattern on its surface, and this in turn is controlled by the cathode-ray beam. The variations in thickness are used to control the intensity of the light from the source. The idea is simple in conception, but there are considerable technical difficulties that have had to be surmounted. The 'Eidophor' projector may be fed by signals from a broadcasting network or from a closed-circuit link. The large amount of light available makes possible the use of a simple frame-sequential colour system, and the demonstration at Belle Vue was of this kind. An ordinary television camera is used to provide the signals, but a three-colour rotating filter is mounted in front of the lens. A similar rotating filter—synchronized by special signals—rotates in front of the light source in the projector. The rate of frame repetition is 75 per sec., so that a complete set of three coloured images is transmitted in the normal frame-time of one-twenty-fifth of a second. The colour quality—though not perfect—was quite adequate for technical demonstrations.

A series of short lectures was given, starting with a technical description of the 'Eidophor' by Arthur Garratt and followed by three or four demonstration lectures of dyeing processes and techniques, including paper chromatography. After the lectures the audience was invited to ask questions, and these were answered from the studio over the television link. It was this last feature that demonstrated most clearly the fascinating possibilities of large-screen television. As research becomes more and more concerned with complex apparatus, so lectures with demonstrations become more and more difficult except for very small audiences. A really good colour projector would make it possible for a large audience to see and hear lectures with the same comfort as a single person ; it is possible, of course, to use close-up techniques and even to transmit the images from microscopes and other optical instruments. The 'Eidophor' system brings this idea into the realms of possibility, though as yet, of course, the number of projectors available is small and their cost relatively high.

The demonstration at Belle Vue involved the transportation of two large van-loads of equipment and a team of Swiss experts to Britain, and clearly involved a great deal of work for the organizers ; the result certainly justified the effort. C. A. TAYLOR

INSECTS AND LENGTH OF DAY

STANLEY D. BECK, of the University of Wisconsin, has studied the effect of temperature on the hibernation of the European corn borer, a species of moth that passes the winter not as an egg but as a mature larva (*Sci. American*, 202, February 1960). The corn borer is a long-day insect. Generation after generation can be reared in the laboratory if the cultures are maintained under any of three different conditions : 16 hr. of light a day, continuous darkness or continuous light. In the absence of suitable photoperiod—that is, in continuous light or darkness—temperature has only a slight effect on the incidence of hibernation. Similarly, if a batch of borer larvæ are exposed to short photoperiods of 10·5–13·5 hr. of light a day, they will go into diapause regardless of the temperature at which they are reared. At photoperiods of 8–10 hr. and 14–15·5 hr., however, temperature exerts a powerful influence on the incidence of hibernation : high temperatures tend to prevent it and low temperatures to increase it.

This sensitivity to temperature is important in the life-cycle of the borer. It explains why two generations of them are produced each season in southern corn-growing areas, while only one generation is produced in northern areas. If photoperiod were the only factor governing their reproduction the opposite would be expected, because on any given day in summer the period of daylight is shorter in the south than in the north. The higher temperatures of the earlier southern growing-season, however, more than compensate for the shorter days.

In contrast to the silkworm and the aphid, which are sensitive to photoperiod only in the early stages of development, the borer remains responsive for a longer time. Present evidence indicates that it becomes sensitive in the later stages of larval development or is uniformly sensitive throughout the entire period of growth.

Photoperiod affects members of the growing generation of corn borers but not their progeny. There is no carry-over to the next generation as in the silkworm and the aphid. In the corn borer the earliest detectable symptom of impending diapause is a failure of the reproductive organs to develop. At a stage when the sex cells are rapidly maturing in borers reared under long photoperiod, these cells have ceased to develop in larvæ reared under short photoperiods. The short-photoperiod borers still feed and grow rapidly, but the growth of their reproductive organs is arrested. Similar gonadal arrest has been observed in a number of other species of hibernating insects, including such diverse types as boll weevils and Colorado potato beetles.

In insects, as in higher animals, growth and gonadal development are controlled by hormones. The insect growth-hormone has been identified as ecdysone, which is produced by glands in the insect's thoracic tissue. Insects in diapause contain no detectable amounts of ecdysone, but if they are injected with it, they soon resume normal development. It appears that the change in photoperiod inhibits the production of ecdysone. How this inhibition is brought about is not known. Perhaps a diapause hormone is responsible, especially in forms like the aphid and silkworm. If this is so, the insects must be sensitive to the hormone only at certain times during their lives.

Another unresolved issue is the nature of the timing mechanism that enables an insect to distinguish between a 16-hr. photoperiod and one of, say, 12 or 13 hr. A light receptor is required, because the insect must discriminate between light and dark to respond to photoperiod at all. Apparently the eyes are not involved, and the shielding of different parts of the insect's body has not located any other organ or nerve ending that is specially sensitive to photoperiod. All parts of the body seem equally sensitive. It now seems likely that the receptors are either numerous cells scattered over the body surface, or that they are the cells of the integument itself.

The quantity of light involved has little to do with the photoperiod reaction, so long as the intensity is greater than a very low threshold value—usually less than 1 ft.-candle. This suggests that no photochemical reaction is involved; for the rate of most photochemical processes increases with greater light intensity. It is possible that a small-scale photochemical reaction may act as a trigger; in that case the most important cause of the photoperiod response would not be the presence or absence of light, but the stimulus produced by the change from light to dark, and vice versa. Each 24-hr. day involves one change of light to dark, and one change from dark to light, but these changes can provide no more than a series of stimuli that start a biological switch. Because different day-lengths induce different responses, the switch presumably activates the biological clock. The clock measures the changing interval between stimuli and regulates the physiology of the insect accordingly.

The existence of such a clock can easily be demonstrated in the European corn borer. When a batch of borers are reared under photoperiods of 12 hr. of light and 12 hr. of darkness, all of them go into hibernation. The ratio of light to dark in this case is one to one. When an artificial 12-hr. day is created with a one to one ratio of six hours of light and six hours of darkness, none of the borers hibernates. A 'day' of at least eight hours of darkness is apparently required to induce hibernation.

PAPER CHROMATOGRAPHY: MULTIPLE SPOT FORMATION BY PURE SUBSTANCES

By Dr. A. H. BECKETT, M. A. BEAVEN and Dr. ANN E. ROBINSON
School of Pharmacy, Chelsea College of Science and Technology, London

PURE pharmacologically active amines give more than one spot on paper chromatograms in the presence of certain acids (unpublished observations). Because this phenomenon lacked rationale and has important implications in relation to metabolic studies, we have examined the paper chromatographic behaviour of some amines and amine salts in detail. Using acidic (and neutral) solvent systems, we have shown that double amine spot formation on paper chromatograms is dependent on three major factors: the relative R_F values of the individual acids and bases of the salt, the relative concentrations of the acids and bases and the relative dissociation constants of the added acid and that present in the solvent system.

The chromatographic behaviour of monoacidic amines in a water-saturated *n*-butanol–acetic acid solvent system is summarized as follows: a single amine spot, having an R_F value similar to that of the free base, is obtained when weak acid salts (for example, propionates, mandelates, citrates) of many amines (for example, adrenalin, codeine, amphetamine, propylamine) are chromatographed. With an organic acid salt, in which the organic acid has a low *pKa* (less than 1) and a high R_F value (for example, trichloracetic acid *pKa* 0·65, R_F 0·90), two amine spots are obtained unless the amine and acid have similar R_F values (for example, chlorpromazine trichloracetate, R_F of the base 0·92) or the amine is very insoluble in water (for example, analgesics based on the piperidine structure[1]). Of the two amine spots, one has an R_F value corresponding to that of the free base while the other is associated with the acid spot. The position of the latter amine spot is dependent upon the R_F value of the acid. Thus, the separation of the amine into two spots and their relative positions is dependent on the relative R_F values of the components. The results for various amine trichloracetates are represented diagrammatically in Fig. 1.

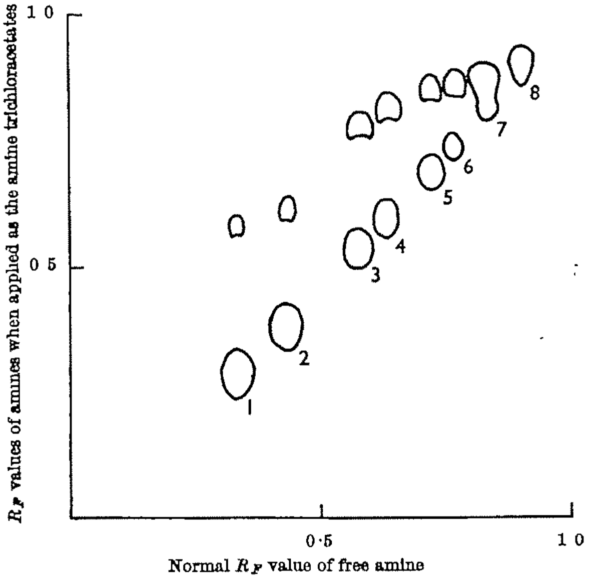

Fig. 1. Chromatograms of amine trichloracetates (about 20 μgm.) run in *n*-butanol–acetic acid–water (4 : 1 : 5) on Whatman No. 1 paper. Tailing is not shown. 1, noradrenalin; 2, adrenalin, 3, propylamine and codeine; 4, tyramine, 5, β-phenylethylamine; 6, ephedrine and amphetamine; 7, papaverine; 8, chlorpromazine

With salts showing double amine spot formation, chromatography of the salt in the presence of an excess of the acid results in a greater proportion of the base becoming located in the spot associated with the acid. A single amine spot is obtained if a sufficient quantity of acid is used, the amount of acid required being dependent on the difference between the R_F values of the individual components. However, amines of low R_F value (for example, noradrenalin and adrenalin, R_F 0·34 and 0·42) always formed two amine spots in the presence of trichloracetic acid even using a twenty molar excess of the latter. Increasing the acid concentration also results in the R_F value of the amine spot associated with the acid approaching that of the free acid, whereas the R_F value of the second amine spot (if still present) is analogous to that of the free base.

Tailing between the two base spots was most marked where the R_F values of the components were widely separated and with the salts of weaker acids. It became less obvious if smaller amounts of the amines were applied to the paper when discrete spots may be obtained, that is, the detection of tailing is a function of reagent sensitivity.

Salts of bases and organic acids in which the R_F value of the free base is greater than that of the free acid yield a single amine spot associated with the acid, unless the R_F values of the components are widely separated (for example, N-phenethyl 3-methyl 4-(*o*-tolyl)4-acetoxypiperidine trichloracetate R_F of the base is 1·0) when complete acid/base separation occurs. Examples are ephedrine maleate (R_F 0·77; ephedrine, R_F 0·76; maleic acid, R_F 0·71) and ephedrine picrate (R_F 0·88; picric acid, R_F 0·74). In contrast, propylamine maleate yields two amine spots (R_F 0·56 and 0·67 with tailing in between; propylamine, R_F 0·59).

Although double amine spot formation depends partly upon the relative dissociation constants of the acids present in the salts and in the solvent, the proximity of the R_F values of the acids and bases is the governing factor with the salts of weaker organic acids (*pKa* values of 1–3). If the difference between the R_F values of the acids and bases is small, two amine spots are obtained (for example, propylamine, isoprenaline and phenylethylamine dichloracetates, R_F values of the bases are 0·59, 0·60 and 0·73, respectively, and the R_F value of dichloracetic acid is 0·83. Complete separation of the base from the acid, with consequent single amine spot formation, occurs if the R_F values of the acid and base are widely separated (for example, noradrenalin and adrenalin dichloracetates).

The shapes and R_F values of amine spots are modified by inorganic acids such as sulphuric and hydrochloric acids (R_F 0·39 and 0·38, respectively). Elongated amine spots are produced by the sulphates and hydrochlorides of noradrenalin and adrenalin; the acid spots overlap those of the bases. Using excess of sulphuric acid but not hydrochloric acid both these substances formed spanner-shaped amine spots; the acid was located in the cup and also overlapping the base of the amine spot. Amines of intermediate R_F values (for example, propylamine) formed inverted crescent-shaped spots at the base of the main acid spot in the presence of an excess of a mineral acid. Complete acid/amine separation occurred with the sulphates and hydrochlorides of phenylethylamine and atropine (R_F 0·78) and normal amine spots were obtained. In contrast, phenylethylamine and ephedrine dissolved in an excess of trichloracetic acid produced crescent-shaped amine spots at the apices of the acid spots while, under the same conditions, codeine (R_F 0·57) and isoprenaline appeared as half-moon-shaped spots in the upper area of the acid spots.

Ghost spots[2] were observed with all phenolic amines in the presence of excess of any of the stronger acids.

In a neutral solvent system (water-saturated *n*-butanol) *all* except the more volatile acids profoundly affected the R_F values of the amines; acid/base separation of the salts occurred, but to a lesser extent than in the acidic solvent. If the R_F values of the base and acid were close (and the R_F value of the latter was greater than that of the former) one amine spot, associated with acid, was detected having an R_F value similar to that of the acid. With a greater difference between the R_F values of the individual components two amine spots were produced, whereas, with widely varying R_F values, complete acid/base separation occurred and a single amine spot was observed.

Using a basic solvent system (water-saturated *n*-butanol–ammonia) the R_F values of the amines, as expected, remained unchanged in the presence of any of the acids tested.

Multiple spot formation is not necessarily indicative of the presence of different substances. The present work re-emphasizes that reference substances and unidentified materials must be chromatographed under identical conditions, if valid deductions are to be drawn. This is particularly important with amines in biological extracts which may also contain certain organic acids, or to which trichloracetic acid has been added. Even when free bases are liberated with alkali and extracted and chromatographed, the presence of trace amounts of acid or salts carried over during extraction can cause multiple spot formation from single substances. Similar remarks also apply to the chromatographic examination of acids in basic solvents.

Thus the chromatographic investigation of the metabolism of basic drugs may readily yield more spots than there are metabolites if strongly acidic compounds are also products of metabolism. The addition of bases (for example, ephedrine) to urine, for example, may yield more than one base spot in neutral running solvents because of the presence of acids.

This and related work with other systems will be described in detail elsewhere.

DISPROPORTIONATION AND DIMERIZATION OF THE BENZYLOXYL FREE RADICAL IN SOLUTION

By DR. J. B. de SOUSA
University of Malaya in Kuala Lumpur

AND

S. K. HO
University of Hong Kong

ALTHOUGH the mutually competitive processes of disproportionation (1) and dimerization (2) of alkoxyl radicals:

$$2R\text{CH}_2\text{O}\cdot \longrightarrow R\text{CHO} + R\text{CH}_2\text{OH} \qquad (1)$$

$$2R\text{CH}_2\text{O} \longrightarrow R\text{CH}_2\text{O—OCH}_2R \qquad (2)$$

have been much discussed from the thermochemical point of view[1,2] actual evidence in support of (1) and (2) is somewhat scanty.

Disproportionation for various alkoxyl radicals is regarded as a highly exothermic process. Gray[1] has assigned enthalpies in excess of 80 k. cal. mole^{-1}, and activation energies are expected to be very small or zero. Reaction (1) has been postulated to explain certain features of the decomposition of diethyl peroxide in presence of ethyl nitrite and nitric oxide[3]. The presence of benzaldehyde in the decompositions of benzyl nitrite and dibenzyl hyponitrite in solution has been considered by Gray[1] as evidence for disproportionation. However, this must await a kinetic study in order to ascertain the importance of induced reaction which may also yield benzaldehyde by the following reactions :

$$\left.\begin{array}{ccc} R\cdot + \mathrm{PhCH_2O{-}N = N{-}OCH_2Ph} & & R\mathrm{H} + \mathrm{PhCHO{-}N = N{-}OCH_2Ph} \\ \text{or} & \longrightarrow & \text{or} \\ \mathrm{PhCH_2O{-}N = O} & & \mathrm{Ph{-}\dot{C}HO{-}N = O} \end{array}\right\} \quad (3)$$

$$\left.\begin{array}{ccc} \mathrm{Ph\dot{C}HO{-}N = N{-}OCH_2Ph} & \longrightarrow & \mathrm{PhCHO + N_2 + PhCH_2O\cdot} \\ \mathrm{Ph\dot{C}HO{-}N = O} & \longrightarrow & \mathrm{PhCHO + NO} \end{array}\right\} \quad (4)$$

Wijnen[4] has considered evidence for disproportionation of methoxyl radicals in the photolysis of methyl $- d_3$ acetate at 30° and 90°.

At these comparatively low temperatures no evidence to support reaction (2) was available. Evidence for dimerization in solution is quoted for the 2-phenyl propan-2-oxyl radical by Gray[1] and Walling[5]:

$$2\mathrm{Ph{-}C(Me)_2 - O\cdot} \longrightarrow \mathrm{(Ph{-}CMe_2{-}O)_2} \qquad (5)$$

The work actually referred to is that of Kharasch *et al.*[6], who themselves doubt whether the peroxide is formed by dimerization. This case should be favourable to dimerization as competition from disproportionation is absent. Dimerization should be exothermic to the extent of 35–40 k. cal. mole^{-1}. The kinetics of thermal decomposition of dibenzyl hyponitrite in solution has been studied by us. The decomposition is first-order for at least 75 per cent of complete reaction. Induced reaction is, however, evident as the rates are lowered by presence of inhibitors such as quinones, and vinyl monomers. At sufficiently high concentration of *p*-benzoquinone the rate becomes independent of quinone concentration and the decomposition is first-order throughout the range of accurate observation (more than 90 per cent decomposition). The activation energy for this first-order decomposition is 24·9 ± 0·25 k. cal. mole^{-1}. This low value suggests a simultaneous rupture of both O—N bonds resulting in the elimination of a nitrogen molecule and the formation of two benzyloxyl radicals in a 'cage'[7]. Dibenzyl hyponitrite is known to polymerize methyl methacrylate[8]. We also have evidence to support radical intermediates in the decomposition of dibenzyl hyponitrite in solution :

$$\mathrm{PhCH_2O{-}N = N{-}OCH_2Ph} \longrightarrow 2\mathrm{PhCH_2O\cdot} + \mathrm{N_2} \quad (6)$$

Table 1. PERCENTAGE YIELD OF BENZALDEHYDE IN THE DECOMPOSITION OF DIBENZYL HYPONITRITE IN *cyclo*HEXANE AT 40° C.

Concentration of solution (mole/l.)	Per cent C_6H_5CHO
0 1000	65 34
0 0500	65 58
0 0100	57 38
0·00748	55 80
0·00500	53 15

0·00301	53 95
0·00198	53 02
0 00149	51 29
0 00100	50·55
0 000500	50·29
0 000103	50 29

The products isolated from solutions were benzaldehyde (as 2 : 4-dinitrophenylhydrazone) and benzyl alcohol (as 3 : 5-dinitrobenzoate) in high percentage yields. In *cyclo*hexane solutions the benzaldehyde is readily detectable by its maxima at 240, 276 and 285·5 mμ. At 285 5 mμ benzaldehyde absorbs strongly (ε = 1,000) whereas benzyl alcohol absorption is negligible (ε = 2) and this maximum was used for quantitative analyses for benzaldehyde. As the induced reaction is a second-order reaction it should be less important at high dilutions whereas the 'cage' reactions are independent of concentration. A study of benzaldehyde yield for various concentrations is shown in Table 1.

The yield drops from 65 per cent at 0·1 *M* to 50 per cent at 0 001 *M* and remains stationary thereafter to the extreme dilution studied of 0·0001 *M*. The high and constant yield of benzaldehyde at high dilutions strongly supports the formation of benzaldehyde solely by a 'cage' disproportionation. A pair of benzyloxyl radicals formed in a 'cage' by decomposition of a molecule of dibenzyl hyponitrite may undergo disproportionation, dimerization or separate by diffusion. Benzaldehyde may thus be formed through a reversible fission of dibenzyl peroxide if any is formed. The half-life of dibenzyl hyponitrite at 35° in *cyclo*hexane is 2·46 hr.

Dibenzyl peroxide does not appear to be known ; it should have approximately the same half-life as comparable peroxides. In solution di-α-cumyl peroxide would have a half-life of 1·26 × 10^6 hr. at 35° (by extrapolation)[9]. Thus at 35° it would appear that benzaldehyde should be formed directly from the disproportionation of benzyloxyl radicals generated by the parent hyponitrite.

A study of the rate of appearance of benzaldehyde in *cyclo*hexane solutions using the 285 5 mμ maximum was attempted. The optical density increased rapidly though the kinetics were not strictly first-order. This may be due to the fact that dibenzyl hyponitrite has a small but finite absorption at 285 5 mμ (ε = 20). Half the final yield of benzaldehyde is formed in 2·75 hr. This compares with 2·46 hr. for the half-life of dibenzyl hyponitrite in *cyclo*hexane at 35°. After several half-lives at 35° the yield of benzaldehyde remains constant (Table 2).

Thus the yield after 96 and 151 hr. at 35° is the same (49 per cent), indicating that dibenzyl peroxide if present does not appear to give benzaldehyde in this

Table 2. BENZALDEHYDE ANALYSES (IN DUPLICATE) FOR 0 00076 *M* SOLUTIONS OF DIBENZYL HYPONITRITE IN *cyclo*HEXANE AFTER DECOMPOSITION

	Optical density			Per cent C_6H_5CHO
	Sample *A*	Sample *B*	Average	
96 hr. at 35°	0 378	0·374	0 376	49 01
96 hr. at 35° + 65 hr at 35°	0 379	0 373	0 376	49 01
96 hr. at 35° + 65 hr. at 100°	0·419	0 420	0 420	54 74

period of time. However, subjecting solutions which had undergone decomposition for 96 hr. at 35° to a further 65 hr. at 100° C. (where the calculated half-life of dibenzyl peroxide is 55 hr.) increased the yield of benzaldehyde by 5 per cent. The reverse of reaction (2) followed by disproportionation (1) is indicated.

It appears that benzyloxyl radicals undergo disproportionation and dimerization in a 'cage', and their relative rates may be thus studied. Experiments are being undertaken aimed at isolation of dibenzyl peroxide as well as detection, product and kinetic studies by gas chromatography and infra-red spectroscopy.

One of us (S. K. H.) is grateful to the Education Department, Hong Kong, for permission to participate in this work.

SYNTHETIC POLYELECTROLYTES AS TUMOUR INHIBITORS

By Dr. WILLIAM REGELSON, STEPHAN KUHAR and MARVIN TUNIS

Roswell Park Memorial Institute, Buffalo, New York

AND

JOSEPH FIELDS, JOHN JOHNSON and EARL GLUESENKAMP

Monsanto Chemical Company, Dayton, Ohio

ANIONIC polysulphonates and polyphosphates of either natural or synthetic origin have been shown to be potent inhibitors of transplanted tumours in mice[1–4]. This inhibition of tumour growth may conceivably be a function of the density and distribution of ionic charges within the polyelectrolyte molecule. To test this hypothesis, the tumour-inhibiting properties of synthetic polymers of varied charge-densities were studied.

Two classes of synthetic polymers were chosen: polycarboxylates derived from ethylene/maleic anhydride copolymers and those derived from polyacrylic acid. (For convenience, in the ethylene/maleic anhydride copolymer (EMA) series, hydrolysed (free carboxyl) form is abbreviated HEMA and the ammoniated (amide-acid form) is noted as AEMA.) The charge-density and solution configuration of these compounds were varied over a wide range, by proper choice of substituents on the backbone of the molecule and by substitutions on the carboxyl groups. In the ethylene/maleic anhydride copolymers, functional groups are attached to immediately adjacent carbon atoms of the ethylene backbone, whereas in the polyacrylic copolymers functional groups are attached to backbone carbon atoms separated by a methylene unit. Because of this difference, the two classes of polymers differ in ion strengths as well as charge distribution. For each class of polymer two different series were studied: the free dicarboxylic acids and the carboxamide–carboxyl types, each in several molecular-weight ranges. The effect of these compounds on the growth of transplanted tumours in mice is reported in this article.

In most experiments, sarcoma 180 was the tumour used. Additional experiments were conducted with Krebs 2 carcinoma, leukæmia *L*-1210 and carcinoma 755, maintained and tested in appropriate host strains[5].

Sarcoma 180, Krebs 2 carcinoma or leukæmia *L*-1210 ascites tumour cells, grown for 5–7 days in the donor mouse, were injected subcutaneously into the flank of test animals as a 0·2-ml. suspension of approximately 5,000,000 cells. Non-necrotic solid sarcoma 180 or carcinoma 755 tumour, 6–14 days old when transplanted, was placed by trocar into the flank of the appropriate host as a fragment approximately 2 mm. in diameter. Solid tumour, derived from either solid tumour or subcutaneously placed ascites cells, responded in essentially the same manner to HEMA and AEMA. In all experiments, mice were uniform with respect to sex, age and weight. They were allocated at random 3–5 to a cage. Preliminary experiments in which several levels of the drugs were tested in groups of Swiss mice served to establish the minimal lethal dose of drug when given in six

INHIBITION OF SUBCUTANEOUS SARCOMA 180

daily doses. The final experimental groups consisted of a minimum of 10 mice.

Solutions of the compounds to be tested were prepared in isotonic saline and stored in the cold. If necessary, *p*H was adjusted to approximately 7 by titration with dilute sodium hydroxide.

Treatment consisted of a single daily intraperitoneal injection of 0·5 ml. of drug solution, beginning 24 hr. after tumour inoculation. Injections were given for 6 days and animals killed the eighth day after tumour inoculation. The same method was followed with carcinoma 755 except that the tumour was permitted to grow for 7 days prior to start of treatment. Each tumour was removed by dissection, weighed and compared with the tumour-weight of saline-treated control animals.

Experiments in which more than one-third of the treated animals died were not considered valid. Using this criterion of validity, consistent inhibition of sarcoma 180 from 50 to 83 per cent was noted in 41 consecutive experiments with AEMA of different molecular weights. In 19 of these experiments, no animals died. Thus, tumour inhibition is not necessarily a manifestation of non-specific toxicity. For the remaining 33 compounds, single experiments are presented. In 23 of these experiments, inhibition of sarcoma 180 tumour growth of 50 per cent or more occurred. Other experiments at different dose-levels with each of the 33 compounds confirm the general order of tumour inhibitory activity, usually with excessive toxicity when the dose was raised.

Body-weights were recorded at the beginning and end of each experiment. For all experiments, total gain in body-weight of the control mice averaged 3·9 gm. and that for the treated mice 1·9 gm. Loss of weight was found in only 8 out of 64 experiments where the inhibition of sarcoma 180 was 50 per cent or greater, and in only 3 of these experiments did the losses exceed 10 per cent of the pre-treatment weight.

Survival-time in mice bearing ascites tumour was determined after intraperitoneal inoculation of a uniform suspension containing approximately 2,000,000 ascites tumour cells. 24 hr. after tumour inoculation, AEMA or HEMA was given for six consecutive days either intraperitoneally or subcutaneously. Survival-time of these mice was contrasted with control mice treated in similar fashion with saline.

AEMA (mol. wt., 2–3,000 and 20–30,000) given intraperitoneally to mice with Ehrlich ascites tumour clone 2 or leukæmia *L*-1210 ascites and AEMA and HEMA (mol. wt., 20–30,000) given subcutaneously to mice with leukæmia *L*-1210 ascites and Krebs 2 carcinoma ascites did not increase survival-times.

Results in Tables 1 and 2 are presented as the average per cent inhibition of sarcoma 180 determined at dose-levels which range from just less than the minimal lethal dose to a dose which kills no more than one-third of the animals.

Table 1 includes the following maleic anhydride copolymers: the dicarboxylic acid–HEMA, the ammonium salt of AEMA, the amide-acid form of AEMA, the EMA diamide and hydrolysed and amidated propylene and *iso*butylene maleic anhydride. Molecular weights ranged in five groups from approximately 2,000 to 120,000 as estimated from measurements of solution viscosity. Where possible, each compound was tested for inhibitory activity in each of the five weight ranges.

It appears that at least one ionizable carboxyl group is required for the polymers to manifest significant tumour inhibition. The diamide of EMA showed a much lower order of both inhibitory activity and toxicity than HEMA or AEMA. Lethality of the dicarboxylic acid HEMA increased as the molecular weight increased up to 80–100,000. The dicarboxylic acid propylene and *iso*butylene copolymers tested were more toxic, and less active as tumour inhibitors against sarcoma 180 than the corresponding half-amide acid compounds.

Analogous results for polyacrylic acid, polymethacrylic acid, and polyacrylamide are presented in Table 2. In this series, also, the completely amidated product was not significantly effective as a tumour inhibitor and was much less toxic than carboxyl-containing compounds of similar molecular weight. In general, tumour inhibition by polymers of this series was similar to that of corresponding polymers of the series shown in Table 1. Based on the results obtained, the difference between the two series in position of carboxyl groups on the ethylene backbone does not alter greatly the tumour-inhibiting property of the compound.

Fig. 1 presents a comparison of the inhibiting action of low molecular weight (2–3,000) HEMA and AEMA against several tumours. At equivalent doses, monocarboxylic AEMA copolymer was effective against sarcoma 180, leukæmia *L*-1210, Krebs 2 carcinoma and carcinoma 755. Dicarboxylic HEMA

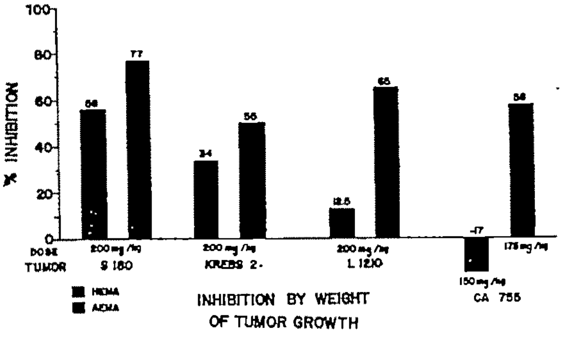

Fig. 1. Comparison of HEMA and AEMA 2–3,000 mol. wt. against a variety of transplanted tumours

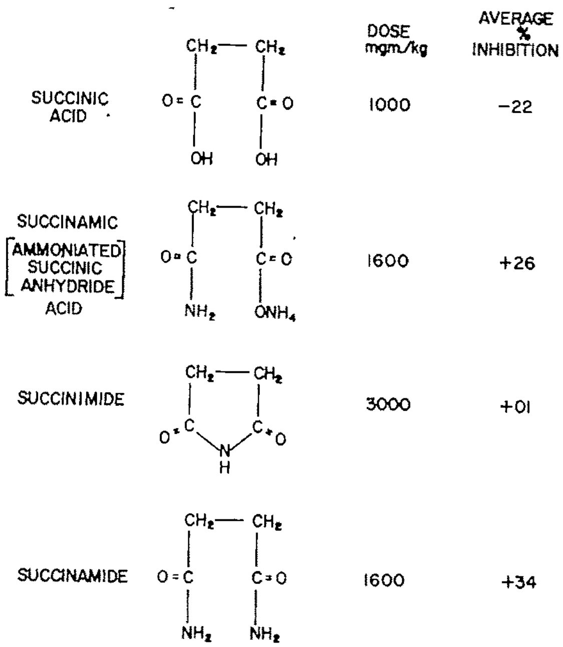

Fig. 2. Inhibition of sarcoma 180 by monomeric fragments of the ethylene/maleic anhydride series

copolymer inhibited only sarcoma 180. This same pattern of inhibition was observed for AEMA and HEMA in molecular weight ranges of 20–30,000 and 60–70,000. AEMA thus showed a broader spectrum of tumour inhibition than HEMA and is the more potent inhibitor of sarcoma 180 at equitoxic doses. (A comparative study with analogous derivatives in the acrylic acid series is being completed.)

The corresponding monomeric fragments of HEMA and AEMA such as succinic acid, succinamic acid, succinimide and succinamide, administered at levels of 1,000–3,000 mgm./kgm., did not show significant inhibitory activity against sarcoma 180 (Fig. 2). These results indicate the necessity for the polymeric structure in producing the observed tumour inhibition.

Tumour inhibition for the two polymer series reported (completely carboxylated and carboxyl–carboxamide types) was strongly dependent on carboxyl substitution, which varied molecular configuration in solution. Within each series, charge-density is one factor which may govern tumour-inhibiting effectiveness and toxicity.

Optimum activity was obtained in the series where carboxamide and ionizable carboxyl groups were interdispersed on the polymer backbone. When all carboxyl groups are converted to carboxamides, significant tumour inhibition was lost. In addition, proper carboxamide–carboxyl balance broadens the scope of activity against a variety of transplanted tumours. Within this series, amide-acids of either ethylene, propylene or *iso*butylene maleic anhydride copolymers exhibited equivalent tumour inhibitory activity at equitoxic dose-levels.

For the completely carboxylated polymers those of weaker degree of ionization (hydrolysed propylene and *iso*butylene maleic anhydride copolymers) were, in general, less active than those of higher charge-density (HEMA, polyacrylic and polymethacrylic acids).

The results of our studies support the hypothesis that tumour inhibition by polyelectrolytes may be a function of charge-density and distribution on the polyelectrolyte molecule. The inactivity of the monomeric fragments tested indicates the necessity for the polymeric structure.

Synthetic polyelectrolytes not only inhibit transplanted tumours but also certain vital enzymes such as ribonuclease and deoxyribonuclease[3,5,6]. The exact mechanism for these effects is not known. The variation which is possible in the physico-chemical characteristics of synthetic polyelectrolytes permits us empirically to define certain properties contributing to tumour inhibition. Predictable reactions between synthetic polyelectrolytes and selected biological systems may eventually be possible by consideration of physico-chemical characteristics of the synthetic and the naturally occurring polyelectrolytes.

This investigation was supported by research grants, *CY*-3887, from the National Cancer Institute, National Institutes of Health, Public Health Service, and the Monsanto Chemical Company.

EFFECT OF OXYGEN AND NITRIC OXIDE ON THE RADIOSENSITIVITY OF HUMAN CELLS IN TISSUE CULTURE

By Dr. D. L. DEWEY

British Empire Cancer Campaign Research Unit in Radiobiology, Mount Vernon Hospital, Northwood, Middlesex

THE sensitivity of cells to radiation can be measured by several different criteria. From the point of view of radiotherapy of cancer, the relevant criterion is a loss of reproductive integrity, that is, the loss of the ability of the cell or its descendants to go on multiplying indefinitely. The work of Puck and his collaborators has shown that it is feasible to measure this form of radiation damage to human cells in tissue culture by observing the fraction of cells that survived, in that they were able to go on dividing and growing to form a visible colony. The radiation procedure used by Puck and Marcus[1] had the disadvantage of an uncertainty in dose, due to the close proximity of the cells to a glass surface[2]. This article reports the results obtained by an alteration of procedure that eliminates the glass surface, and at the same time permits an accurate control of the oxygen tension in the surrounding medium.

The cells used in this work were from human liver, obtained in tissue culture by Westwood[3] and kindly supplied to me by Dr. F. Sheffield. They were grown in closed bottles containing Earle's salt solution, lactalbumin hydrolysate, tryptic meat broth, serum, glucose, antibiotics and bicarbonate—the mixture having been pre-gassed with carbon dioxide. Before irradiation they were removed from the glass surface by incubating with 0·5 m*M* ethylene-diamine-tetraacetic-acid disodium salt for 15 min., then pipetted rapidly to break up clumps. One fraction of the suspension was used for microscopical examination for total cell-count and for a check against clumping. Other fractions were added immediately to phosphate-buffered media in which the bicarbonate had been omitted and replaced by 8 per cent by volume of buffer at *p*H 7·4, made by adding 4 volumes of 0·154 *M* disodium hydrogen phosphate to 1 volume of 0·154 *M* sodium dihydrogen phosphate.

The cells were irradiated in suspension in phosphate buffer in a 'Perspex' ('Lucite') vessel. The solution was bubbled with the gas under test as fast as foaming would permit, for at least 5 min. before, and during irradiation. The radiation used was from a Siemens 'Metalix' X-ray tube operated at 200-kV. constant potential, 8 m.amp., and filtered by 0·5 copper + 0·5 mm. aluminium. The cells were irradiated at room temperature, at a dose-rate of about 600 r./min. 0·1 ml. samples of cell suspension were withdrawn from the vessel before and after irradiation, diluted as necessary, and aliquots placed in closed bottles containing bicarbonate medium, carbon dioxide and an actively metabolizing X-rayed 'feeder layer'. Colonies were counted after 10 days incubation at 37° by scanning the bottle under the low-power objective of a microscope. A ruled grid was placed over the surface of the bottle during counting to ensure that the surface was scanned once, and only once.

The effect of X-rays on the viability of cells suspended in media gassed with oxygen, nitrogen, and 0·275 per cent oxygen in nitrogen, is shown in Fig. 1. The errors shown represent only the statistical error of counting and therefore under-estimate the total error of each point. The lines are the regression lines determined by 'least-square' analysis after giving each point a weight determined by the number of cells counted. The air value at 18·3 per cent survival was the first result to be obtained. Since a slightly different geometry was used during this run, the result has been omitted from the statistical calculations. The point itself has been included in the figure for completeness. The points for air and for 100 per cent oxygen were not significantly different, and both sets were put together in the regression analysis. The slope of the air–oxygen line corresponds to a 37 per cent survival dose of 118·8 ± 3·9 rads, and that of the nitrogen line to a dose of 263·1 ± 16·6 rads. Thus the oxygen–nitrogen ratio *m* is 2·2

Alper and Howard-Flanders[4] found that the sensitivity of bacteria to X-rays at different oxygen concentrations could be fitted by the equation:

$$S(O_2) + SK = S_n m(O_2) + S_n K$$

where S_n is the radiosensitivity in the absence of oxygen (= $1/D_{37}$ dose for nitrogen). S is the radiosensitivity at oxygen tensions (O_2) and m and K are constants. The same equation was found to apply for Ehrlich ascites cells by Deschner and Gray[5]. If these human cells are assumed to obey this equation, then $K = 8{\cdot}5$ μmoles/l., the same order of magnitude as was found for bacteria (7·8) and for mouse tumour cells (5 ± 2). A value of 4·2 has also been reported[6] for bean roots poisoned with cupferron. The plating efficiency varied between 40 and 70 per cent from one experiment to another, but was remarkably constant over all the controls in any one experiment. The experimental procedure alone, including filling the irradiation vessel, gassing with nitrogen for the longest periods used, and all other operations except switching on the X-ray set, gave the same survival as controls which were not subjected to these procedures.

During the cell count a record was also kept of the number of cells in the counting field that appeared to be touching one another. This was usually about 10 per cent of all cells counted, and is the sum of cells actually stuck together and cells which happen to be lying very close to one another. In the worst case, in which this proportion of cells remained in contact throughout the experiment, then the error from this cause would be 5 per cent, or about equal to the counting error. In fact the cells, when plated in bottles, are a thousand times more dilute than in the cell-counting chamber. Thus, the error due to cell clumping would be expected to be very much less than the statistical errors indicated in Fig. 1. The irradiated cell suspension was relatively dilute, between 10^4 and 10^6 metabolizing cells per ml. The total oxygen consumption of the cells would not make a measurable difference to the oxygen tension of the medium, during irradiation in oxygen or air. On the other hand, no help from the cells can be expected during equilibration with nitrogen for the anoxic radiations. Any error here would tend to make the value of *m* too small, and *K* too large. In order to assess the magnitude of these errors, aliquots of the equilibrated anaerobic solution were transferred to a Hersch cell[7] and the residual oxygen measured.

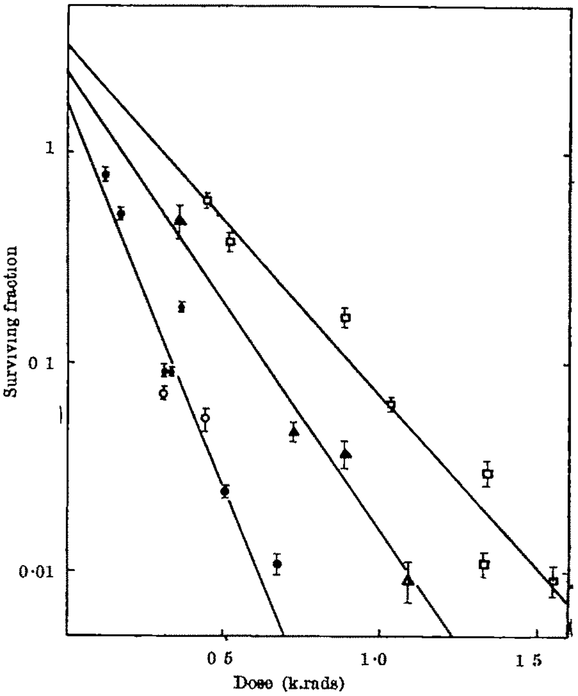

Fig. 1. Survival of human liver cells after 200-kV. X-rays during equilibration with oxygen, ○, air ●, nitrogen □ and 0·275 per cent oxygen in nitrogen △. The lines are the regression lines determined by 'least-square' analysis

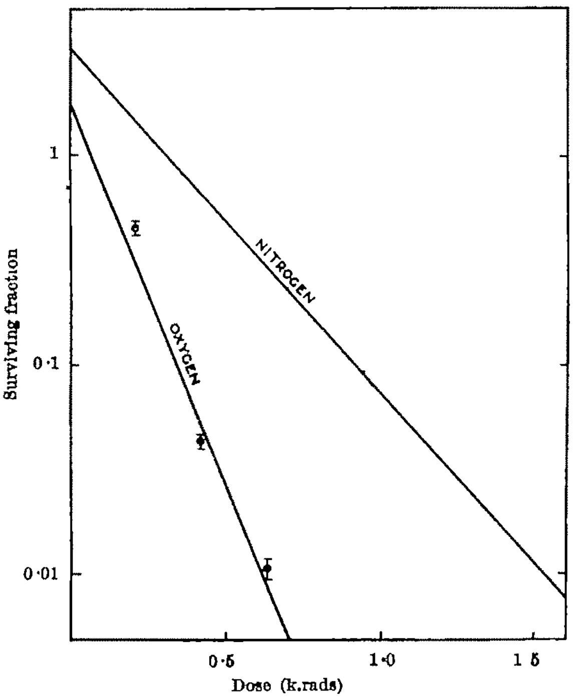

Fig. 2. Survival of human liver cells after 200-kV. X-rays during equilibration with 10 per cent nitric oxide in nitrogen. The oxygen and nitrogen lines are included for reference

These results indicated that the oxygen remaining in solution corresponded to equilibration with about 100 parts/million oxygen in the gas phase. Accurate measurement was made difficult by the foaming nature of the liquid; but if an upper limit of 275 parts/million is assumed then the corresponding value of m would be 2·4 and K would be 7·7 μmole/l. The feeder layer was made by giving bottles, containing a thick layer of growing cells, an exposure dose of 1,320 r. of 200-kV. X-rays. The medium was then poured off, the cells detached from the glass with ethylene-diamine-tetraacetic acid disodium salt, diluted in fresh bicarbonate medium and dispensed in clean bottles. The final concentration was about 10^5 cells per bottle. By extrapolating the air inactivation curve of Fig. 1, and applying the correction used by Morkovin and Feldman[2] for increased radiation-dose due to the proximity of the glass surface, then one colony in 10^2 bottles would be expected. This would introduce a negligible error.

The effect of adding 10 per cent nitric oxide during strict nitrogen anoxia is shown in Fig. 2. The lines are the oxygen and nitrogen lines from Fig. 1 and are included for reference. The conclusion from this experiment is that nitric oxide appears to act in a way similar to oxygen in sensitizing these human cells to X-rays, a phenomenon already found for bacteria by Howard-Flanders[8], for bean roots by Kihlman[9], and for Ehrlich ascites cells by Gray, Green and Hawes[10]. In dry systems nitric oxide acts in the opposite sense, in that it protects anaerobic spores of *Bacillus megaterium*[11] and dry seeds of *Agrostis stolonifera*[12] against damage by X-rays. The overall result is that with respect to the influence of oxygen and nitric oxide on radiosensitivity, human cells in tissue culture behave in a way similar to most other types of cell which have been studied. It is not suggested that cells in tissue culture are identical with those *in vivo*, or that results obtained by inactivating cells in culture can be applied indiscriminately to cells *in vivo*. The process of obtaining cells in tissue culture is by nature one of specifically selecting those cells best able to grow under those conditions supplied.

Nevertheless, the results reported here bear a striking resemblance to the results of irradiating leukæmia cells *in vivo* in live and dead mice reported by Hewitt and Wilson[13] and interpreted by them as the aerobic and anaerobic sensitivities.

I am indebted to Dr. Alma Howard for making the cell counts; to Dr. J. W. Boag, and Dr. R. E. Steele for help in the dosimetry; to Dr. L. H. Gray for suggesting the work and for encouragement and help, and to Mr. J. Steadman and Miss J. Liddon for technical assistance.

INFLUENCE OF CERVICAL SYMPATHECTOMY AND PITUITARY STALK SECTION UPON MILK SECRETION IN GOATS

By G. B. TVERSKOY

I. P. Pavlov Institute of Physiology of the Academy of Sciences of the U.S.S.R., Leningrad

THE hormones of the adenohypophysis play an important part in control of milk secretion. During some days after the operation, hypophysectomy causes a cessation of lactation in spite of an injection of oxytocin—a neurohypophysis hormone, which stimulates milk ejection[1,2]. The control of the hormone-forming function of the adenohypophysis stimulating milk secretion is not yet quite clear. Very little is known about the role that the sympathetic innervation of the adenohypophysis and the nervous and vascular tracts of the pituitary stalk are taking in the control of the hypophysis function stimulating milk secretion. It was therefore considered desirable to examine the influence of cervical sympathectomy and pituitary stalk section upon milk secretion in goats[3-5].

Influence of Cervical Sympathectomy on Milk Secretion

In order to analyse the part the sympathetic innervation of the adenohypophysis is playing in control of milk secretion, the influence of a bilateral cervical sympathectomy upon the secretory process in the mammary gland was studied in an experiment with eight goats. Cervical sympathectomy was performed in two stages at an interval of one month. At each stage the upper and the middle cervical sympathetic ganglia were extirpated from one side, and a piece 2–3 cm. long was cut from the vertebral nerve at the point of its leaving the stellate ganglion. In two goats the stellate ganglia were extirpated from both sides instead of an extirpation of vertebral nerves. The common carotid artery and the jugular vein in the cranial part of the cervix were stripped of their adventitia along 3–3·5 cm. and the vascular walls were carefully treated with 5 per cent aqueous and alcoholic carbolic acid solutions. Two goats underwent a 2-stage control operation of cervical sympathectomy. Cervical sympathetic ganglia of these animals were not extirpated but only exposed.

A unilateral cervical sympathectomy led to a moderate and short decrease in milk secretion. For 10 days after the first operation stage the average amount of milk given by sympathectomized animals was 76·3 per cent of the initial level, while with control-operated goats it was 92·2 per cent. The initial level of milk secretion was achieved after the first operation stage both in control-operated goats and in most of the sympathectomized ones 20–30 days after the operation.

The extirpation of the cervical sympathetic chain from the other side led to a much more profound and prolonged inhibition of milk secretion. During the first 10 days after the second operation stage the average amount of milk given by sympathectomized goats averaged 59·7 per cent of the initial level, while with control-operated animals it was 90·5 per cent. Further, a gradual increase of milk secretion was recorded; but the milk secretion in sympathectomized goats increased extremely slowly. After the second operation stage, the average daily amount of milk given by sympathectomized goats in stall conditions (the animals kept on the same ration as that before the operation) was 80·8 per cent of the initial level, while with the control-operated animals it was 103·4 per cent. Transferring the goats to pasture resulted in an increase of milk secretion in all animals. However, in pasture conditions also the amount of milk secretion in sympathectomized goats (104·6 per cent of the initial level) was lower than in control-operated ones (136·0 per cent).

The above results show that bilateral cervical sympathectomy results in a significant and prolonged inhibition of milk secretion.

Together with a desympathization of the adenohypophysis the cervical sympathectomy causes a desympathization of the neurohypophysis, the thyroid and parathyroid glands[6-8], the hormones of which play an important part in the control of the motor and secretory function of the mammary gland. Special experiments on the measurement of the amount of the residual milk before and after the sympathectomy showed that a desympathization of the neurohypophysis does not cause such disturbances of the milk-ejection reflex, which could lead to an incomplete evacuation of the alveolar part of the gland and, consequently, to an inhibition of milk secretion. If before the operation the amount of the residual milk averaged in six goats 37·8 ml., after the sympathectomy it was 35·0 ml. Neither was the decrease in milk secretion after the cervical sympathectomy a result of a desympathization of the thyroid gland and the internal parathyroid glands. Special experiments showed that a simultaneous denervation of both lobes of the thyroid and of internal parathyroid glands does not result in a decrease in milk secretion. The average daily amount of milk during the first three 10-day periods after this operation—when the sympathectomized goats showed the lowest milk secretion—was, in goat No. 59, 98·6, 100·5 and 100·2 per cent of the initial level and, in goat No. 108, 100·1, 112·5 and 110·6 per cent.

Many authors have demonstrated by their investigations[9-15] that the cervical part of the sympathetic nervous system plays an important part in the control of the hormone-forming function of the adenohypophysis. It is quite possible that in our experiments the decrease in milk secretion after the cervical sympathectomy is due, first of all, to a disturbance of the production of glandular lobe hormones. The decrease of the hormone-forming function of the adenohypophysis could have taken place as a result of a desympathization of the glandular lobe itself as well as of a desympathization of various parts of the brain and, first of all, of the hypothalamus, which plays an important part in the control of the function of the adenohypophysis.

Influence of Pituitary Stalk Section on Milk Secretion

Various authors have investigated the influence of pituitary stalk section on the lactation process in rats and rabbits. These experiments proved that pituitary stalk section in lactating animals brought about starvation of their litters[16-18]. Evidently, it was a result of a disturbance of the milk-ejection reflex[19-21], as the mammary glands of the experimental animals contained during the first post-operative days a sufficient amount of milk[18,22]. If oxytocin was injected into female rabbits after a pituitary stalk section[23], their milk secretion remained at its initial level, although the growth of their litters was slower, evidently due to a change in quality of the milk. As oxytocin causes not only an evacuation of the alveolar part of the mammary gland but probably also leads to an increased production of prolactin[24], these experiments do not allow the conclusion that pituitary stalk section does not cause any decrease in milk secretion. Thus, the results obtained so far do not solve the problem of the influence of pituitary stalk section on the milk secretion process. Owing to this we investigated the influence of pituitary stalk section on the amount of milk secretion.

The operation of section of the pituitary stalk was performed in six goats during their first lactation. Section was carried out by the temporal approach[25]. Four goats underwent a control operation of stalk section. The pituitary stalk of these animals was exposed, but not cut. Three months after the operation all animals were killed and a serial histological analysis of the hypothalamo-hypophyseal region was performed (I. G. Urazov). The results of histological studies showed that three goats (Nos. 112, 313 and 143) underwent complete section of the pituitary stalk. Goat No. 143 showed, contrary to goats Nos. 112 and 313, a thick scar at the site of the section, and its median eminence of the tuber cinereum was very seriously damaged. In three other goats pituitary stalk section was incomplete. Goat No. 146 underwent a complete section of the infundibular stem, whereas the glandular part of the stalk remained, to a great extent, intact. The infundibular stem in goats Nos. 322 and 319 remained intact, while the glandular part of the stalk was partially cut. All goats with a complete stalk section and goat No. 146 showed an atrophy of the neural lobe of the neurohypophysis. In goats Nos 319 and 322 the neural lobe remained intact. The hypophysis of goat No. 143 was significantly decreased in size. All goats showed areas of atrophy in the anterior part of the glandular lobe.

In all goats with a complete section of the pituitary stalk and goat No. 146 the milk-ejection reflex disappeared after the operation, but it reappeared in 7–11 days. However, during some weeks after the operation the milk-ejection reflex was somewhat defective: a prolonged latent period of the reflex and some increase of the amount of residual milk were noted. Goats Nos. 319 and 322 (an intact infundibular stem, a partial section of the glandular part of the stalk) showed a full milk ejection reflex immediately after the operation.

We can now discuss the results of the investigations of the influence of a pituitary stalk section on milk secretion. During the first month after the operation (stall conditions, the same ration as that before the operation) the average daily amount of milk given by goats Nos. 112 and 313 (complete stalk section) was on an average 28·9 per cent of the initial level; goat No. 143 (complete pituitary stalk section with the formation of a thick scar, severe damage of the median eminence) gave 12·6 per cent, three goats with incomplete stalk section 40·5 per cent, and the control-operated animals 55·7 per cent of the initial level. All animals showed an increase of milk secretion on being transferred to pasture conditions. However, in pasture conditions also milk secretion in goats with stalk section was significantly lower than that in the control-operated animals. The average daily amount of milk during the whole post-operative period of investigation (80 days in stall and pasture conditions) was 48·2 per cent of the initial level in goats Nos. 112 and 313 (a complete stalk section), 21·6 per cent in goat No. 143 (complete stalk section with formation of a thick scar, severe damage of the median eminence), 67·1 per cent in three goats with an incomplete stalk section and 77·6 per cent of initial level in control-operated animals. If we assume that during 80 post-operative days the amount of milk secretion in control-operated goats expressed as a percentage of the initial level is 100, the amount of milk secretion in goats Nos. 112 and 313 will average 62·1 per cent in comparison with the milk secretion-level in control-operated goats, in goat No. 143 it will be 27·8 per cent and in three goats with incomplete stalk section, 86·5 per cent. Thus, a complete stalk section leads to significantly decreased milk secretion. Goat No. 143, which had a thick scar formed at the site of the section, and of which the median eminence of the tuber cinereum was severely damaged, showed a very marked decrease of milk secretion An incomplete stalk section leads to a relatively small decrease of milk secretion.

These results prove that nervous and vascular tracts of the pituitary stalk play an important part in the control of the hormone-forming function of the adenohypophysis stimulating milk secretion.

STRUCTURES CORRESPONDING TO TERMINAL BARS AND TERMINAL WEB IN MANY TYPES OF CELLS

By Prof. C. P. LEBLOND, HOLDE PUCHTLER* and Y. CLERMONT

Department of Anatomy, McGill University, Montreal

SURPRISINGLY little is known of the factors influencing the shape of cells. In the intestinal epithelium, two structures were found to have an important role in this respect: the terminal bars, which hold neighbouring cells in close contact, and the terminal web, a layer of fibrils extending across the cell apex between the terminal bars[1]. Interestingly enough, both these structures have the same staining and histochemical properties[1]; in particular, both are stained by successive treatment with tannic acid, phosphomolybdic acid, and amido black (referred to hereafter as the *TPA* technique). The question then arose as to whether cells other than those of the intestinal epithelium contained material with similar staining properties and perhaps with a similar role.

A variety of tissues and organs from male and female adult rats, as well as a few tissues from other animals, were fixed in Carnoy, dehydrated in alcohol and methyl benzoate, sectioned at 2μ and stained by the *TPA* technique[1,2]. A search was then made for structures staining like terminal bars and terminal web.

---

* Fellow of the Damon Runyon Memorial Fund for Cancer Research and of the National Cancer Institute of Canada Present address: Department of Pathology, Medical College of Georgia, Augusta, Ga., U.S.A.

A terminal web which appeared in *TPA* preparations as a single layer extending between the terminal bars was seen not only in the chief cells of the intestinal epithelium (Fig. 1*A*) but also in cells of many other simple epithelia (Table 1, unilayered terminal webs). In all these cells, the terminal web appeared as a thin band located immediately below the apical surface. Using the polarization microscope, Schmidt[3] described a layer just below the striated border of intestinal cells, which exhibited a type of birefringence indicative of the presence of fibrous molecules parallel to the apical surface. Indeed, when sections were cut parallel to the free surface of the intestinal cells and stained with *TPA*, distinct fibrils were often seen within the terminal web.

A systematic survey of the literature revealed that, during the second half of the last century, the terminal web was described by a few authors[4-9], but no name was given to it. This structure was then forgotten, for, to Heidenhain, each unit of the striated border was equivalent to a cilium related to a centriolar granule, and a row of such granules crowded together would appear as a band[10]. This misinterpretation was widely accepted.

Some fifty years later, Sauer[11], who seemed to have been unaware of previous work on the subject, described "a structure which has the appearance of a stained membrane stretched across the end of the cell between the terminal bars" in the ependymal epithelium of amphibian embryos. He stated that this structure is composed of a network of fibrils of such dimension that they are usually not separately visible, and that it may exist in other columnar cells; he proposed the name 'terminal web'. Other authors who observed this structure did not distinguish it from terminal bars (as may be seen, for example, in Figs. 292 and 383 in ref. 12).

The terminal web of the intestinal epithelium was seen in electron microscope pictures of Palade and Porter (quoted in ref. 1) as a filamentous layer extending between the terminal bars and continuous with similar material present in the microvilli of the striated border. Similarly, Palay and Karlin[13] described this terminal web in detail as a dense feltwork of filaments stretched across the cell and from which other filaments extended into the units of the striated border and also into the cytoplasm.

Using the *TPA* technique, a careful examination of the terminal bars was carried out in $2\text{-}\mu$ thick sections of the epithelial cells of the intestine cut parallel to the surface. Under these conditions the terminal bars did not appear to be the uniform rods classically described. Instead, they proved to be composed of juxtaposed granules, giving the appearance of a string of beads. Furthermore, the fibrils of the terminal web were seen to end in these granules. In view of the similarity of the granules with the desmosomes of the Malpighian cells in the epidermis, it was decided to refer to the terminal bar granules by the term 'desmosomes'[14]. Hence, the terminal bar consisted essentially of a series of desmosomes wherein web filaments were confluent.

In the cells of the proximal convoluted tubules of the kidney and the stereociliated cells of the epididymis, cross-sections of the unilayered terminal web appeared finely granulated. In the ciliated cells of the trachea, it was often possible to see a double row of granules connected to the cilia and held within a terminal web ending in desmosomes. Cilia and granules stained with *TPA* and could, therefore, be related to the web.

In the ameloblast, two unilayered webs were present, one at the apex and one at the base of the cell.

In other cell types, the terminal web may be multilayered, each layer being connected with a set of desmosomes. This was the case in the striated ducts of salivary glands (Fig. 1*B*, Table 1).

The terminal bar-terminal web complex is organized quite differently in some cells where fibres attached to the terminal bars extended from the apex of the cell towards the base in a pillar-like fashion. This was observed, for example, in the uterine epithelium. An extreme example of this arrangement was seen in the pillar and outer phalangeal cells of the organ of Corti, where the bundles of tonofibrils forming the pillars proved to stain with *TPA* (Fig. 1*C*).

Another arrangement was exemplified by the goblet cells of the intestinal epithelium or the surface mucous cells of the stomach in which the *TPA*-stained structure was lacy and basket-like, enclosing the mucous droplet (Fig. 1*D*). In addition, these cells had a pillar-like bundle of fibrils going from the terminal bars to the cell base (Fig. 1*D*).

A special type of terminal web was present in some exocrine glands, for example, in the acinar cells of the pancreas (Fig. 1*E*). The apex of the cell had a narrow rectangular surface, supported by a terminal web limited by terminal bars (composed of desmosomes). From these, fibrils extended into the cytoplasm in various directions to form an intricate network which outlined spaces enclosing the zymogenic granules. Such a complex web was not always restricted to the cell apex, but also extended laterally to the regions facing the intercellular canalicules.

Table 1. LIST OF THE CELL WEBS IDENTIFIED SO FAR

- Terminal web
  - Unilayered (Fig. 1*A*)
    - Non-ciliated cells; chief cell of intestinal epithelium. Epithelial cells from: gall bladder, pancreatic duct, seminal vesicle, prostate, coagulating gland, uterus, ascending and descending limbs of Henle's loop, distal convoluted and collecting tubules, lacrimal gland, sweat gland, mammary gland, epididymis, vas deferens, thyroid.
    - Ciliated cells from: bronchus, trachea, ampulla of Fallopian tube, vas deferens.
    - Cells of connective tissue origin: odontoblasts, reticulo-endothelial cells of splenic sinuses (basal plate).
  - Multilayered (Fig. 1*B*)
    - Epithelial cells from: intralobular (striated) and intercalated ducts of sublingual parotid, submaxillary; intralobular duct of pancreas.
    - Ducts of orbital gland, sweat gland.
    - Bile ducts.
    - Surface cell of transitional epithelium.
  - With network (Fig. 1*E*)
    - Glandular epithelial cells of pancreas, serous cells of salivary glands, zymogenic cells of gastric glands, Paneth cells; mucous cells of Brunner's gland.
- Pillar-like web (Fig. 1*C*)
  - Non-ciliated epithelial cells of Fallopian tube.
  - Epithelial cells in stria vascularis of cochlear duct.
  - Supporting cells of the organ of Corti and of the maculæ (Fig. 1*D*).
  - Goblet cells of intestinal and olfactory epithelium.
  - Surface mucous cells of stomach.
  - 'Flame-like' ciliated cells in pancreatic duct.
- Circumferential web
  - Partial (Fig. 1*F*): islets of Langerhans cells, corpus luteum cells.
  - Complete (Fig. 1*G*, 1*H*): parenchymal cells of liver, adrenal cortex and pituitary: sebaceous cell.
- Tubular web (Fig. 1*I*)
  - Spermatid.
- Dispersed web tonofibrils (Fig. 1*J*)
  - Epidermis.
  - Stratified squamous epithelia of tongue, œsophagus, forestomach and vagina.
- Contractile web myofibrils (Fig. 1*K*)
  - Striated muscle fibres of skeletal and heart muscle.
  - Smooth muscle fibres.
  - Myoepithelial cells.

Nature, June 4, 1960, p. 786

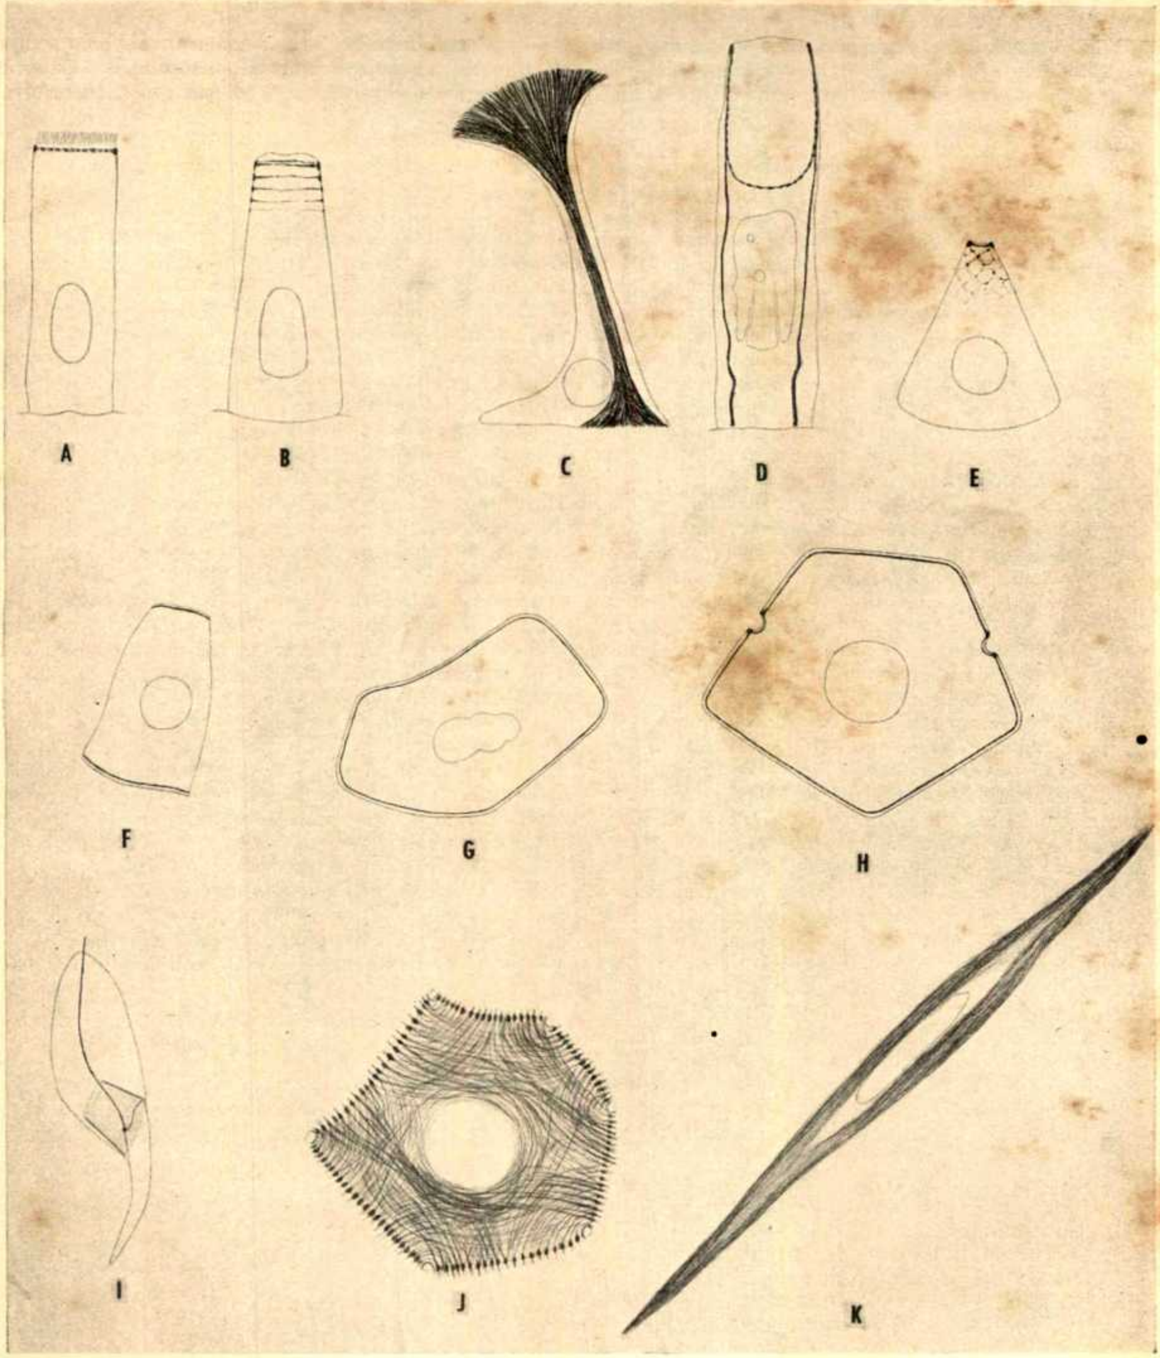

Fig. 1. Diagrammatic representation of various types of 'cell web' as revealed by the tannic acid–phosphomolybdic acid–amido black (*TPA*) technique in 2-μ sections. Cells drawn from rat tissues unless specified

A, chief cell of small intestine epithelium; a fibrous unilayered terminal web is seen at the apex of the cell immediately below the striated border. At the two ends of the web, the terminal bars are seen in cross-section

B, cell from a striated duct of a salivary gland showing a multilayered terminal web. Each layer of the cell web is connected with terminal bars

C, pillar cell of the organ of Corti in which the web filaments are packed into a dense bundle or pillar extending from the base to the apex of the cell

D, surface mucous cell of the stomach (from salamander) with a complex web containing pillar-like fibres as well as a network of fibres arranged as a basket separating the mucous droplet from the cytoplasm. Note that this cell web is attached to terminal bars

E, acinar cell of the pancreas showing a terminal web facing the lumen of acinus. The fibrous web is located between terminal bars, from which a network of filaments extends into the cytoplasm

F, beta-cell of islet of Langerhans showing a partial circumferential web lining two surfaces of the cell (above and below). These surfaces are those which face blood sinusoids

G, cell of sebaceous gland (from horse) showing a complete circumferential web under the cell membrane

H, liver cell with a complete circumferential web. The cell surface is indented in two places (right and left of diagram) so as to make up bile canalicules with the adjacent cells. The circumferential web is attached to bars running longitudinally in the walls of bile canalicules. The cell membrane lining the canalicules is subtended by a hemicylindrical web

I, in spermatids, the caudal tube (also called manchette) constitutes the web. The caudal tube is a transitory structure which appears as the nucleus of the spermatid, elongates to become sickle shaped and disappears before the cell completes its final transformation into a spermatozoon. This sleeve-like structure is located at the base of the nucleus and surrounds centrioles and flagellum

J, cell from the Malpighian layer of the skin (chestnut of the horse) showing intensely stained tonofibrils attached to desmosomes. Since the tonofibrils are distributed throughout the cytoplasm, they are considered as forming a dispersed web

K, smooth muscle fibre with well-stained myofibrils (contractile web)

This was particularly clear in parotid and external orbital glands.

So far, terminal webs have been described in simple epithelial cells. A terminal web may exist in other cell types, for example, in the odontoblast—a connective tissue cell adapted to the elaboration of dentinal matrix. In the spleen, the reticulo-endothelial cells lining the venous sinuses contained a structure described under the name 'basal plate', which extended over the entire base of the cell[15,16]. This stained with *TPA*.

Cells which were not distinctly polarized occasionally contained a *TPA*-staining fibrous layer located immediately below the cytoplasmic membrane. This structure will be referred to as circumferential web. In the cells of the islets of Langerhans, the circumferential web appeared incomplete, as it was clearly seen only at the surfaces in contact with capillaries (Fig. 1*F*). In the cells of the sebaceous glands, the circumferential web clearly extended all around the cell, thus forming a complete lining under the cell membrane (Fig. 1*G*).

The parenchymal cells of the liver also had a complete circumferential web, which reinforced bile canalicules (Fig. 1*H*). When two adjacent cells included a bile canalicule at their interface, each cell provided half the wall of the canalicule, in the form of a hemicylinder composed of cell membrane and underlying web. Junction of the two half-cylinders was ensured by longitudinal bars identical in appearance and staining properties with the terminal bars of epithelial cells, and like them, composed of a row of desmosomes.

The membranous structure described in spermatids under the name caudal tube was composed of longitudinal filaments which stained with *TPA* (Fig. 1*I*). This 'tubular web' extended caudally from the posterior region of the nucleus and enclosed in its cuff-like membrane the centrioles and the proximal part of the flagellum, both of which also stained.

The tonofibrils present in the cells of the Malpighian layers in epidermis and stratified squamous epithelia stained well with *TPA*. The bead-like structures or desmosomes which were present along the cell membranes and in which there was a confluence of the tonofibrils also stained intensely (Fig. 1*J*). Therefore, these two structures may correspond to the terminal bar-terminal web complex. The tonofibrils would thus be the web of these cells and, since they were present throughout the cytoplasm, they may be said to make up a dispersed web.

The myofibrils of striated and smooth muscle fibres (Fig. 1*K*) stained with *TPA*. In the case of cardiac muscle fibres (Fig. 1*K*), the myofibrils were seen to terminate in the intercalated disks, which were composed of intensely stained granules similar to desmosomes. Hence, myofibrils were considered to be homologous to the web of other cells and would therefore constitute a contractile web. Myoepithelial cells contained fibrils which were distinctly stained by the *TPA* technique, and would also constitute a contractile web.

Finally, the spindle fibres seen at metaphase during either mitosis or meiosis stained with *TPA*. The centrioles were also well stained, not only when observed at the two extremities of the spindle at metaphase but also at other stages of mitosis and even in resting cells. Perhaps spindle fibres and centrioles could be related to the cell web. Such relation might give significance to the suggestion that towards the end of mitosis the equatorial portion of spindle fibres gives rise to terminal bars[11].

Is it legitimate to link a variety of structures on the basis of similar staining ability ? Before answering this question, it may be recalled that many years ago Zimmermann reported that structures similar to terminal bars were present in many types of cells[17]. It would therefore be reasonable to suppose that the terminal web of the intestinal epithelium also has a counterpart in many cells.

However, when the *TPA* technique was applied to various tissues in a search for structures corresponding to the terminal web, difficulties arose, as the nucleus and various cytoplasmic materials often stained to some extent. It was therefore necessary to define the terminal web as precisely as possible. In the epithelial cells of the intestine this structure exhibited three characteristic features : (1) it stained by the *TPA* technique ; (2) it stained with iron hæmatoxylin and with a series of histochemical stains indicating the presence of basic proteins (somewhat different from usual basic proteins and particularly from collagen), but there was no reaction for carbohydrates, fats or nucleic acids ; (3) when the terminal web was cut parallel to the plane of section, it was often possible with the *TPA* or iron hæmatoxylin techniques to distinguish fine fibrils. (Since electron micrographs of this structure showed it to be composed of fine filaments too minute to be resolved by the light microscope[13], these filaments must be arranged in bundles which appear as fibrils after *TPA* staining.)

The various types of web listed in Table 1 stained with *TPA* and tended to be fibrillar in appearance ; furthermore, those that have been analysed histochemically (as will be reported elsewhere by Holde Puchtler) gave the histochemical reactions of basic proteins. Hence, it was concluded that these various forms represented different structural arrangements of the same cell organelle, for which we propose the name 'cell web'.

It has been pointed out that, when sections of intestinal epithelium were cut parallel to the cell surface, the terminal bars of the epithelial cells were not uniform rods, but rather rows of juxtaposed granules, referred to in the present work as 'desmosomes'. The desmosomes had exactly the same staining (*TPA*, iron hæmatoxylin) and histochemical properties (being composed of basic proteins) as the cell web itself. Investigation of many cell types often showed structures with the same characters as the terminal bars of the intestinal epithelium. This was true not only of the terminal bars seen in simple epithelia at one (Fig. 1*A*) or several levels (Fig. 1*B*) but also of the longitudinal bars seen along bile canalicules and intercellular canalicules in exocrine acini, and of the intercalated disks in cardiac muscle fibres. All these structures were composed of rows of desmosomes with the same properties as the individual desmosomes of the epidermal prickle cells. The fact that the histochemical properties of desmosomes were identical to those of the web itself suggested that at least part of the desmosomes would arise from aggregation of web filaments in certain areas of the cell membrane.

There were a few cells, particularly connective tissue and blood cells, in which neither web nor desmosomes were distinguishable. However, a faint *TPA* staining of fibrillar structures could be seen occasionally. For example, mature plasma cells contained a sharply staining centriole from which fibrils radiated. Furthermore, whenever cells divided, all of them, including connective tissue cells, showed *TPA* staining of centrioles and spindle fibres, which, therefore, may be related to web filaments. Would connective tissue cells and blood cells have a web too scanty for adequate staining ? If so, the web might well be present in all cells of the rat. Whatever the answer to this question may eventually be, it was clear that a large majority of the cells in this species contained a cell web. Furthermore, preliminary observations suggested that structures corresponding to the cell web were present in other mammals and in other animal groups, making up structures that in protozoa and other cells have been described as resulting from cortical or ectoplasmic differentiation[20].

What are the functions of cell web and desmosomes ? *A priori*, the two main factors influencing the shape of a cell are its relation with neighbouring elements and the structural qualities of its intracellular components. Since, in the intestinal epithelium the desmosomes connect each cell with its neighbours, while the cell web functions as a support for the cell apex[1], these structures must play a part in maintaining cell shape.

Similar observations may be made in tissues other than simple epithelia. In liver cells, the desmosomes and web are located so as to account for the well-known rigidity of bile canalicules[19]. In the ear, the stiff pillars of Corti are composed of densely packed web fibrils. The tubular web (caudal tube) of the spermatids, as a result of its firmness, may be seen to push the cytoplasmic membrane aside. In contrast, the cells with little or no stainable web—leucocytes and connective tissue cells—have no definite shape. It is concluded that, while more proof of the rigidity of the web is required, perhaps by testing with micro-dissection needles, circumstantial evidence favours a role of this web in giving firmness and shape to the cell.

In conclusion, the cell contains a fibrillar system —for which we propose the name 'cell web'—which stains with the *TPA* technique (tannic acid, phosphomolybdic acid and amido black) and is arranged in a characteristic manner in any given cell type. In simple epithelia, the cell web predominates in the apical region of the cell, where it is arranged in single or multiple layers of fibrils, which join the granules composing the terminal bars. (These granules are referred to as desmosomes.) In many parenchymal cells—liver, adrenal, etc.—the web makes up a complete lining under the cell membrane and its fibrils enter desmosomes, which build up structures similar to terminal bars. In stratified epithelia, the web is believed to consist of the well-known tonofibrils which enter individual desmosomes, and in muscular tissues, of the myofibrils which, in cardiac muscles at least, join the desmosomes of intercalated disks. A cell web has been seen in many other cell types (for example, spermatids and reticulo-endothelial cells of spleen). It is suggested that the fibrils of the cell web are endowed with a fair degree of firmness, and combine with the desmosomes in shaping the cell.

DETECTION AND ESTIMATION OF A FACIAL ECZEMA TOXIN, SPORIDESMIN

By G. R. RUSSELL
Ruakura Animal Research Station, Hamilton, New Zealand

THE disease of sheep known in New Zealand as facial eczema is now believed to be due to the presence on the pasture of a fungus, *Sporidesmium bakeri*[1]. The hepatotoxic principle has been isolated and crystallized[2]. Following the results of Synge and White, spots of the toxin were chromatographed on paper in water solvent and sprayed with sulphur-reacting reagents. Of those tried, only the azide-iodine reagent[3] showed a positive reaction. This reagent has now been developed in two ways—as a spray for chromatograms, and as a titration reagent for the toxin.

Run in a descending water solvent, the toxin appears to streak, possibly due to adsorption on the paper, and this may be even more pronounced if the applied spot is an impure extract. Consequently a variety of different solvent systems was tried, and finally the method adopted was to run a descending chromatogram on Whatman No. 4 paper, using methanol/water (50/50) as a solvent. This system does not entirely preclude streaking of the toxin spot, but it does reduce streaking when crude extracts are chromatographed. An azide-iodine reaction with lowered iodine content (0·005 N iodine in 0·1 N potassium iodide, containing 1·5 per cent sodium azide) has been found most satisfactory for detection of the spot. The paper is dried and sprayed with this reagent, when the toxin appears as a white spot on a brown background. After a few minutes the paper is oversprayed with 1 per cent aqueous starch solution, which reveals the white spots against a blue background, slowly fading to a permanent brown colour.

When running several chromatograms of toxic extracts in this manner it appeared that there was some relationship between the amount of toxin present and the size of the spot on the chromatogram. A standard solution of sporidesmin (with carbon tetrachloride of crystallization) in alcohol was prepared. Chromatograms of this were run, with levels of toxin applied at the origin ranging from 0·25 µgm. to 5 µgm., and over this range there was a distinct increase of spot size with the amounts present.

Using this chromatogram as a standard it has been possible to estimate approximately the amount of toxin present in a sample by visual comparison of the spot size using known amounts of toxin on the same paper. The R_F of the pure toxin is 0·88, while the spots appearing in samples are usually of lower R_F 0·81, and sometimes streaking. It is sometimes necessary to run a preliminary chromatogram with an unknown sample to get some idea of the percentage of toxin present, as the toxin spot must be within the range of the standards.

It was considered that catalysis of the iodine–azide reaction by the toxin might be utilized as the basis of a titration method for estimation of the toxin. Reagents were prepared of 0·01 N iodine in potassium iodide solution containing 3 per cent sodium azide[4] and 0·01 N sodium arsenite. The sodium arsenite solution was used in a Conway microburette. Samples of the pure toxin in alcohol solution were put into small dishes, evaporated and excess iodine–azide solution added. The dish was sealed with a ground-glass lid, and after 5 min. the unreacting iodine was titrated with sodium arsenite, using starch indicator. The titrations were carried out in duplicate, and blanks always titrated. Using 0·5 ml. of azide–iodine reagent there was a straight-line relationship between the amount of toxin added and the iodine consumed by the azide–iodine reaction, within the range up to 5 µgm. toxin. When higher amounts of toxin are required to be titrated, greater excess of the iodine–azide solution is required. Titration carried out with iodine solution without azide present shows that uptake of iodine by the toxin is insignificant under these conditions.

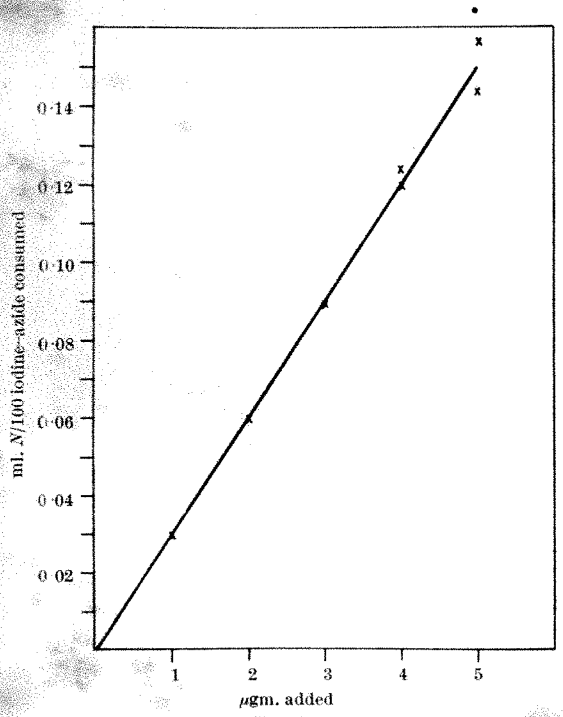

Fig. 1. Titration of toxin

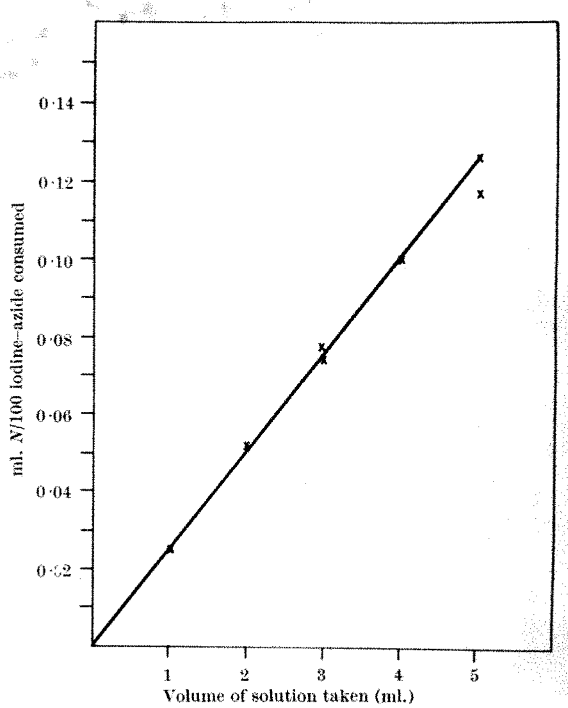

Fig. 2. Titration of spore extract (10 mgm./ml. ethanol)

Methanol extracts of spores at the petroleum ether wash stage of purification[2] were made up in alcohol solution and the insoluble material allowed to settle out. Aliquots of this solution were titrated as above, and the iodine consumption appeared to be proportional to the amount of extract added. It therefore appears that even in these crude extracts, a measure of the iodine consumption by the azide–iodine reaction may be used to estimate the amount of toxin present. The following is a typical example of a toxic extract of spores; 10 mgm. of the extract at the petroleum ether wash stage was made up to 1 ml. in alcohol. Chromatography of aliquots of this solution showed that the only azide–iodine reacting spots present were due to the toxin, and it was estimated by the comparative method that the extract is 4 per cent toxin.

Titration of a series of aliquots of this solution, using information from Figs. 1 and 2, indicates that the extract is 4·2 per cent toxin. This result is in good agreement with the level of toxicity obtained by biological tests, carried out by colleagues in these laboratories (based on production of keratitis of rabbit's eye, injury to HeLa cells and characteristic biliary lesions produced in the liver of rabbits).

The results of this suggests that the method so far used may be applicable to the detection and estimation of the toxin in many media, and work is in progress to estimate toxin in pasture.

A more complete study of the catalysis of the azide–iodine reaction by the toxin will be made in the future.

Analysis of Accelerated Motion in the Theory of Relativity

CONVENTIONAL treatments of accelerated motion in the theory of relativity have led to certain difficulties of interpretation. Thus, Crampin, McCrea and McNally[1] mention the lack of uniformity in the correspondence of events as depicted by the transformation of Born and Biem. Again, Donahue and Leffert[2] and Moller[3] discuss certain reversals in the apparent gravitational field of an accelerated body. I have found[4] that these difficulties may be avoided by simpler analysis based on the use of restricted conformal transformations. In the conformal theory the velocity of light remains constant even for experimenters in accelerated motion.

The problem considered is that of rectilinear motion with a variable velocity v. I introduce two co-ordinate systems, A, (x,t) and B, (x',t'). The motion takes place along the x or x' axis.

The correspondence between the xt and $x't'$ systems may be expressed quite simply by the transformation:

$$\begin{aligned} x' + t' &= F(x + t) \\ x' - t' &= G(x - t) \end{aligned} \tag{1}$$

The velocity is given by:

$$v = \frac{g - f}{g + f} \tag{2}$$

Here f and g are the derivatives of F and G with respect to their arguments $x \pm t$. I now suppose that A, (x,t) is an inertial system, and in order to satisfy the relation of equivalent scale in the vicinity of B, I apply the boundary condition:

$$fg = 1 \text{ along } x' = 0 \tag{3}$$

If the motion of B is given then this relation, together with equation (2), is sufficient to determine the functions F and G. As determined in this way, this transformation becomes tangent to instantaneous Lorentz transformations all along the path of B and in the case of uniform velocity reduces to the Lorentz transformation everywhere.

Fig. 2. Example showing application of restricted conformal transformations

Fig. 1 shows how such $x't'$ co-ordinates may be constructed graphically with the aid of periodic time signals originating in the B system. Such signals generate a family of outgoing waves, represented by the characteristic lines $t \pm x =$ constant. If these lines are now extended backward, a corresponding family of incoming signals will be represented. Intersections of the characteristic lines may then be identified with the events of synchronization of the various clocks of the B system.

Extension of the theory of relativity by conformal transformations in four dimensions was considered many years ago by Bateman[5]. It seems that the group $C4$ admits only restricted motions, and of these the Lorentz transformation alone maintains equality in the scale relation. Therefore, we do not speak of a conformal transformation of the whole space. However, by restricting attention to a narrow cylindrical region around the x-axis, conformal mappings can be employed locally, so that:

$$ds'^2 = fg(dt^2 - dx^2 - dy^2 - dz^2) \tag{4}$$

for $y^2 + z^2 \rightarrow 0$.

Fig. 2 illustrates a simple example of the type discussed in connexion with the clock paradox. At $t = 0$, B starts away from A at the velocity 3/5. At $t = 5$, B reverses its motion and returns. Values of f and g in various regions are indicated between characteristic signal lines. The condition of local scale equivalence, $fg = 1$, results in a 20 per cent reduction of the elapsed time along the path of B. In addition to the time discrepancy, there appears also a discrepancy in the relative spatial displacements.

GEOPHYSICS

Anisotropy of Susceptibility and the Natural Remanent Magnetization of Some Welsh Slates

In order to investigate the effect of the deformation associated with mountain building upon the anisotropy of susceptibility and the natural remanent magnetization of rocks, approximately a hundred specimens were prepared for measurement from some fifty samples of Lower Palæozoic Welsh slates cleaved during the Caledonian orogeny. The anisotropy in fields of less than two œrsted was determined with a transformer bridge[1] and the natural remanent magnetization with an astatic magnetometer. The results showed that the cleavage is a plane of high susceptibility, and that the remanent vector is parallel to it. In some of the slates it appears that the direction of natural remanent magnetization has been controlled by the anisotropic susceptibility, and in others that the pattern of anisotropy and the natural remanent magnetization have been aligned with the cleavage independently. I am indebted to Dr. J. C. Belshé and Dr. R. W. Girdler, with whose help the susceptibility work was begun.

It was only possible to measure the direction of natural remanent magnetization of the specimens from four sites, the remainder being too weakly magnetized. Without exception the vectors lay close to the cleavage plane; fifty of the fifty-six measured were within 20° of it and twenty-six within 5°. Figs. 1*a* and 1*b* are equal-area projections showing the direction of natural remanent magnetization relative to the field orientation of the rocks. In the first plot (Fig. 1*a*) the mean directions of natural remanent magnetization of the specimens from three of the sites have been joined by great circles to their respective cleavage planes. The scatter about these mean directions is small, for example, the radius of the cone of 90 per cent probability (α), and the Fisher precision factor (k)[2] were 8° and 29 respectively for the Dolgelley slates. The mean directions are related to the cleavage and therefore distinct for each site, but they are nevertheless in the same general direction as previous workers have found in the nearest rocks of Devonian age[3]. The natural remanent magnetization of these slates is due to pyrrhotite. In contrast, the remanent vectors of the Bethesda slates (Fig. 1*b*) have neither a small scatter nor directions comparable to any suggested for British rocks. Their magnetization is due to hæmatite. The remanence of the Bethesda slates is almost unaffected by alternating-current demagnetization up to fields of about 400 œrsted, while the magnetization of the pyrrhotite-controlled specimens is wiped out by fields of 250 œrsted.

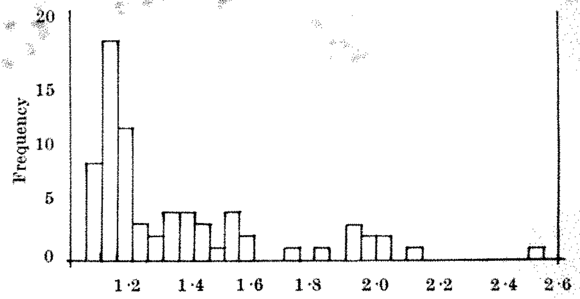

Fig. 2. Histogram of anisotropy ratios of Welsh slates

Fig. 2 is a histogram of the anisotropy ratios found in the slates. Defining the P factor as the ratio of maximum to minimum susceptibility, we see that no P factor of less than 1·05 was observed while values between 1·1 and 1·2 were the most common. The ferromagnetic mineral in those specimens with P factors greater than 1·4 was shown by X-ray analysis and Curie-point determination to be invariably pyrrhotite. The anisotropy of the Welsh slates exceeded that of the few uncleaved sedimentary and igneous rocks which were collected alongside them for comparison.

To consider the relation between the pattern of anisotropy and the cleavage, we now compare the direction of minimum susceptibility and the pole to the cleavage plane (Fig. 3). The similarity of these two directions demonstrates that the maximum intermediate plane of the susceptibility magnitude ellipsoid is approximately parallel to the cleavage plane. The anisotropy of the slates will be due either to shape effect or to crystalline anisotropy of the ferromagnetic minerals. If it is caused by the former then there will be preferred orientations of the long axes of grains of intrinsically isotropic susceptibility. If it is caused by the latter the ferromagnetic grains must have preferred crystallographic orientations. Either possibility is easy to imagine in a slate and both are observable in various minerals, particularly the micas.

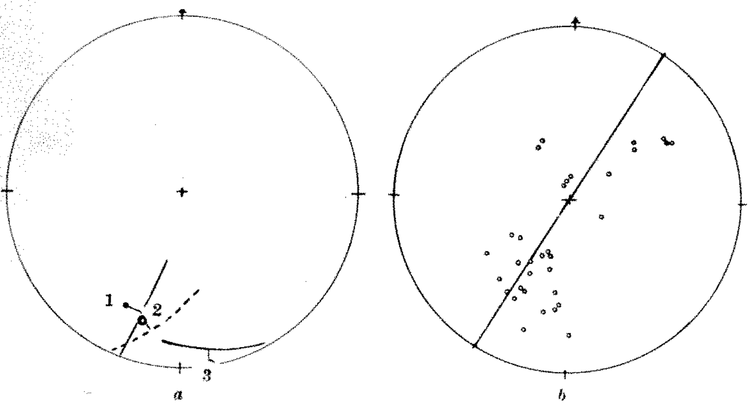

Fig. 1. The direction of natural remanent magnetization and the orientation of the cleavage. (*a*) Slates from Barmouth (1), Talsarnau (2) and Dolgelley (3). (*b*) Cambrian slates from Bethesda. Upper hemisphere poles and great circles, ○ ⁄ ; lower hemisphere poles and great circles, ● ⁄

In reflected light the pyrrhotite in the markedly anisotropic slates can be seen to be in the form of platey grains lying parallel to the cleavage plane. However, the anisotropy of the slates is not likely to be due to shape because the susceptibility of the pyrrhotite is too small for the effect of the anisotropic demagnetizing field to be observed[4]; powders of this pyrrhotite have a susceptibility of 8×10^{-3} e.m.u./cm.^{3}. Since pyrrhotite is known to have an easy plane of magnetization and a difficult direction normal to the plane, the observed anisotropy of the slates

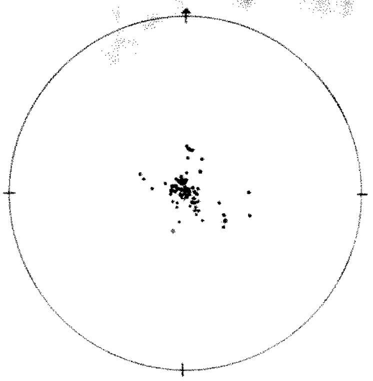

Fig. 3. Equal area projection of the minimum susceptibility directions with the cleavage plane horizontal. Pole to the cleavage, ⊕

could be due to an alignment of the high-susceptibility basal planes parallel to the cleavage. This explanation was confirmed by further examination of the optically uniaxial pyrrhotite in reflected light. In sections cut parallel to the cleavage the grains are predominantly almost isotropic, while in sections perpendicular to cleavage they invariably show distinct anisotropism and moreover they extinguish parallel to the plane of the plates. Hence the platey grains represent the common tabular habit of pyrrhotite, and therefore there is an alignment of the basal planes parallel to the cleavage and this causes the slates to be magnetically anisotropic.

The thermo-remanent magnetization of anisotropic substances has been shown to be deflected from the ambient external field towards the direction of high susceptibility[4,5]. Three specimens of the Crogenon slates, which have pyrrhotite, were given a thermo-remanent magnetization and a mean deviation of 30° recorded. Since the Curie-point of pyrrhotite is 320° C., which may have been exceeded during the metamorphism associated with the Caledonian orogeny, it is possible that the natural remanent magnetization had a thermal origin and is parallel to a component of the Devonian geomagnetic field in the basal planes of the pyrrhotite. Such a mechanism of magnetization does not account for the direction of the natural remanent magnetization of the Bethesda slates because their anisotropy is too small to produce the necessary deviation from the ambient field. Thus we must look to some more direct effect of the stress environment which produced the cleavage.

The magnetic susceptibility of slates is then distinctly anisotropic. The pattern of anisotropy and the direction of natural remanent magnetization are related to the cleavage and were, therefore, determined either directly or indirectly by the stress environment during metamorphism. It is important to note the possible indirect effect of stress demonstrated, for example, by the anisotropic Ballachulish slates in which it is known[6] that the pyrrhotite formed after the slates were cleaved. The mere presence of a foliation such as a cleavage or bedding plane can cause anisotropy if secondary pyrrhotite forms. The effect of anisotropic susceptibility upon magnetization is sufficient to account for the direction of natural remanent magnetization in the slates with pyrrhotite, but not of those with hæmatite. Thus it has been possible to explain the nature of the anisotropic susceptibility of some of the slates in terms of re-crystallization controlled by past stress environments and it should not be difficult to extend this work. However, the nature of the remanent magnetization and the means by which the stress controls its direction are still uncertain.

PHYSICS

Structure of High-Rank Coals deduced from Helium Densities

Wandless and Macrae[1] were the first to show that a relationship exists between the true density of coals and their hydrogen content. Franklin[2] extended this work, and on plotting the specific volume (1/*d*) of a number of coals found that an extrapolation of the straight line drawn through the points, to zero hydrogen content, did not pass through the point for graphite (Fig. 1). For this reason she proposed the hypothesis that the structure of coals is "markedly different from that of graphite". This is in disagreement with the generally accepted theory that coal molecules are basically fused, polynuclear aromatic

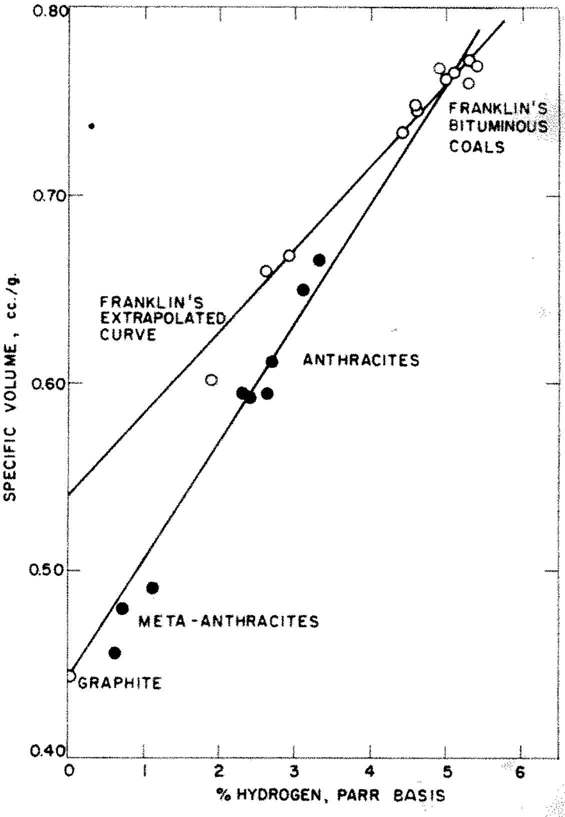

Fig. 1. Specific volume of coals versus percentage hydrogen

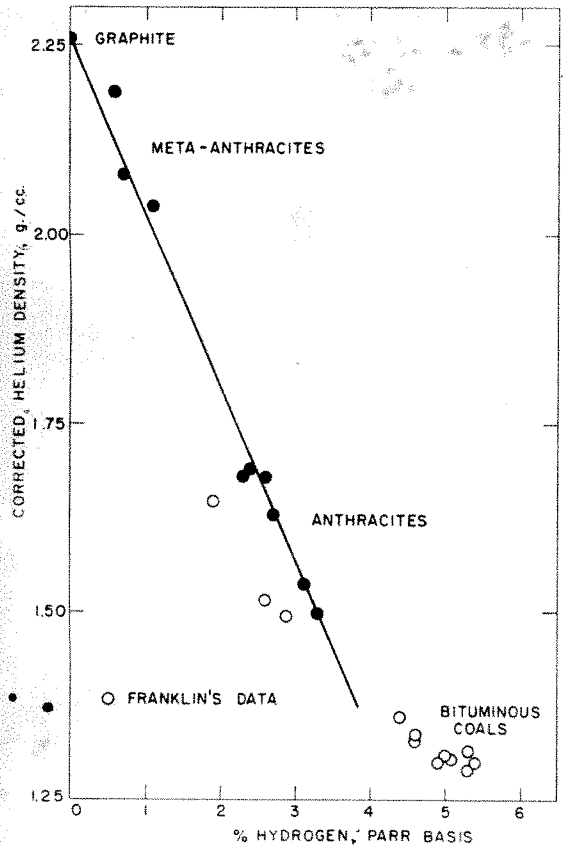

Fig. 2. Density of coals versus percentage hydrogen

structures, that is, islets of small graphitic monolayers which may or may not be associated vertically, and to which various aliphatic groupings are attached. This is suggested in van Krevelen and Chermin's[3] plot of density of coals versus carbon content, in which the density of graphite is considered to be "the true limit" of coalification.

If coals, especially those of high rank, are composed of molecules which are basically related to graphite, then the hydrogen atoms present in these coals should decrease the density of the coals in proportion to the amount of hydrogen present. To test this hypothesis, we have determined the helium densities of three meta-anthracites and six anthracites (Table 1). These were corrected for mineral matter by the method of Wandless and Macrae[1] and the corrected densities plotted against hydrogen content in Fig. 2. The specific volumes of these coals are also plotted in Fig. 1. It will be observed that density gives a closer correlation than specific volume for the high-rank coals. On the other hand, specific volume gives a fair correlation that extends into the bituminous coal region. In either case, it will be observed that graphite constitutes the end-point of these plots, and that there is no reason to assume that high-rank coals have a carbon structure basically different from that of graphite.

† Pre-Cambrian algal coal, reputed to be the oldest known coal in the world.

The equation for the line drawn through the densities of the high-rank coals in Fig. 2 is $y = 2 \cdot 26 - 0 \cdot 23x$, where y is density and x is the percentage hydrogen. As will be observed in Fig. 2 this correlation must not be extended too far down the coal series. Coals having hydrogen contents greater than about 3·5 per cent tend to have densities greater than the equation predicts. No doubt this is due to the increasing amount of oxygen and other atoms introduced along with hydrogen into the lower rank coals, and on this basis the density of these coals should not be expected to correlate with their hydrogen content as the only variable affecting density.

A further test of the reliability of the equation above can be made with three high-rank coals investigated by Dulhunty and Penrose[4]. The hydrogen contents of these coals are 2·0, 3·1 and 3·6 per cent. These values give calculated densities of 1·800, 1·547 and 1·432 respectively, which compare favourably with the observed densities of 1·804, 1·512 and 1·430 in the same order.

Fairly good densities of coals so far as the bituminous rank may be calculated using the equation for the line drawn through the specific volumes of the coals in Fig. 1. The equation for this line is $y = 0 \cdot 442 + 0 \cdot 064x$; where y is the specific volume and x is the percentage hydrogen. By calculating the specific volume of a coal with this equation, the density is easily obtained as the reciprocal.

Effect of Carrier Gas on the Sensitivity of Thermal Conductivity Detectors

THE sensitivity of thermal conductivity detectors is proportional to the variation of the wire temperature (t) with the volume fraction (x) of the vapour in the carrier gas. Ray[1] has shown that for small values of x:

$$dt/dx = a(k_1 - k_2)/k_1^2 \qquad (1)$$

where k_1 and k_2 are the thermal conductivities of carrier gas and vapour, respectively, and a is a constant depending on the geometry of the detector cell and the square of the wire current. This equation, and the conclusion drawn by Ray from it, has led to a discussion[2-6] of the merits of carrier gases of high and low thermal conductivity with respect to the sensitivity of thermal conductivity detectors.

It should be noted, however, that Ray's equation is valid only when the thermal conductivity of the mixture satisfies the linear relation $k_m = (1 - x)\, k_1 + xk_2$. In general, thermal conductivities of mixtures are not a linear function of the composition, although quite often, at high dilutions, a linear relation can be obtained by substitution of an effective k_2 for k_2 (ref. 7). However, the value of this effective k_2 depends on the choice of the carrier gas.

It is also possible to replace the linear k_m versus x relation by a more widely applicable empirical equation[8]. This would lead to very complicated formulæ. Instead, we will consider another extreme relation, for example, $1/k_m = (1 - x)/k_1 + x/k_2$ (refs. 9 and 10). Application of this equation gives:

$$\mathrm{d}t/\mathrm{d}x = a(k_1 - k_2)/k_1 k_2 \qquad (2)$$

In contrast with equation 1, equation 2 predicts a higher sensitivity of the detector for carrier gases of high thermal conductivity.

Thermal conductivities at the average cell temperature were taken from Berl, W. G., "Physical Methods in Chemical Analysis", 2 (New York, 1931). The temperature was calculated by using the equation for the heat balance in the detector cell.

Table 2. EXPERIMENTAL AND CALCULATED DETECTOR SENSITIVITIES FOR PROPANE IN HYDROGEN AND NITROGEN ($x \sim 0{\cdot}025$)

i (m.amp.)	Hydrogen			Nitrogen		
	Exp.	Eq. (1)	Eq. (2)	Exp.	Eq. (1)	Eq. (2)
30				0·42	0·3	0·4
60				4·4	2·5	3·5
90				15·4	8	11·5
100	20·8	4·5	45	23	11	15
120				37	18	25
150	75	15	155	69	35	45
200	176	35	375	154	75	100
225				195	100	140
250	340	70	730	207	125	165
275				207	150	200
300	564	125	1,260	142	180	220
400	1,390	295	2,950			

Tables 1 and 2 show some experimental sensitivity values, obtained with a four-wire thermal conductivity detector (wire thickness 0·003 cm.; wire length 12 cm.; wire resistance at 0° C. 16·3 ohm; temperature coefficient of the platinum wires 0·0037; detector temperature 25° C.).

The sensitivities (E/x) are expressed in mV. per volume fraction of the vapour. In addition to the experimental values, sensitivities were calculated using equations 1 and 2. A direct comparison between the experimental and calculated values can be made when $\mathrm{d}t/\mathrm{d}x$ is converted into $\mathrm{d}E/\mathrm{d}x$ by means of an approximate equation for the out-of-balance voltage of the bridge,

$$\mathrm{d}E/\mathrm{d}x = \tfrac{1}{2}\, i\, R_0 \alpha\, \mathrm{d}t/\mathrm{d}x \text{ (ref. 7)}$$

where i is the total bridge current, R_0 the resistance of the filaments at 0° C. and α the temperature coefficient of these resistances.

Up to a total bridge current of 250–300 m.amp. (the current should not exceed this figure when nitrogen is used as a carrier gas), the system methane – nitrogen gives higher sensitivities than the system methane – hydrogen, while for propane higher sensitivities are obtained when hydrogen is used as a carrier gas. It is interesting to note that for the propane – nitrogen system the sensitivity reaches a maximum at a current of about 250 m.amp.

The agreement between the experimental values and the sensitivities calculated with both (1) and (2) is rather poor. In our opinion this clearly illustrates the difficulty of predicting sensitivities from k_1 and k_2 without knowing the exact value of the thermal conductivity of the mixture. Although in most cases a calculation of sensitivities will be impossible, our experiments confirm the view[2-6] that the highest sensitivity values can be obtained by employing a carrier gas of high thermal conductivity.

Note added in proof. A. B. Littlewood, in a recent communication (*Nature*, 184, 1631; 1959), gives a semi-empirical method of calculating sensitivities from molecular dimensions.

METALLURGY

Reaction between Copper and Solid Oxygen condensed at Very Low Temperatures from a Gas Discharge

IN recent years numerous studies[1] have been carried out on the short-lived reactive species formed in an electric discharge after trapping and storing them on a low-temperature surface. This communication is concerned with the interaction between the discharge products of oxygen and the metal surface upon which they have been trapped at a low temperature. Copper was chosen as the metal to study because it is frequently used as a condensing surface. Also some data are available on the low-temperature (77° K.) oxidation of copper by molecular oxygen[2,3] and on the reaction of oxygen discharge products with copper at elevated temperatures[4].

Both single crystal and polycrystalline specimens of 99·99 per cent copper were studied. Their surfaces were specially prepared so that they were clean,

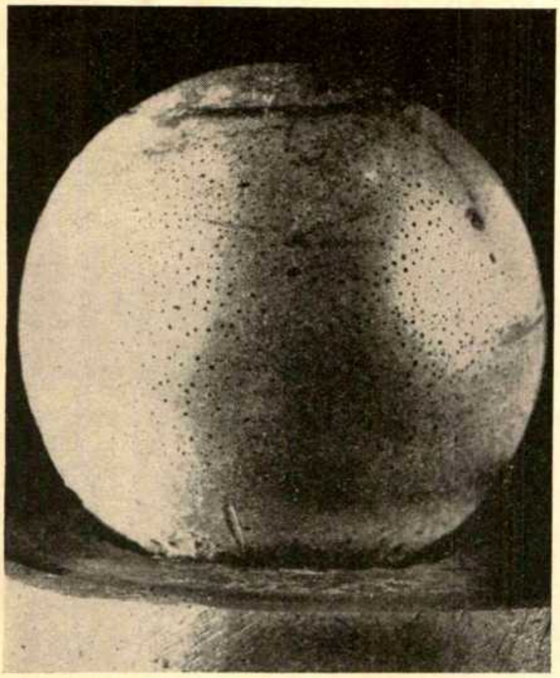

Fig. 1

strain-free, and smooth[5]. Some preliminary experiments were carried out in which a single-crystal sphere at 4·2° K. was placed in the path of a stream of ordinary tank oxygen which had been passed through a 2,450-Mc. electrodeless discharge to dissociate it partially. Small specks of a reaction product could be detected visually (Fig. 1). These were later identified as cupric nitrate by X-ray diffraction, indicating that the tank oxygen contained small amounts of nitrogen. The random distribution of the reaction product on the surface of the spherical single crystal rules out orientation effects. When oxygen of 99·998 per cent purity was used, no reaction could be detected visually.

Most of the experiments were carried out in an apparatus in which the copper specimen, after annealing in hydrogen at 450° C., could be cooled to a desired temperature (usually 4·2° K.) and the thickness of films formed on its surface measured using an ellipsometer[6].

Oxygen was deposited on the bare metal surface, and the thickness of the gas film was measured with the ellipsometer. When discharge products were desired, the oxygen stream was first passed through the microwave generator wave-guide before impinging on the metal surface. After warm-up of the copper specimen to room temperature, ellipsometer readings were again taken.

It was found that, under these particular experimental conditions (Dewar pressure during deposition, about 2×10^{-5} mm. mercury; inlet pressure of oxygen, 0·15–0·7 mm. mercury), molecular oxygen had no effect at any temperature up to 300° K. When the pure oxygen was passed through the microwave discharge, however, a film of reaction product of about 20 Å. thickness formed if the copper surface was at 4·2° K. during deposition. The films formed on all surfaces studied ({100}, {110}, and {111}) were of the same thickness, and this thickness was not increased by subsequent runs. Deposition of extraneous material was ruled out by the fact that no film was found on warm-up on an adjacent gold surface employed as a control. The discharged oxygen had no effect on copper at 40° K. or higher. Further, if a thin film (400 Å.) of molecular oxygen was placed on the copper surface at 4·2° K. and discharged oxygen condensed on top of this, no reaction was observed. Finally, since ozone is formed as one of the discharge products, a check was made to see if it was responsible for the reaction observed by depositing pure ozone on the copper at 4·2° K. As with molecular oxygen, no reaction was observed.

It appeared, then, that a reaction took place on the surface between 4° K. and 40° K., forming a product that is solid at room temperature. The species responsible for the reaction observed is probably atomic oxygen, and the reaction product, an oxide.

The concentration of the trapped oxygen atoms is very low, probably of the order of tenths of a mole per cent[7]. Most of these would recombine at a temperature between 4·2° and 40° K., where they have sufficient mobility, rather than react with the metal surface. The formation of an oxide film may be due to a reaction between the condensed molecular oxygen and the copper surface. The activation energy for this reaction could be provided by the local heating produced by recombinations of oxygen atoms. Further work is in progress on the system described here and on other metals and gases.

We wish to acknowledge the assistance of Dr. G. J. Minkoff of the Imperial College of Science and Technology, London, in carrying out the preliminary experiments while a guest worker at the National Bureau of Standards.

This work was carried out under the National Bureau of Standards Free Radical Research Program, supported by the Department of the Army.

ENGINEERING

High-Temperature Creep of Graphite

Davidson and Losty[1] have proposed a logarithmic equation to describe the creep behaviour of synthetic graphites in the temperature-range 1,300–2,000° C. Analysis of results obtained at this laboratory by Martens, Jaffe and Button[2,3] indicates that this equation also gives a good description of graphite creep at higher temperatures, up to 3,000° C. However, there are appreciable differences in the relation of creep to temperature and stress in the two temperature ranges.

Short-time tensile creep data in the temperature-range 2,400–3,000° C. have been obtained for several commercial grades of synthetic graphite using test specimens with a 0·25-in. diameter by 1-in. long gauge section. Heating was accomplished in an automatically controlled graphite tube furnace in a helium

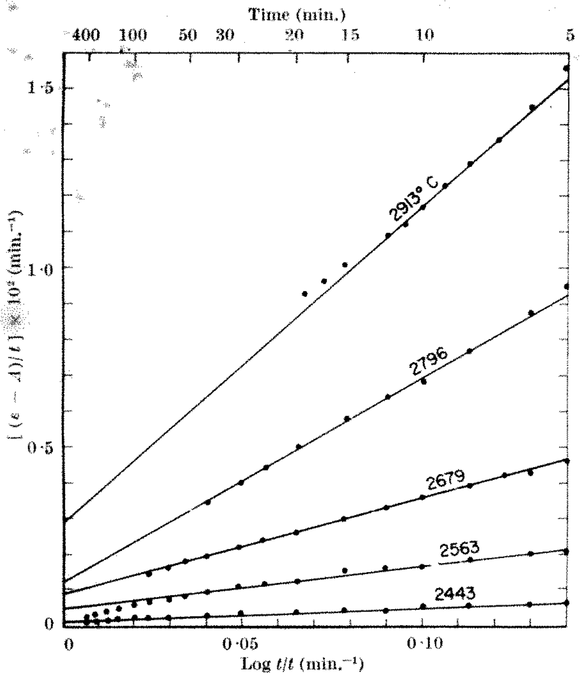

Fig. 1. Creep of *H3LM* graphite plotted according to equation 1. Stress 2,000ψ, parallel to the grain

atmosphere. Tests were generally run to fracture, or 400 min., whichever occurred first. The results discussed here were obtained on specimens cut from one block each of Great Lakes Carbon Co. *H3LM* and Speer Carbon Co. 3499. (The data analysed here were obtained from blocks designated 0401 and 0106 in refs. 2 and 3.) All tests were made on specimens as machined without any preliminary heat treatment, unless otherwise noted. Further details of the creep measurement techniques have been described elsewhere[2,3].

The equation found by Davidson and Losty is of the form:

$$\varepsilon = A + B \log t + Ct \qquad (1)$$

Here, ε is the creep strain, t is time, and A, B and C are constants for each test. Some representative results, plotted on co-ordinates which give a straight line if equation 1 is obeyed, are shown in Fig. 1. The results plotted are for times greater than 5 min. It is evident that the fit is quite good. The points tend to fall above the best straight line at short times and below it at long times. The short-time deviations, which were observed in all the results, may arise in part from errors in the estimation of the A values and from strain measurement errors. The deviations from linearity at long times (for example, the 2,563° C. curve, Fig. 1) cannot be ascribed to these errors. Steady-state creep-rates (C values) determined from the final portion of the creep curves agree with those determined by drawing a tangent to the elongation versus time curve, whereas rates obtained from a linear fit to the early part of the curve (as in Fig. 1) are higher. This behaviour was characteristic of the *H3LM* graphite, but was not generally observed in the 3499 material. This phenomenon apparently reflects a change in the condition of the material which is brought about by the creep deformation. The nature of this change is not understood.

The constants B and C were both found to be Arrhenius functions of the temperature:

$$B = B_0 \exp(-\Delta H_B/RT) \qquad (2a)$$

$$C = C_0 \exp(-\Delta H_C/RT) \qquad (2b)$$

where B_0 and C_0 are functions of the applied stress, R is the gas constant, T is the absolute temperature, and ΔH_B and ΔH_C are observed activation energies. This agrees with the results of Davidson and Losty. The activation energies obtained here for B and C, in that order, were: 112 and 106 kcal./mole from the initial portion of the creep curve, *H3LM*; 70 and 180 kcal./mole for the final part of the curve, *H3LM*; and 81 and 204 kcal./mole for 3499. These values are appreciably higher than those obtained by Davidson and Losty (20–50 kcal./mole). Recent experiments have indicated that, for some blocks of commercial graphite, the creep behaviour is altered by heat treatment at 2,800° C. prior to testing at lower temperatures. Therefore, the energy-values obtained here are best regarded as apparent activation energies. Preliminary results indicate that equation 1 still holds following heat treatment, but the observed activation energies are somewhat lower for some blocks. Both B and C were found to be approximately proportional to the square of the initial applied creep stress over the range 600–3,100ψ at 2,565° C. This differs from the results of Davidson and Losty, who found a linear dependence on stress in the 1,300–2,000° C. range.

Some observations were also made on the creep recovery phenomena. In these experiments, the load was removed after a total creep strain of 5–20 per cent and the strain recovery observed at the same temperature as the creep. In some cases the temperature was increased for periods of ½–1 hr. during recovery. This accelerated the rate of recovery but did not increase significantly the total amount of recovered strain. The amount of recoverable strain ranged from one-tenth to one-third of the total creep elongation. For both the as-received and the pre-annealed specimens, the recoverable strain was generally less than one-half of the transient creep strain (the $B \log t$ term in equation 1). This contrasts with the results of Davidson and Losty, who found that the transient creep strain was completely recoverable. The larger total creep strains employed in the present investigation may contribute to this difference in behaviour.

A sigmoidal curve is obtained when the strain recovery is plotted against the logarithm of the time after removal of the load. A description in terms of a superposition of relaxation processes with a broad spectrum of relaxation times is indicated to account for the curvature in this plot at very short and very long times. However, the recovery behaviour can be approximated by a linear logarithmic time dependence, consistent with the use of equation 1 to describe the creep behaviour. Such a description deviates significantly from the observed results only at very short and very long times (for example, < 2 min. and > 200 min. at 2,680° C.).

Equation 1 is compared with two other creep equations, applied to the analysis of high-temperature creep of graphite, in a paper published elsewhere[3].

Grateful acknowledgment is made to L. D. Jaffe and H. E. Martens for helpful discussions and to King Titus for assistance with the computations.

CRYSTALLOGRAPHY

Mosaic Texture of Graphites

Crystal sizes in graphitic carbons are commonly in the μ or sub-μ range. The average dimensions of the crystallites (that is, the parallel-layer groups of condensed aromatic ring networks) in any particular material are usually deduced from measurements of the widths of X-ray powder diffraction maxima. Although the measurements are complicated by the presence of stacking disorders, techniques exist[1] for eliminating the effects due to these. The dimensions thus obtained are: *La* the average diameter of layer-network over which there is considerable perfection, *t* the average height of parallel-layer group over which the stacking is fully ordered, *Lc* the total height of the group irrespective of the presence of disordered (turbostratic) stacking. With crystallite dimensions greater than about 200 Å. the accuracy of the determination depends very considerably, and to an extent increasing rapidly with crystal size, on the corrections for extraneous (instrumental, absorption, etc.) line-broadening effects. Nevertheless, for good natural graphites the crystallite dimensions are consistently found to be not more than a few thousand Å. (ref. 2 and Steward, E. G., and Cook, B. P., unpublished work). For artificial graphites the dimensions are usually less than 1000 Å. (refs. 2,3,4 and Steward, E. G., and Cook, B. P., unpublished work).

Recent considerations[5] of the graphitization process in anthracites, pyrolytic and evaporated carbons suggest that current views on graphitization are unnecessarily restricted by attaching too great an ultimate and exclusive importance to dimensions measured in the above manner: the concept of larger mosaic '*M*' units has been suggested. Kuroda[6] has used electron diffraction to study cokes and has recently reported evidence of the presence of substructure with preferred orientation. Further evidence in support of the general concept could also be deduced from the more recent electron microscope studies by Dawson and Follett[7], who have reported crystal layer-sizes of about 3000 Å. in a graphitized coke for which X-ray diffraction had given *La* values of less than 800 Å.

Visual examination of crystal flakes of natural graphites clearly reveals a highly oriented mosaic structure. Such flakes may have dimensions of several mm., but X-ray diffraction measurement would indicate parallel-layer group dimensions much smaller than this. That the '*L*' dimensions deduced from the X-ray diffraction broadening arise from the sub-structure may be demonstrated quite simply by the X-ray diffraction Laue method. Fig. 1*a* shows a Laue pattern taken with an X-ray beam of 50μ diameter, approximately normal to a flake selected from a sample of natural graphite. The pattern is seen to approximate to that of a single crystal. However, the spots show break-up typical of a mosaic crystal and it is the diffraction broadening of the individual reflexions within the spot-clusters which is dependent on the size of the mosaic sub-blocks (that is, the parallel-layer groups) and which is the diffraction broadening normally recorded in the 'powder method'. The well-modulated *10* reflexions and the sixfold symmetry of these indicate that there is little stacking disorder of layer-planes within the parallel-layer groups and that there is strong preferred orientation of the *a*-axes of the various parallel-layer groups comprising the mosaic: the weak intensity of *0002* reflexions indicates that the layer-planes are essentially perpendicular to the X-ray beam.

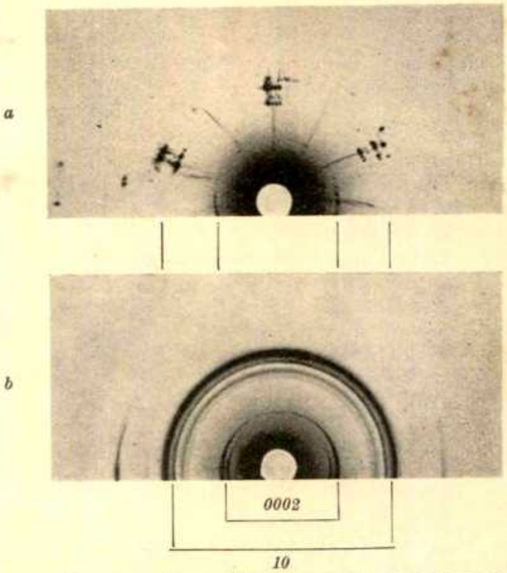

Fig. 1. Laue-type X-ray diffraction photographs of graphitic carbon flakes: 50μ beam approximately normal to flakes. (Copper radiation.) *a*, Natural (Ceylon) graphite; *b*, petroleum coke: graphitized at 2,700° C.

It is logical that a similar mosaic condition exists to different extents in graphitic carbons generally. This is illustrated in Fig. 1*b*, which shows the Laue pattern obtained with the 50μ beam, from a thin flake of graphitized coke: the selected flake was not necessarily typical of the whole coke. The intensity of the *0002* reflexion relative to that of the *10* reflexions again indicates a mosaic formed by strong preferred coplanar orientation, parallel to the surface of the flake, of the *La* areas: the pronounced arcing of the weak *0002* reflexions is due to the flake being somewhat cylindrically curved about an axis approximately normal to the beam. The extensive modulation of the *10* band into the component 3-dimensional $10\bar{1}0$ and $10\bar{1}1$ reflexions shows that turbostratic stacking is not appreciable: the circumferential arcing of spots to form smooth rings is therefore indicative of a large number of small (*La*) units and of lack of preferred orientation of the *a*-axes of these within the above mosaic planes.

These simple experiments thus demonstrate by X-ray diffraction methods the existence one would expect of mosaic units in graphitic carbons. In such a material the particles will not necessarily have a uniform *L* : *M* size relationship and there will also be different types of boundary between the L volumes comprising an M mosaic. In some circumstances there may be a condition where $L = M$ and the particle would then be an unoriented agglomerate of crystallites.

The texture will, of course, vary profoundly from one carbon to another. In a well-crystallized (for example, natural) graphite there will be considerable 3-dimensional near-parallel alignment of layer-groups to form mosaics closely approximating to single crystals. Larger misorientations between the mosaic sub-blocks, particularly in the Ma plane, would in part account for the limited ultimate crystalline development in other so-called 'graphites'.

Thus, while X-ray diffraction has the unique ability to reveal the size of the basic crystalline unit in carbons, further parameters need to be recognized when assessing the general crystalline texture of such materials and when considering their physical properties.

Crystal Structure of Adenosine-5′-phosphate

Adenylic acid, or adenosine-5′-phosphate, is a nucleotide of particular biochemical interest. It is not only a component of ribonucleic acid, but also forms a part of the structure of many coenzymes and, as the di- and tri-phosphate, it is frequently involved in metabolic processes. Spencer[1] has reviewed the information at present available on the constituent components of the nucleotides from crystal structure analysis. In addition to the references cited by Spencer, one may also mention the brief note of Brown *et al.*[2] on a single projection of adenosine-3′-phosphate and the paper by Alver and Furberg[3] on the structure of cytidine-3′-phosphate. No nucleoside-5′-phosphate has been solved previously.

The unit cell parameters for adenylic acid are $a = 12{\cdot}77$ Å., $b = 11{\cdot}82$ Å., $c = 4{\cdot}88$ Å., $\beta = 92°\ 19'$, space group $P2_1$. Unidimensionally integrated data were collected on a Wiebenga-type camera using copper radiation.

The structure was solved by three-dimensional Patterson superposition methods based on identification of the phosphorus peak in the Harker section at $v = \frac{1}{2}$. It has been refined in projection on (010) and along [001] to R values of 13·7 per cent and 13·4 per cent respectively. Fig. 1*A* is an F_0 synthesis showing $e(x,y)$ at the present state of refinement, and Fig. 1*B* is a perspective drawing of the molecule.

It may be noted here that the ribose ring is puckered in such a way that carbon 3′ is about 0·5 Å. out of the approximate plane formed by the four remaining atoms of the ring, lending further support to Spencer's hypothesis that the preferred conformations of the ribose ring are those with either atom 2′ or 3′ out of the plane.

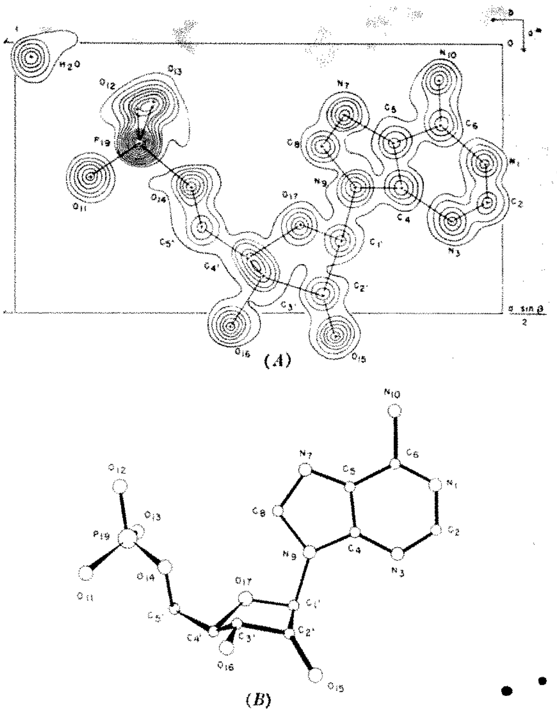

Fig. 1. (*A*) Fourier synthesis showing projection of electron density along [001]; contours at intervals of 2 e/Å.². (*B*) Perspective drawing of the adenylic acid molecule

The structure is being refined further with full three-dimensional data, and a complete account will appear elsewhere.

Crystal Structure of Tetraphenyl*cyclo*butadiene Iron Tricarbonyl

There has been much recent interest[1-5] in the possible existence of the *cyclo*butadiene ring system in transition metal complexes, and a crystal structure determination[6] has verified that Criegee and Schröder's $C_8H_{12}NiCl_2$ is indeed tetramethyl *cyclo*butadiene nickel dichloride. The present investigation similarly verifies the conjecture[4,5,7] that the compound $Fe(CO)_3(C_6H_5C_2C_6H_5)_2$ of Hübel *et al.*[4] is tetraphenyl*cyclo*butadiene iron tricarbonyl.

The yellow crystals, supplied by European Research Associates, are monoclinic with $a_0 = 8{\cdot}93$ Å., $b_0 = 18{\cdot}73$ Å., $c_0 = 14{\cdot}10$ Å., $\beta = 92{\cdot}6°$, with four molecules per cell, and have extinctions corresponding to space group $P2_{1/c}$. Diffraction intensities were obtained by the stationary crystal–stationary counter technique[8] at rates as high as 500 a day using a General Electric *XRD*-5 spectrometer equipped with single-crystal orienter and scintillation counter. A total of 2,306 reflexions, all the reflexions with $\lambda^{-1} \sin\theta \leqslant 0{\cdot}481$, were measured with a molybdenum $K\alpha$ source; of these, the strongest 1,100 have been used in the work so far.

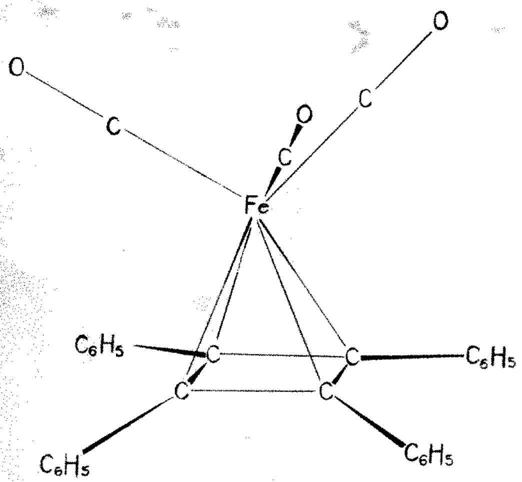

Fig. 1

The three-dimensional Patterson function clearly indicated the correct Fe—Fe vectors. Three-dimensional superposition based on the Fe position and recorded by means of the zero contour of the minimum function led to the correct structure except for two carbon atoms, one missing and one badly misplaced. An electron-density map then revealed the complete structure, and two further cycles of Fourier refinement have resulted in only relatively small further adjustments. The present agreement between observed and calculated structure factors is good, with discrepancy index (for the 1,100 reflexions used) of $R = 0 \cdot 145$. Further refinement is in progress.

The molecular structure is shown in Fig. 1. The *cyclo*butadiene ring is square planar to within the errors of the present determination of atomic positions, which, from the planarity and symmetry of the phenyl rings, linearity of the Fe—CO groups, and approximate agreement of the bond-lengths with standard values, are judged to be about 0·1 Å. Relative to an axis through the iron atom and the centroid, x, of the $(C_6H_5)_4C_4$ group, the $(CO)_3$ constellation has three-fold symmetry to within about 3° (with angles x-Fe—CO of about 120°) and the $(C_6H_5)_4$ constellation has fourfold symmetry to less than 5° except for twisting and bending of the phenyls out of the mean C_4 plane. The twists, all of the same hand in any one molecule, are about 30°, 30°, 30°, and 60°, and the bends, all away from the $Fe(CO)_3$, average about 10°. The phenyl of 60° twist is *trans* to a carbonyl. The intermolecular packing is generally good, but whereas no consistent intramolecular explanation is apparent for the asymmetry of phenyl twist, this irregularity does seem to correspond to certain irregularities in the packing.

CHEMISTRY

Gaussian Wave Functions for the Hydrogen Molecule

Some time ago, Boys[1] showed that the troublesome potential energy integrals which arise in the quantum mechanical treatment of molecular problems are easily evaluated when the electronic wave function is expressed in terms of Gaussian functions:

$$\psi = \sum_k C_k \exp\left\{ - \sum_j a_j^k \mid r_j - \alpha_j \mid^2 \right\} \qquad (1)$$

(C_k, a_j^k are constants, α_j^k are constant vectors and r_j is the position vector of the j^{th} electron), and in terms of derivatives of such functions. The most complicated integrals can be reduced to expressions containing elementary functions and error functions (or derivatives of error functions).

Recently, Boys[2] showed that this is also true when correlation terms such as $\sum_j \sum_i g_{ji}^k \mid r_j - r_i \mid^2$ are added to the exponent of (1); while one of us[3] found independently that the potential energy integrals associated with Gaussian functions of the very general type:

$$\psi = \sum_k P_k \exp\ (- Q_k) \qquad (2)$$

(where Q_k is any positive definite quadratic form and P_k a polynomial in the electron co-ordinates) can be reduced to quadratures.

Gaussian functions of the form (1) have been used by Meckler[4] in calculations for the oxygen molecule. The more general functions which result from the addition of correlation terms are of interest because inter-electronic correlation is not easily taken into account when conventional wave functions (based on atomic orbitals) are used.

As a first step in the examination of wave functions of the form (2) we have carried out calculations for the ground-state of the hydrogen molecule. The wave functions were of the form:

$$\psi = \sum_{k=1}^{n} C_k \left[\varphi_k^+ (1,2) + \varphi_k^+ (2,1) + \varphi_k^- (1,2) + \varphi_k^- (2,1)\right]$$

$$\varphi_k^\pm = \exp\{-a_k (x_1^2 + y_1^2) - b_k (x_2^2 + y_2^2) - 2g_k (x_1x_2 + y_1y_2) - c_k (z_1 \pm \alpha_k)^2 - d_k (z_2 \pm \beta_k)^2 - 2h_k (z_1 \pm \alpha_k) (z_2 \pm \beta_k)\} \qquad (3)$$

which corresponds to electron orbitals of cylindrical symmetry with correlation and with 'floating' centres. The energy was minimized with respect to the parameters $C_k, a_k, b_k, c_k, d_k, \alpha_k, \beta_k, g_k, h_k$ at the equilibrium internuclear distance. Table 1 lists the binding energies obtained for $n = 3$, 4, 6 and 8.

Table 1

$n =$	3	4	6	8
No. of independent variable parameters	26	35	53	71
D (eV.)	4·30	4·42	4·52	4·58

The omission of the correlation parameters (g_k, h_k) led to poorer results (4·07 for $n = 3$ and 4·35 for $n = 8$).

The binding energies obtained with $n = 6$ and $n = 8$ are, so far as we know, higher than any other calculated values except those of James and Coolidge[5] (4·70); and it is worth noting that these authors used elliptical co-ordinates which are not suitable when the molecule contains more than two centres.

In spite of the large number of variable parameters the computing times (on a 'Mercury' electronic computer) were relatively short: the evaluation of a typical matrix element, for example:

$$\int \varphi_{k^+}(1, 2)\, H\varphi_{k^-}(2, 1)\, d\tau$$

required less than 0·2 sec., the calculation of the energy for a given set of parameters varied from 13 sec. for $n = 3$ to 63 sec. for $n = 8$, and the corresponding total computing times were approximately 2 hr. and 14 hr. respectively.

A full account will be published elsewhere. Further work is in progress.

We wish to express our thanks to the director and staff of the London University Computer Unit for enabling us to use the facilities of the Unit.

Non-Equilibrium Theory of Gas-Liquid Chromatography

In a gas-liquid chromatographic column the assumption of equilibrium demands that the rate constants for solute transfer between the gas and the liquid phases must be infinitely large and the flow-rates extremely small. In practical columns neither of these conditions is ever fulfilled; the kinetic rate constants are finite, and the use of extremely slow flow-rates is out of the question because of undesirably long retention times and pronounced longitudinal diffusion in the gas phase which enhances band broadening. This has led various workers to advance theories which take account of the effect of non-equilibrium conditions on band structure and column efficiencies[1–4]. Of particular importance is the van Deemter theory[4], which uses the driving force concept to describe the departure from equilibrium in terms of resistances to mass transfer in the gas and the liquid phases. The hypothesis of interfacial equilibrium involved in the theory is one the validity of which cannot be demonstrated directly by experiment. The existence of equilibrium at the interface would mean that if the concentration in the liquid phase at the interface is specified, the concentration in the gas phase at the interface is the same as if the two phases had been in contact for an indefinite length of time. Owing to continuous flow of carrier gas it is scarcely likely that the molecules once evaporated from the surface will get to the same spot again, and this, obviously, introduces conceptual difficulties regarding the nature of dynamic equilibrium at any point within the column. A natural consequence of the assumption of interfacial equilibrium is that once the diffusing molecules strike the interface, they pass into the other phase without experiencing any resistance at the interface itself. On the contrary, discrepancies between the calculated and observed rates of absorption suggest that there should be resistance to mass transfer at the interface[5–7]. From the point of view of the theory of absolute reaction-rates, there are sound theoretical grounds for postulating the existence of interfacial resistance. One can imagine an energy barrier which may involve the formation of an 'intermediate-activated state'; of all the molecules which strike the boundary surface only those which have the required energy of activation for diffusion surmount the energy barrier while the rest rebound into the gas phase, and furthermore the orientation of molecules may play a part.

A more general theory of the chromatographic process, which takes into account the whole gamut of diffusion processes and is not restricted to equilibrium conditions, has been worked out. The absorption and desorption processes are described by the simple laws of kinetic theory which can handle problems outside the domain of equilibrium in a fairly direct manner. The solution of the partial differential equations, when interpreted in terms of the first and second moments of the residence-time distribution-functions, leads to the following expressions for the retention time (t_R) and the height equivalent to a theoretical plate (H):

$$t_R = \frac{L}{u}\left(1 + \frac{a_2}{a_1}\frac{k_1}{k_2}\right) \qquad (1)$$

and:

$$\overbrace{H = \underbrace{\underbrace{2\lambda dp}_{\text{Apparent diffusion}} + \underbrace{2\gamma\,\frac{D_1}{u}}_{\text{Molecular diffusion}}}_{\text{Longitudinal diffusion}} + \underbrace{\frac{2}{3}\,\frac{\frac{a_2}{a_1}\cdot\frac{k_1}{k_2}\cdot d^2_{f_1}}{\left(1+\frac{a_2 k_1}{a_1 k_2}\right)^2}\cdot\frac{u}{D_1}}_{\text{Resistance to mass transfer}}}^{\text{GAS PHASE}} + \overbrace{2\,\frac{\frac{a_2}{a_1}\left(\frac{k_1}{k_2}\right)^2}{\left(1+\frac{a_2 k_1}{a_1 k_2}\right)^2}\,\frac{a_2}{k_1\sigma}\cdot u}^{\text{Interfacial resistance to mass transfer}} + \overbrace{\underbrace{\frac{2}{3}\,\frac{\frac{a_2 k_1}{a_1 k_2}\cdot d^2_{f_2}}{\left(1+\frac{a_2 k_1}{a_1 k_2}\right)^2}\cdot\frac{u}{D_2}}_{\text{Resistance to mass transfer}} + \underbrace{2\,\frac{a_2 k_1}{a_1 k_2}\cdot\frac{D_2}{u}}_{\text{Longitudinal diffusion}}}^{\text{LIQUID PHASE}} \qquad (2)$$

where a_2/a_1 is the ratio of the area of cross-section of the liquid to that of gas phase, d_{f_1} and d_{f_2} are the 'effective depths' of the gas and liquid phases, k_1 and k_2 are absorption and desorption-rate constants respectively, σ the surface area per unit column length, and the rest of the letters have the same meaning as described in van Deemter's theory.

The theoretical basis for the above expressions is too lengthy to be given here. Although diffusion in the liquid phase normal to the interface is of primary importance, the general treatment of the problem demanded the inclusion of diffusion parallel to the interface which is represented by the last term in equation 2. In gas-liquid chromatography, the resistance to mass transfer in the gas phase is usually assumed to be negligible as compared with that in the liquid phase. The resistance at the interface may be an important factor in the design of chromatographic columns particularly at high flow-rates and low specific surface areas. We are at present investigating the possibility of evaluating the expression for interfacial resistance.

I wish to express my thanks to the Directors of "Shell" Research, Limited, for their kind permission to publish this communication. I am also grateful to Mr. A. J. Davies for many helpful discussions.

A Rapid Method for Qualitative Analysis of Volatile Mercaptan Mixtures

THE recently developed technique of flash exchange gas chromatography[1,2] has proved valuable for the determination of trace quantities of volatile aldehydes, ketones and acids. This approach has now been extended to the qualitative analysis of volatile mercaptans[3,4] by use of the exchange reaction between mercuric mercaptides and toluene-3,4-dithiol.

Mercuric mercaptides[5–7] (3–5 mgm.) are introduced into a glass capillary melting point tube and an equal weight of warmed (liquid) toluene-3,4-dithiol added. The tube contents are centrifuged to produce a slurry of mercaptides in toluene-3,4-dithiol. The open end of the tube is placed in the sample port of a gas chromatography unit and the lower part of the tube is heated at 245–260° for 15 sec. in an oil-bath. The exchange reaction takes place and C_1–C_4 saturated mercaptans flash into the unit for separation and identification.

In Table 1 are tabulated the retention times for mercaptans regenerated in the exchange reaction. The reaction is slow and only the highly volatile mercaptans escape the reaction mixture in sufficient amount to give good detector response (heating *n*-pentyl and *n*-hexyl mercaptides with toluene-3,4-dithiol produces no definite peaks).

Table 1. RETENTION TIMES FOR MERCAPTANS (*R*SH) REGENERATED FROM MERCURIC MERCAPTIDES WITH TOLUENE-3,4-DITHIOL

R	Retention time (min.) ¼ in. × 10 ft. Carbowax 1540, 80° *	Retention time (min.) ¼ in. × 5 ft. Apiezon *M*, 60° †

iso-C_3H_7	5·1	3·3
n-C_3H_7	7·9	5·4
iso-C_4H_9	10·5	9·4
sec.-C_4H_9	8·6	8·4
tert.-C_4H_9	5·2	4·3
n-C_4H_9	13·9	12·9

* Flow-rate of helium, 35 ml./min. † Flow-rate of helium, 50 ml./min.

No evidence was found for the thermal decomposition of mercuric mercaptides to disulphides[7] under the conditions of the exchange reaction. Alkyl sulphide–mercuric chloride complexes react with toluene-3,4-dithiol to produce the sulphide along with small amounts of the corresponding mercaptans. Lead mercaptides give a much slower rate of reaction with toluene-3,4-dithiol than the mercuric mercaptides.

We wish to acknowledge the helpful interest of Prof. Arthur Furst (Stanford University) in providing several potential exchange reagents.

Coloured Sulphur Deposits at Low Temperatures

F. O. RICE obtained green, purple and black deposits by chilling sulphur vapour at liquid-air temperature[1]. Several parameters of the experiments, predominantly the vapour temperature, determine the colour. With the help of equilibrium data of the vapour composition[2] Rice has concluded that the yellow deposits arise from cyclo-S_8, green ones from catena-S_8 and purple to black ones from S_2.

In the course of a series of investigations on unstable low-temperature deposits we have chosen the sulphur system as a model. A summary of our results follows[3].

Each apparatus consisted of four units in series: (1) sulphur reservoir with large liquid surface at temperature ν_S° C.; (2) heated quartz-tube designed for multiple collisions of sulphur molecules with the wall at ν_f° C.; (3) molecular beam defining orifice;

Table 1

ν_s ° C.	ν_f ° C.	ν_t ° C.	mgm. S/cm.² min.	Colour of deposit approximately 10μ thick Reflected light	Transmitted light
160	200	−188	0·3	yellowish-green	
160	275	−188	0·3	dark green	red brown
160	300	−188	0·3	blue green	red
160	380	−188	0·3	violet	yellow red
105	600	−188	0·01	green	reddish
145	600	−188	0·2	dark green	red
200	600	−188	1·6	violet	yellow red

(4) target (ice, sodium chloride, potassium bromide, quartz, aluminium, copper) in high vacuum at temperature ν_t° C. The experiments were performed under near equilibrium and widely varied conditions, for example, ν_s and sulphur vapour pressure, ν_f, ν_t, (liquid helium, hydrogen, air, ethylene, solid carbon dioxide, room temperature), residual gas-pressure, rate of sulphur deposition.

Coloured deposits (other than yellow ones) are formed at $\nu_f > 250°$ C., $\nu_t < -100°$ C., and at a target ambient pressure sufficiently low for essentially collision-free flow of molecules from orifice to target. The deposits have a rough surface and sandy texture below − 100° C.

Table 1 shows the correlation of colour with ν_f and rate of deposition.

Ultra-violet and visible spectra of green deposits are continuous with a maximum absorption at 507 mμ.

In the infra-red all the deposits lower the transmission considerably in the range 1–25μ, probably due to scattering. Coloured deposits exhibit a strong absorption-band at 14·96μ = 668·5 cm.$^{-1}$ (Fig. 1*a*) with a half-width of ∼ 7 cm.$^{-1}$. This band grows linearly with deposit thickness (Fig. 1*b*), does not change in 150 hr. at − 190° C., but vanishes according to a first-order rate law with $t_{\frac{1}{2}}$ = 57·7 hr. at − 104° C. (Fig. 1*c*), and (extrapolated) $t_{\frac{1}{2}}$ = 18 min. at −78° C. Deposits which have been above − 78° C. do not redevelop infra-red absorption or colour on re-freezing to − 190° C.

This infra-red band is without any doubt due to the unstable sulphur form (method of purification and other arguments[3]). There is no measurable qualitative correlation of infra-red spectrum with colour. In matrix experiments with xenon (Xe : S = 500) only green deposits are formed with the same band at 668 cm.$^{-1}$.

At a micro-wave frequency of 9,500 Mc./sec. no paramagnetic resonance is observed with 3·2 mgm. of green sulphur deposit at − 188° C. in the cavity between 2,000–7,000 gauss (line width 100 gauss). An upper limit of 0·01 per cent detectable 'free spins' relative to the deposited number of S-atoms follows from this observation (measurements by Mr. F. Waldner, Physics Institute of the University of Zurich).

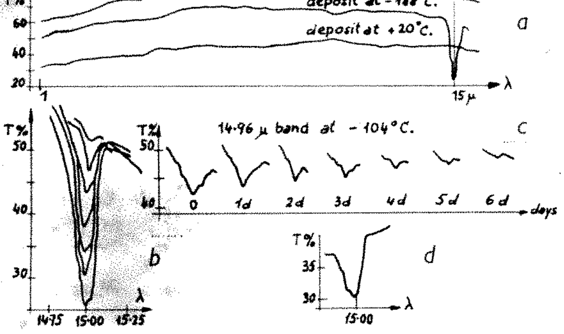

Fig. 1

Deposits of different colour have an electrical resistivity of 2 × 10^6 Ω cm. at − 188° C. compared with 10^{18} Ω cm. for normal sulphur. No photosensitivity with near ultra-violet and visible light is observed.

At room temperature deposits on sodium chloride formed below − 100° C. can be removed as coherent, shiny films which collapse elastically to a fortieth of their surface-area. They are 30 per cent soluble in carbon disulphide 2 hr. after warming up.

The experiments with a xenon matrix demonstrate the existence of trapped S_2, since this is the only sulphur constituent of the molecular beam. The infra-red absorption at 668·5 cm.$^{-1}$ must, therefore, be attributed to an induced vibrational transition of S_2 in the asymmetrical quasi-solid environment which has not been communicated before. There is a shift of 53 cm.$^{-1}$ from the fundamental ω_0 = 721·6 cm.$^{-1}$ in the gaseous state[4]. This fact and a barely visible fine-structure (Fig. 1*d*) are also characteristics of induced absorptions in liquid or solid oxygen[5]. S_2 is also responsible for the green colour of the xenon matrix. With the deposits of pure sulphur alone additional colours and a not very much stronger infra-red band are observed than in the very dilute S_2–Xe matrix. This can be understood by the following argument. S_2 molecules arrive at the target with enough kinetic energy to align themselves, combine, and form unoriented chains of variable length before attaining the target temperature. All these S_n-chains (n = 3, 4 . . . 8 . . .) together essentially show continuous infra-red absorption in the range studied. They form a 'self-matrix' which traps S_2 molecules at a concentration which is dependent on the parameters of deposit-formation, but which is constant under specified conditions.

Whereas this mechanism accounts for the transformation of most of the S_2 molecules on the target, the explanation of the different colours must start from the observation that no direct relation of the molecular composition of the deposits with colour exists. Infra-red absorption attributable to S_3 or S_4 . . . or S_8 . . . is not detected since no band, except at 14·96μ, shows up clearly. Therefore the colour must be due to the physical pattern of aggregation of the sulphur on the target, that is, to selective scattering at polymer-clusters of roughly equal diameter[6]. Their size (∼ 1000 Å.) depends on the rate of deposition or vapour temperature (Table 1). Reflected and transmitted light have complementary colours in agreement with this interpretation. Above − 100° C. the clusters combine and merge into a film covering the target evenly. The rough surface changes to a shiny one. Trapped S_2 molecules are set free to add to longer chains. On freezing again no S_2 absorption or colour-changes are detectable. The result of the paramagnetic resonance measurements is consistent with these interpretations[7]. The biradical character of the chains is probably responsible for a much lower electrical resistivity, the electrons in antibonding π-orbitals being largely delocalized along the chains.

This work has been supported in part by the Schweizerischer Nationalfonds, project *A* 92. We

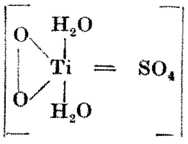
Nature of the Colour-forming Species in Peroxy Titanium Sulphate

Although titanium is determined colorimetrically in aqueous sulphuric acid medium in presence of excess of hydrogen peroxide, the nature of the colour-forming species is not known definitely. Schwarz[1] suggested that the colour was due to the peroxo–disulphato titanate anion $[O_2Ti(SO_4)_2]^{2-}$. On the other hand, Jahr[2] and later Gastinger[3] considered that the colour of the compound was due to the peroxy titanyl cation $[TiO_2\ aq.]^{2+}$, and suggested the following equilibrium in solution:

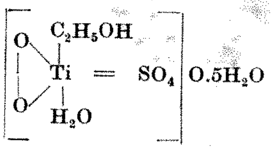
$$\underset{\text{Coloured}}{[TiO_2\ aq.]^{2+}} + H_2O = \underset{\text{Colourless}}{[TiO\ aq.]^{2+}} + H_2O_2 \qquad (1)$$

Schaeppi and Treadwell[4] attributed the colour to O_2TiSO_4 or $[O_2Ti(SO_4)_2]^{2-}$, whereas Babko and Volkova[5] represented the coloured complex ion as $[Ti(H_2O_2)]^{4+}$. Mori, Shibata, Kyuno and Ito[6] regarded the coloured species as $[TiO_2\ aq.]^{2+}$ or $[Ti(OH)_2(H_2O)(H_2O_2)]^{2+}$, assuming the co-ordination number of titanium to be four. Thus, a variety of constitutions has been proposed to explain the colour-forming species of the titanium complex, based on the investigations carried out in dilute sulphuric acid medium, but the complex has not been isolated so far.

We prepared a concentrated solution of peroxy titanium sulphate by the reaction of a freshly prepared titanium hydroxide with a cooled mixture of the calculated quantity of sulphuric acid and excess of hydrogen peroxide. The solution, when evaporated at 25° C. by passing dry air through it, gave a red-coloured solid peroxy complex of the composition $TiO_2SO_4.3H_2O$. The best sample prepared so far was 95 per cent pure, the balance being $TiOSO_4.3H_2O$. The complex contained a true peroxy group as shown by Riesenfeld Liebhasky test. It is amorphous and highly soluble in water and in absolute alcohol, but hydrolyses on dilution with water. The hydrolysis of the compound in aqueous solutions is prevented by dilute sulphuric acid. From various physico-chemical studies the solid compound is assigned the structure (I):



(I)



(II)

The compound in dilute sulphuric acid has an absorption maximum at 410 mμ, as also observed by Reeves and Jonassen[7], while in absolute alcohol it is at about 390 mμ. The compound when dissolved in absolute alcohol is found to have the structure (II). The molecular weight as determined by the cryoscopic method in 1 *N* sulphuric acid gives a value of 178, instead of the theoretically calculated value of 230. This shows a dissociation of the complex in solution to the extent of 28 per cent at about − 2° C. To find out the exact nature of the dissociation of the complex, electromigration, conductivity and spectrophotometric investigations were carried out on the complex. The compound in 2 *N* sulphuric acid medium showed very little electromigration towards the cathode, which is in agreement with the finding of Schaeppi and Treadwell[4]. This indicates that the complex has practically zero charge. This observation was confirmed by a conductivity experiment, from which it was found that the conductivity of a 0·5 *M* solution of peroxy titanium sulphate was practically the same as that of the solvent. Thus the coloured complex is probably dissociated into two neutral molecules:

$$TiO_2SO_4 + H_2O = TiOSO_4 + H_2O_2 \qquad (2)$$

This type of dissociation was confirmed spectrophotometrically by the molar ratio method. It was found that the dissociation of the complex ($0{\cdot}325 \times 10^{-3}\ M$) in 1·6 *N* sulphuric acid, in accordance with equation (2), was 40 per cent, whereas in 6·8 *N* sulphuric acid it was 33 per cent, both at 25° C. All studies show that the coloured compound in dilute sulphuric acid medium dissociates mainly according to equation (2).

The present work does not support the observation of Reeves and Jonassen[7] that the sulphate ligand takes no part in complex formation. Further, there is no evidence so far of the formation of the complex ions suggested by Schwarz[1] and by Babko and Volkova[5].

The coloured complex, represented by the structure (I), satisfies the normal co-ordination number of six for titanium. This is also supported by the fact that the two co-ordinated molecules of water are difficult to remove, when the solid complex is subjected to evacuation for a long time, whereas the third water molecule is more easily removed. The complex gives off ozone and oxygen on keeping, indicating the presence of the strained triangular ring of the peroxy group of the complex. The sulphate group occupying two co-ordination positions[8] in the complex is likely to facilitate its hydrolysis in dilute aqueous solutions, forming mainly hydrated titanium peroxide and sulphuric acid.

We thank Prof. M. R. A. Rao for helpful discussions on the subject.

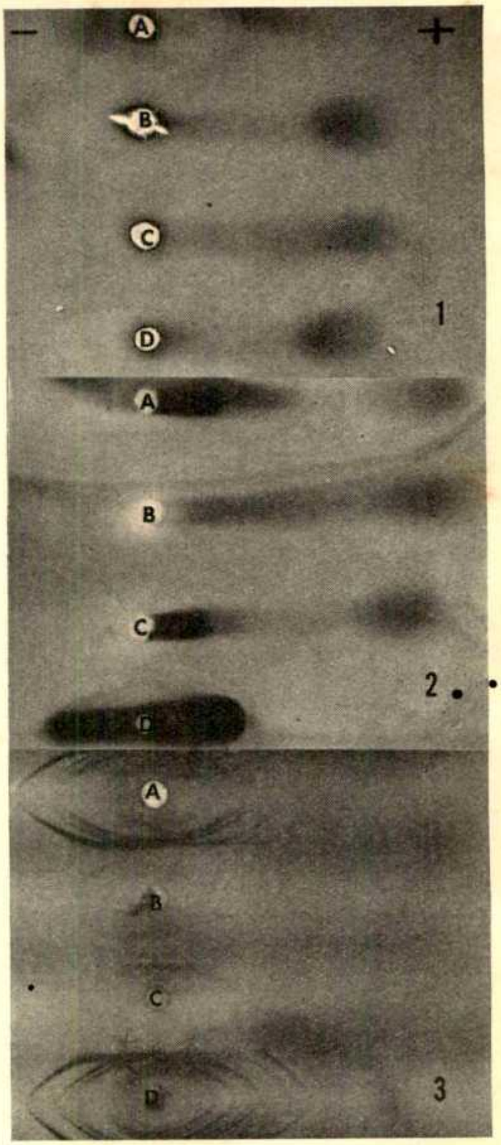
BIOCHEMISTRY

Mucopolysaccharides of Serum and Pleural Fluid

THE use of paper electrophoresis has enabled several investigators to establish the presence of acid mucopolysaccharide components in various tissue extracts[1,2] and urine[3]. Two such substances, staining with toluidine blue, were found in human aortic tissue[4]; concentrated human urine contained three components which stained with alcian blue[5]. The latter all appeared to migrate more rapidly than the albumin fraction, with the fastest component having the same mobility as chondroitin sulphate *A*. In the present work, which is primarily concerned with the electrophoretic characteristics of various body fluids in agar, a component was noted in the perchloric–phosphotungstic acid precipitate of both serum and pleural fluid which possessed staining and electrophoretic properties similar to those of acid mucopolysaccharide in urine.



Figs. 1–3. Electrophoretic properties in agar of serum, pleural fluid and urinary acid mucopolysaccharide. Fig. 1 was stained with alcian blue and azocarmin; Fig. 2 with α-naphthol-phenylenediamine; Fig. 3, immunoelectrophoresis with rabbit anti-human serum placed in troughs adjacent and parallel to the separated fractions. Untreated serum: 1,*A*, 3,*D*; acid precipitated serum: 1,*B*, 2,*A*, 3,*C*; acid precipitated urine: 1,*C*, 2,*B* untreated pleural fluid: 2,*D*, 3,*A*; acid precipitated pleural fluid: 1,*D*, 2,*C*, 3,*B*

The method of Winzler *et al.*[6] was used for the precipitation of mucoproteins from fresh normal human serum, normal urine, and from pleural fluid obtained from a patient ill with cholecystitis. To 2·0 ml. of each specimen was added 8·0 ml. 0·75 *M* perchloric acid. In 10 min. the precipitate which appeared in the serum and pleural fluid was removed by filtration; the urine sample remained clear. 2 ml. of 5 per cent phosphotungstic acid in 2 *N* hydrochloric acid were added to the filtrates and acidified urine, the tubes were centrifuged, the sediments washed twice with the phosphotungstic acid and resuspended in 2·0 ml. veronal buffer, *p*H 8·6, 0·03 ionic strength. Electrophoretic separation was carried out at refrigerator temperature with techniques similar to those described by Zak and Jarkowski[7] and by Crowle[8]. Slides (2 × 3 in.) were coated with 2 per cent 'Ionagar' (Oxo, Ltd., London) and dried at 37° C. Plastic tape was cut into strips approximately 3 mm. wide and layered on the long edges of the slides. Filter paper wicks were placed at each end and 4·0 ml. melted 1 per cent agar in the veronal buffer was poured between the taped edges. A 'Plexiglas' matrix with four holes was lowered until it rested on the tape strips. Following a period of 20 min. in a refrigerator, the agar was removed from the holes by vacuum suction. One 0·01 ml. of each sample was placed in separate holes by capillary pipette. A solution of orange *G* was added to a sixth hole located near an edge of the matrix and close to the cathode-end of the slide. Current (9 V./cm.) was applied until the orange *G* moved 2·0 cm., which required approximately 20 min. The matrix was removed and the slides fixed and stained for mucopolysaccharides[5], lipoprotein or mucoprotein[9] components.

The characteristics of mucopolysaccharide present in perchloric–phosphotungstic acid precipitated serum and pleural fluid were quite similar to those of acid-treated urine as shown in Fig. 1. The substance appeared to migrate 2–3 times faster than the albumin fraction and stained with both alcian blue and α-naphthol-phenylenediamine reagent. The specificity of the former dye for acid mucopolysaccharide was shown by Heremans et al.[5] and the present experiments confirm their observation. The alcian blue stained only the fast-migrating material (Fig. 1) whereas the major substance of the treated serum and pleural fluid appeared to be mucoprotein (Fig. 2), which resembled the immuno-electrophoretic fraction *X* of de Vaux St-Cyr[10]. This was confirmed by extending the period of electrophoresis until the indicator dye had migrated the full length of the slide. The mucoprotein fraction then appeared to have a mobility similar to α_1-globulin of untreated serum. Proteins and lipoproteins were apparently removed by the isolation procedures; only the untreated serum (Fig. 1*A*) and pleural fluid (not shown) counterstained with azocarmin and with oil red *O*. Immuno-electrophoresis (Fig. 3) suggested that the mucopolysaccharides were not antigenic in the rabbit since precipitation did not occur in the corresponding area of migration. However, this apparent lack of antigenicity may be due to alteration of the material during acid precipitation or to a difference in complexity of the substance as it existed in the serum which was used to immunize the animal. Indeed, the fast-migrating mucopolysaccharide was not detectable in untreated serum (1, *A*) or pleural fluid. Within the necessary limitation placed on the extent of separation, all fractions of the latter two specimens appeared to contain mucoprotein (2, *D*). Following acid precipitation, the α_1-globulin was the only main serum fraction staining with the dye. This suggested that the mucopolysaccharide represented prosthetic groupings split from the mucoproteins of other serum fractions during acid treatment. Although the present evidence indicated this possibility, it may be emphasized that concentration of the samples was not attempted and, therefore, the existence of 'free' mucopolysaccharide cannot be excluded since the concentration may be below the limits of detectability. Regardless of the origin, it would appear important to gain further information concerning the biological properties of the isolated mucopolysaccharide.

The use of agar in electrophoretic studies such as these offers certain advantages over paper methods. Separation of the various components is accomplished more rapidly without loss of detail, and the apparatus is of very simple design. The elimination of elution procedures prior to immunological investigation also favours the present method.

These investigations were supported by a grant (*E*-2653) from the National Institutes of Health, Bethesda.

A New Technique for studying the Quantitative Aspects of Cytochemical Reactions and its Application to the Feulgen Reaction

Quantitative microspectrophotometry of cytochemically stained substances in cellular structures should be based on a knowledge of the stoichiometry of the reactions involved and the conditions influencing it. Thus far independent chemical analysis of individual cellular structures to study the quantitative relation between colour and amount of stained substance in general is not possible. This relation can be studied on a macro-scale by incorporating the substance in a kind of artificial section or model system which makes it possible to carry out the staining procedure under cytochemical conditions. For this purpose thin cellulose films were chosen. The extinction of the film after the staining procedure is proportional to the mass of the stained substance per unit area in the film. This mass is proportional to the amount of cellulose in the same area, provided the substance is uniformly distributed.

Since the cellulose films can be made of reasonable strength this amount of cellulose per unit area can be found by punching out pieces of known diameter in the measured region and weighing the dried punches. If no loss of substance occurs during preparation and staining of the model system the mass of stained substance per punch weight can be derived from the calculated composition of the film as a whole.

If an analysis method for the substance is known or can be developed this method can be used to analyse individual punches directly at the end of the staining procedure. Such analysis makes the method independent of initial irregular distribution or irregular loss of the substance in different areas of the film. Another advantage of the use of cellulose films is their favourable optical properties, which permit the study of spectra of the incorporated substance down to 230–240 mμ.

To demonstrate the value of this system, deoxyribonucleic acids were incorporated in a cellulose film.

The model system was prepared from a solution of deoxyribonucleic acid in viscose spread in a thin layer on a glass plate. This layer was dried somewhat at 60° C. and converted in a cellulose film in which deoxyribonucleic acid was quantitatively incorporated through the action of a mixture of 3 vol. methanol and 1 vol. formic acid. The films were fixed overnight in a mixture of 30 per cent formaldehyde and methanol (1/9 v/v). After having been kept in methanol for some days, the films were subjected to the Feulgen reaction (hydrolysis for 12 min. at 60° C. in 1 *N* hydrochloric acid). The stained films as well as their appropriate controls were cut into small strips. These strips were transferred to a spectrophotometer cell filled with *o*-xylene and were held mechanically in a stretched position. After the measurement of the extinction a round piece of each strip was punched out in the region that had been traversed by the light beam. The dried punches were weighed and analysed for inorganic phosphorus after digestion in a perchloric acid–hydrogen peroxide mixture. The standard deviation of the mean of the values of phosphorus content per mgm. dry cellulose of the unstained punches could be kept within 1 per cent.

The result of an experiment in which films of various concentrations of deoxyribonucleic acid were used is given in Fig. 1. From each film strips were cut,

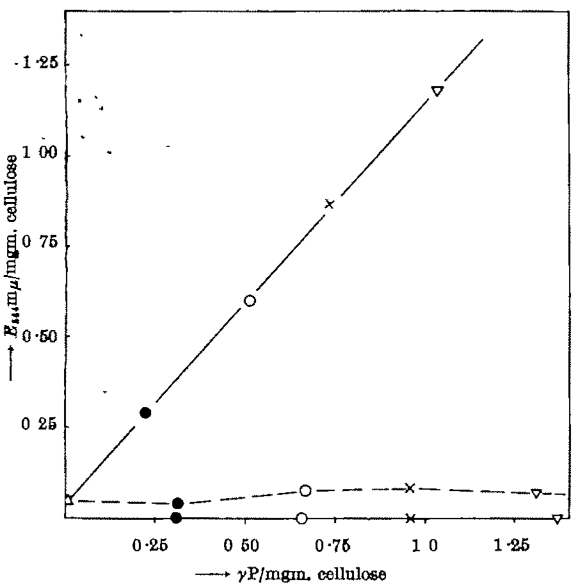

Fig. 1. Schiff-stained deoxyribonucleic acid–cellulose membranes. ———, Hydrolysis; – – – –, no hydrolysis. The phosphorus content of the unhydrolysed and unstained membranes ($E <$ 0·005) are plotted on the abscissa. The dry weight of the punches (diam. 5·49 mm.) varied between 0 55 and 0 80 mgm.; their thickness in xylene was found to be in the range 60–80μ

which were stained omitting the hydrolysis procedure. The results show that a linear relation exists between the deoxyribonucleic acid content after staining and the value of the extinctions measured. This linearity is not influenced by the formaldehyde treatment and in general is independent of the way in which the films are prepared from the viscose layer. Since the points in the graphs are based on mean values from five to six punches, an impression of the accuracy of the method can be gained from the standard deviations for the quotient $E/\gamma P$ of the individual punches, given in Table 1. These results give further proof of the validity of the Feulgen reaction as a quantitative method for deoxyribonucleic acid.

Table 1

Groups of punches*	γP/mgm dry cellulose (calculated)	Mean $E_{546}/\gamma P$
●	0·321	1 12 ± 0 085† (6)‡
○	0 70	1 10 ± 0 088 (6)
×	1 00	1 13 ± 0 083 (5)
▽	1·40	1 10 ± 0 02 (6)

* See Fig. 1. † Standard deviations. ‡ Number of punches.

Cytophotometry of Feulgen-stained cell nuclei in general is carried out on an empirical basis, working with arbitrary units of deoxyribonucleic acid content within a certain experiment[1]. Based on the hypothesis of the constancy of the amount of deoxyribonucleic acid in cell nuclei within one species, macro-analysis of suspensions of cell nuclei in this particular case could be used to some extent to investigate the stoichiometric relations involved, as was done by Ris and Mirsky[2]. The use of an artificial section may facilitate the study of the factors influencing the stoichiometry of the Feulgen reaction. Such studies may contribute to the solution of the problem if the deviations from the constancy hypothesis, still found by microspectrophotometry of Feulgen-stained nuclei, are based on real variations in deoxyribonucleic acid content.

The system seems suitable for testing the behaviour of other aldehyde reagents instead of the Schiff reagent in the Feulgen reaction. In this respect we investigated the behaviour of the blue thionine–SO_2 aldehyde reagent reported previously[3]. These studies show a similar linear relation between extinction (at 590 mμ) and deoxyribonucleic acid amount as was found for the Schiff reagent.

Investigations with the aid of the model system may facilitate the finding of staining conditions that reflect to some extent the positions of the aldehyde groups in the apurinic acids from several types of deoxyribonucleic acid.

Since its value has now been proved for the Feulgen reaction it appears reasonable to extend the method to compounds other than deoxyribonucleic acid for which a study of the stoichiometric relation cannot be based on a constancy hypothesis.

In its present form the method is limited to the investigation of quantitative cytochemical behaviour of alkali-stable substances. Removal of the excess alkali from the viscose just before mixing and film formation seems possible. In addition other cellulose derivatives with film-forming potentialities are known to exist so that the present limitations appear to be surmountable.

Part of this work has been published as a thesis for a Ph.D. degree by one of us[4].

Full details will be published elsewhere. We wish to thank Miss J. Allaart for technical assistance.

Biological Significance of Peptide containing Hydroxyproline during the Development of Carrageenin Granuloma

ALTHOUGH it is generally accepted that free hydroxyproline cannot be utilized for the synthesis of collagen[1–3], we have demonstrated in previous papers a close interrelation between the level of free hydroxyproline in tissues of rats[4], or in the body of chicken embryos[5], and the rate of collagen synthesis (after cortisone administration). In a recent paper Green and Lowther[6] presented proofs that the formation of protein-bound hydroxyproline proceeds by way of 'activated' proline which is hydroxylated during the incubation in granuloma slices to form 'activated' hydroxyproline. The possibility of such a hydroxylation of proline *in vitro* has been demonstrated recently[7]. Some hypotheses dealing with collagen synthesis presume in connective tissue the presence of peptide with hydroxyproline, the biochemical existence of which has not yet been proved. In an ultrafiltrate of extracts from bovine embryonic tissues homogenates (subcutis, growth-zone of bones) we found repeatedly several peptides containing hydroxyproline. Their chromatographic and other biochemical characteristics will be published elsewhere (Kobrle, V., and Chvapil, M.).

In this study are presented further findings concerning the biological significance of peptide or peptides containing hydroxyproline.

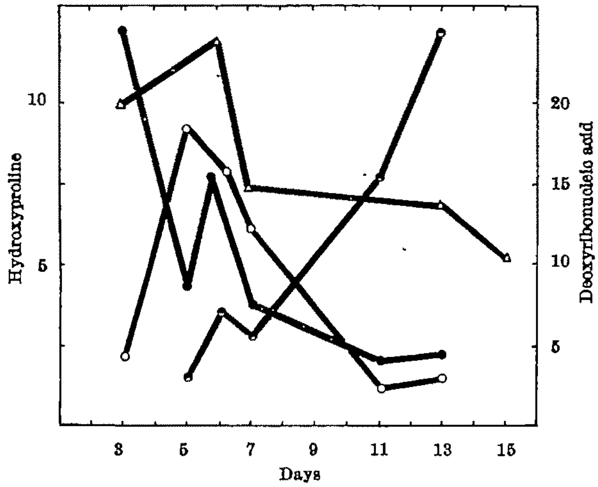

Fig. 1. Changes in free and peptide hydroxyproline, total tissue hydroxyproline and deoxyribonucleic acid concentration during the development of carrageenin granuloma. ○, Peptide hydroxyproline; ●, free hydroxyproline; ◒, total tissue hydroxyproline; △, deoxyribonucleic acid. Results are presented in μgm./100 mgm. of dry substance

For this reason carrageenin granuloma in guinea pigs was produced by the usual technique[8] under simultaneous penicillin and streptomycin treatment. On individual days of the development of the granuloma until the fifteenth day, the tissue was collected, homogenized with the aid of air as fluid and with a Potter and Elvehjem apparatus, extracted 60 min. with $0{\cdot}14\ M$ sodium chloride. The whole homogenate was centrifuged at 15,000g; the proteins in the supernatant were separated by means of ultrafiltration in metal pressure ultrafilter using a membrane supplied by Nojax Cellulose Casinas, Visking Corp., Chicago. The absence of proteins in ultrafiltrate was always re-examined. An aliquot of the ultrafiltrate was hydrolysed ($6N$ hydrochloric acid, 140° C., 3 hr.). In hydrolysed and non-hydrolysed parts of the filtrate we determined colorimetrically the amount of hydroxyproline[9], and the total amount of imino-groups[10] polarographically. In an aliquot of the whole homogenate we determined after acid hydrolysis the total hydroxyproline[9], and in another aliquot the amount of deoxyribonucleic acid[11]. Two independent series of experiments were carried out with similar results.

Results of a second series of experiments are summarized in Table 1 and Fig. 1.

It is evident that in the first days of granuloma development there occurs an accumulation in tissue of peptide containing hydroxyproline which forms 20–65 per cent of total filtrable hydroxyproline. It is worth mentioning that the changes in peptide–hydroxyproline follow the changes in amount of deoxyribonucleic acid in tissues. In good agreement with the findings of Jackson[12], the maximum of collagen accumulation is 7–10 days.

The level of free hydroxyproline in granuloma tissue diminishes at first, and then alters simultaneously with peptide.

The presence and the amount of peptide with hydroxyproline in an ultrafiltrate does not depend on whether the tissue homogenate was heat-treated (100°, 10 min.) or not. For this reason we exclude the possibility that peptide hydroxyproline is the source of collagen degradation by some tissue enzymes.

We suppose, therefore, that the accumulation of peptides containing hydroxyproline in their molecule in carrageenin granuloma is connected with early collagen protein synthesis, or stimulated collagen production bound on the presence of fibrillogenic connective tissue cells. The interrelation of free hydroxyproline and peptide–hydroxyproline is not yet quite clear. The elucidation of these questions is the task of further studies.

Table 1

	Duration of experiment (days)					
	3	5	6	7	11	13
Free hydroxyproline*	12·4	4·4	8·04	3·84	1·94	2·27
Peptide hydroxyproline	2·2	9·3	8·05	6·18	1·16	1·58
Percentage of peptide-hydroxyproline†	15	68	50	60	37	40

Flavonoid Compounds in the Inflorescence of *Helichrysum arenarium*

In a previous paper[1] we reported the isolation and identification of three crystalline compounds from the inflorescence of *Helichrysum arenarium*. We isolated from the alcoholic extract the salipurposide, naringenin-5-glucoside (5,7,4′-trihydroxyflavanone-5-glucoside), $C_{21}H_{22}O_{10}\cdot 2H_2O$, m.p. 219–224°, yield 0·25 per cent, acetyl derivative m.p. 174–177°. Until then, this flavanone glucoside had been found only in *Salix purpurea* and *Acacia floribunda*.

We also isolated the apigenin (5,7,4′-trihydroxyflavone), m.p. 346°, yield 0·03 per cent (triacetyl derivative m.p. 179·5–181·5°, dimethyl derivative m.p. 155–156°), which occurs in dried flowers in a free state. After hydrolysis with dilute sulphuric acid of a syrupy fraction, which could not be obtained in crystalline state, we isolated the kæmpferol (3,5,7,4′-tetrahydroxyflavone) $C_{15}H_{10}O_6$, m.p. 276–278°, yield 0·1 per cent; triacetyl-derivative m.p. 177°.

Now we have obtained evidence that kæmpferol occurs in *Helichrysum arenarium* as a glucoside.

Using paper partition chromatography we have shown, besides salipurposide, the presence of still two other flavonoid compounds. (Whatman No. 3 circular-paper chromatography, ethyl acetate–formic acid–water, 10 : 2 : 3, $R_F = 0{\cdot}84$, $R_F = 0{\cdot}77$.) One compound could be isolated in pure state, $C_{21}H_{20}O_{11}$, m.p. 171–175°, R_F = 0·84, yield 0·1 per cent (calc. C, 56·25; H, 4·50; found: C, 55·89; H, 4·54) and identified with kæmpferol-3-glucoside (astragaline). This substance hydrolysed with acid gives a compound with m.p. 278–280°, R_F = 0·87 (Whatman No. 1, *n*-butanol–acetic acid–water, 4 : 1 : 5) identified with kæmpferol, and glucose identified by paper chromatography (R_F = 0·18) and its osazone.

By methylation and thereafter hydrolysis a crystalline compound, m.p. 148–149°, identical with 5,7,4′-trimethylkæmpferol was isolated. This provides evidence of location of the glucosidic linkage at position 3.

Our R_F value distinctly differs from the observed one by Hörhammer[2], R_F = 0·67, in the same solvent system.

The simultaneous occurrence in the same plant of three grades of oxidation of the flavonoid nucleus—flavanone, flavone, flavonol (naringenin, apigenin, kæmpferol)—is interesting. One may suggest the possibility of biosynthesis of apigenin from naringenin and of kæmpferol from naringenin or apigenin.

Analogous oxidations were realized by iodine, selenium dioxide and hydrogen peroxide *in vitro*.

The results of pharmacological study now under investigation will show if the flavonoid compounds which we have isolated are responsible for the cholagogue activity observed for the drug.

The crude extract, containing apigenin as major compound, showed in preliminary trials cholagogue activity, and another, containing salipurposide and kæmpferol-3-glucoside, showed a spasmolytic activity and a feeble cholagogue one (A. Szadowska, Department of Pharmacology, Med. Academy; more extensive results will be published elsewhere).

PHYSIOLOGY

Improvement of the Intravenous Glucose Tolerance Test

GLUCOSE is carried to its metabolic sites directly by plasma water and only indirectly by red blood cells. Accordingly, the intravenous glucose tolerance test would convey greater information if it were reported in terms of plasma glucose concentration. Yet whole blood is currently used in such determinations. Whole blood contains glucose in both red blood cells and plasma, and since the transport between them is moderately slow the concentrations are generally different when blood glucose-levels are rapidly changing. For example, if plasma water glucose concentration is suddenly raised from 100 to 200 mgm. per cent, data of Bowyer and Widdas[1] indicate that it would take 17 min. for the glucose concentration in the red blood cell water to reach 190 mgm. per cent.

Slow transport brings into question interpretations based upon a simple exponential model for the intravenous glucose tolerance test[2]. For if the glucose concentration curve for the whole blood is a simple exponential function, and if slow transport occurs, then the plasma glucose curve cannot be a simple exponential function. The complex shape of the plasma glucose concentration curve can best be understood in terms of a model shortly to appear[3].

This complex model depends upon inferences about plasma glucose concentrations, because experimental data are not available. The utility of the model would be materially enhanced by direct experimental determinations of plasma glucose concentrations during the intravenous glucose tolerance test. Such determinations could readily be obtained by immediate refrigeration and prompt centrifugation of blood samples to retard transfer. Such refrigeration could be obtained by drawing the blood through polyethylene tubing immersed in ice water. The difficulties of intra-arterial cannulation can be obviated by using venous blood after warming the arm.

Abrupt and Delayed Effects of Insulin on the Distribution Space of Glucose in the Dog

IT has been proposed that insulin increases the permeability of cell membranes of animals to glucose[1]. If this is so, an increase induced by insulin in the volume through which glucose can disperse could occur as a result of the addition of intracellular spaces to those through which glucose is distributed without the added insulin. The method of successive tracer injections[2] provides a means for determining, at each injection time, the amount of glucose which intermixes rapidly with the plasma glucose. From this value the corresponding apparent volume or space of distribution can be calculated, assuming that the concentration of plasma glucose is uniform throughout the volume. In this communication these procedures were used to determine the immediate and later effects of injection of insulin and of infusion of insulin on the glucose distribution space of the dog.

Five experiments were performed on four normal dogs anæsthetized with nembutal. Glucose, uniformly labelled with carbon-14, was injected intravenously through an indwelling polyethylene cannula inserted 3–4 in. into the tibial vein. Samples were withdrawn from the inferior vena cava, which was catheterized via the femoral or saphenous vein. Insulin was given

* In this experiment volume of glucose was measured at injection time. It was 12·5 per cent of body-weight.

† This determination is based on a specific activity versus time curve of a very poor fit. Therefore it may represent a gross over-estimation of volume of glucose. It is included in order to present unselected results.

either as a single intravenous injection, or as a constant intravenous infusion from a calibrated burette. Glucose was determined by the Somogyi–Nelson method[3]. Specific activity of plasma glucose was measured by preparing glucosazones, the radioactivity of which was measured in a windowless flow-counter. In experiments 1 and 3 (Table 1) Insulin-Toronto was used, whereas in the others crystalline Insulin-Lilly was injected.

Results are shown in Table 1. It can be seen that the injection of insulin resulted in an increase in the apparent glucose volume in all experiments. The effect is a delayed one and is not strictly related to the changes of level of blood glucose. It can be seen in experiments 3 and 6 that, although the level of blood glucose had started to drop, the increase in apparent glucose volume was delayed. In experiment 7A, the level of blood glucose had returned to normal, while the apparent glucose volume was still somewhat above the pre-insulin level. In experiment 1 the glucose volume was determined at the time of insulin injection and was found to be slightly less than the pre-insulin volumes. This is in accord with our earlier findings[2].

The present experiments do not indicate whether the effect of insulin on the apparent glucose volume is a specific one, or whether it results from the hypoglycæmia evoked by insulin. Experiments to elucidate this point are in progress.

In support of the present findings it has been shown that insulin increases the volumes of distribution of galactose and of some pentoses in the eviscerated dog[4], in isolated tissues[5], and in perfused organs[6]. Under certain conditions an accumulation of free glucose in the isolated rat diaphragm was also noted when insulin was added to the incubation medium[7].

The effect of insulin on the apparent glucose space was studied by Drury and Wick[8], who compared two groups of eviscerated-nephrectomized rabbits. One group served as controls, while the other received 10 units kgm./hr. of insulin. No difference in the apparent glucose spaces was found. Each of our experiments with successive tracer-glucose injections was performed on a single dog, so that inter-animal variation was avoided. All our results show an increase in the apparent glucose space during insulin hypoglycæmia, but not immediately after the start of the injection of insulin. The enlarged space appears to exceed that of the extracellular body-water.

This finding modifies the conclusions from earlier experiments, in which attempts were made to determine the effects of insulin on the rates of appearance and disappearance of glucose from the plasma and associated tissue fluids (central compartment). All these methods except one[2] involved the assumption that the glucose space remained constant. The observed increase in the apparent glucose space following injection of insulin leads to an under-estimation of the rate of appearance or an over-estimation of the rate of disappearance of glucose, the extent of which may vary with experimental conditions.

To sum up: the injection or infusion of insulin caused no immediate increase in the apparent glucose space in the normal dog. However, in each of the five experiments, a substantial increase was found 1 hr. or less after the injection, or after the start of the infusion of insulin.

This work was supported by grants from the National Research Council of Canada and the Banting Research Foundation. We thank Dr. C. H. Best for his encouragement and support in this work. The generous gift of glucagon-free crystalline insulin (Lot 499667) by the Eli Lilly Company is gratefully acknowledged. Our thanks are due to Mr. G. Layng for technical assistance.

Effect of Vitamin A on the Cystine Content in Skin of Rats

THIS investigation was undertaken to gain more precise knowledge of the effect of vitamin A on the epithelium. Diets ranging from a small dose to a liberal supply of vitamin A were fed to rats, and the cystine content of their skin was determined.

The analytical results show that the skin of rats on a diet supplemented with only small doses of vitamin A contained less cystine than that of rats which had been fed with a liberal supply of vitamin A.

The current theory[1] of keratin formation includes oxidation of cysteine sulphydryl groups of adjacent polypeptide chains to produce cystine disulphide linkage, the covalent bonds of the latter grouping serving to hold the keratin molecule together and give it rigidity. Since vitamin A deficiency leads to excessive keratinization of epithelium, the possibility that the vitamin A may be concerned in the metabolism of sulphydryl and disulphide linkages deserves scrutiny. This observation led to our investigating the change in cystine content in the skin of rats which had been fed diets supplemented with small doses and large doses of vitamin A, with or without sulphur amino-acids.

The test animals used were rats of the Wistar strain of both sexes, those used for the first experiment weighing 30–35 gm., those for the second, 65–70 gm. They were housed in individual compartments with screen bottoms and fed a vitamin A-deficient ration consisting of powdered rice 92, defatted soybean meal 6, sodium chloride 1 and calcium carbonate 1. In addition, each rat was supplied with 20γ thiamine and 50γ riboflavin daily. The food was made into a paste by adding hot water, and cooked. After a three-week depletion period the animals were transferred to the experimental diets. At the end of four weeks the animals were beheaded. After shaving about 5 cm.^{2} of the back of the neck in the area of the shoulder blades, samples of skin were taken from each animal, dried and defatted with ethyl alcohol–ethyl ether. Weighed samples of it were hydrolysed in 3 *N* hydrochloric acid at 120° C. for 4 hr. The cystine content in the hydrolysate was analysed by the phosphotungstic acid method[2].

The cystine content of skin should be affected by the amount of sulphur amino-acid in the diet. In the first experiment, we investigated the effect of the small dose and the effect of the liberal supply of vitamin A in the diet, with or without a supplement of methionine, on the cystine content of the skin. The four groups of rats were given different diets as described in Table 1.

Table 1. AMOUNT OF SUPPLEMENTS IN EXPERIMENT 1

Group No.	1	2	3	4
Vitamin A per rat daily (γ)	1	100	1	100
DL-Methionine (gm.) per 100 gm. of diet	none	none	0·2	0 2

Rats in Group 1 were dosed with only 1γ of vitamin A per rat daily, which is a low dose. Animals in Group 2 were given 100γ of vitamin A—an ample dose. Groups 3 and 4 were dosed with 1γ and 100γ of vitamin A respectively supplemented simultaneously with methionine. During the four-week feeding period, the amount of diet was restricted to 7 gm. per rat daily the first week and thereafter increased each week by 1 gm. a week.

In the second experiment cystine was used instead of methionine and was given in conjunction only with the lower dosage of vitamin A (Table 2).

Table 2. AMOUNT OF SUPPLEMENTS IN EXPERIMENT 2

Group No.	1	2	3
Vitamin A per rat daily (γ)	1	100	1
L-Cystine (gm.) per 100 gm. of diet	none	none	0·2

Table 3. EFFECT OF VITAMIN A AND METHIONINE ON THE CYSTINE CONTENT OF SKIN

Values shown with mean and standard deviation of six rats in each group

Group No.	1	2	3	4
Supplement to diet	1γ vit. A	100γ vit. A	1γ vit. A + methionine	100γ vit. A + methionine
Body-weight (gm.):				
Initial	36 3 ±2 13	36 5 ±2 50	36·5 ±2·50	36·5 ±3 10
Gain per day	1·86±0·098	1·96±0·120	1·94±0·070	1 98±0·102
Skin: cystine (per cent)	1·36±0 083	1·60±0·102	1·50±0·132	1 68±0 220

Results of the first experiment show that the cystine content of skin of rats dosed with only 1γ of vitamin A is lower than that of rats given a liberal allowance of vitamin A. In the presence of methionine, the cystine content increased both with small and large doses of vitamin A; however, rats with the ample supply of vitamin A showed a higher content of cystine.

The results of the second experiment were essentially similar to those of the first experiment (Table 4).

Table 4. EFFECT OF VITAMIN A AND CYSTINE ON THE CYSTINE CONTENT OF SKIN

Values shown with mean and standard deviation of six rats in each group

Group No.	1	2	3
Supplement to diet	1γ vit. A.	100γ vit. A	1γ vit. A + cystine
Body-weight (gm.):			
Initial	74·8 ±7·54	74·6 ±6·36	74·6 ±8 31
Gain per day	1·89±0·172	2 04±0·189	2·00±0·269
Skin: cystine (per cent)	1·18±0·135	1·53±0·082	1·41±0 205

The cystine content was lower in group 1 and higher in groups 2 and 3, which received an ample supply of vitamin A, and cystine with small doses of vitamin A respectively. The results were in good agreement with the first experiment.

Abdulnabi and Bieri have studied the distribution pattern of amino-acids in the testes and livers and the blood serum of both vitamin A-deficient and normal rats. Paper chromatography did not reveal any difference between the two groups, and the quantitative picture, as obtained by microbiological assay, in general supported the qualitative results. There were, however, three quantitative differences. In the testes of the deficient rats, there was more tyrosine and phenylalanine, whereas in the normal livers there was more threonine than in the livers from the deficient rats.

Our results show that in the skin of the vitamin A-deficient rats there was less cystine than in that of normal rats, suggesting that vitamin A may be involved in the metabolism of cystine and may have an effect on the resistance of epithelium.

BIOLOGY

A Method of staining Sectioned Tissues with Lead for Electron Microscopy

SOLUTIONS of lead are now widely used by some electron microscopists for the production of a general increase in the electron density of cellular constituents in sections of biological material fixed in osmium tetroxide and afterwards embedded in methacrylate or 'Araldite'. Grids bearing the sectioned specimens may be floated face downwards for a few minutes on the surface of weakly ionized lead solutions, for example, lead acetate or 'alkaline' lead hydroxide[1]. During this exposure lead ions become attached to the osmium already deposited on the material during fixation, with a consequent improvement of specimen contrast in the electron beam.

The effective application of these methods of lead impregnation has been somewhat curtailed by the fact that on exposure to air all solutions of lead salts become clouded by the formation of lead carbonate, the insoluble crystals of which are frequently encountered on the surface of sections stained by this method. In order to reduce this contamination attempts can be made to stain the specimens in a nitrogen or carbon dioxide-free atmosphere[2]; but these measures do not entirely eliminate the nuisance.

Successful lead staining without serious disadvantages can be effected as follows: Add 100 c.c. of distilled water to 1 gm. lead hydroxide and bring to the boil. Cool slightly and filter. To the filtrate, which is faintly clouded, add a solution of 2 *N* potassium hydroxide drop by drop until on agitation a completely clear solution remains. This is the staining fluid and probably contains some lead in the form of a plumbite, thus:

$$2KOH + Pb(OH)_2 = K_2PbO_2 + 2H_2O$$

Float the grids face down on a few drops of this solution in a covered watch-glass for 5 min. Then with a pipette replace the staining solution with distilled water and proceed at leisure to remove the grids individually with forceps. Agitate each grid for some 3–4 sec. (only) in a 1 per cent solution of potassium hydroxide and then immediately dip into a large volume of distilled water. Finally blot the grids on to filter paper and allow them to dry. Some experience is required to gauge just the right amount of time for the cleaning of the specimens in the 1 per cent potassium hydroxide (after staining). If this period is inadequate the grids show some contamination by crystals which are, however, readily removed by further immersion in potassium hydroxide. On the other hand, it has been observed that if lavage in the alkali is too prolonged then lead impregnation of the specimen appears to be reduced.

5-Hydroxytryptamine in Coelenterates

In an earlier report[1], it was concluded from evidence obtained by pharmacological tests and paper chromatography that 5-hydroxytryptamine was a constituent of the sea-anemones, *Metridium senile* and *Calliactis parasitica*. More 5-hydroxytryptamine-like material was obtainable from *Metridium* tentacles, with their nematocysts, than from body wall which is relatively free of nematocysts. This led to the suggestion that 5-hydroxytryptamine might be a pain-producing factor in these stinging organelles. An independent study[2] of material released on discharge of isolated *Metridium* nematocysts yielded two hydroxyindoles tentatively identified by chromatography as 5-hydroxytryptophan and bufotenine. The identification of 5-hydroxytryptamine in *Calliactis* has now been made quite certain[3,4]. However, the very large amount found in the coelenteric organ of this species and the relatively small amount in tentacles, coupled with the finding of little 5-hydroxytryptamine in *Metridium* and *Anemonia sulcata*, led Mathias, Ross and Schachter[3,4] to conclude that it is unlikely that 5-hydroxytryptamine is associated with nematocysts. Further evidence is now available that this conclusion may not be fully warranted.

With a highly sensitive fluorescence method for the estimation of 5-hydroxytryptamine now available[5], as well as a suitable method for extracting it from tissues[6], it has been possible to confirm and extend our earlier observations on the distribution of a substance like 5-hydroxytryptamine in different parts of *Metridium*. The content of 5-hydroxytryptamine of certain other coelenterates has been estimated by this method.

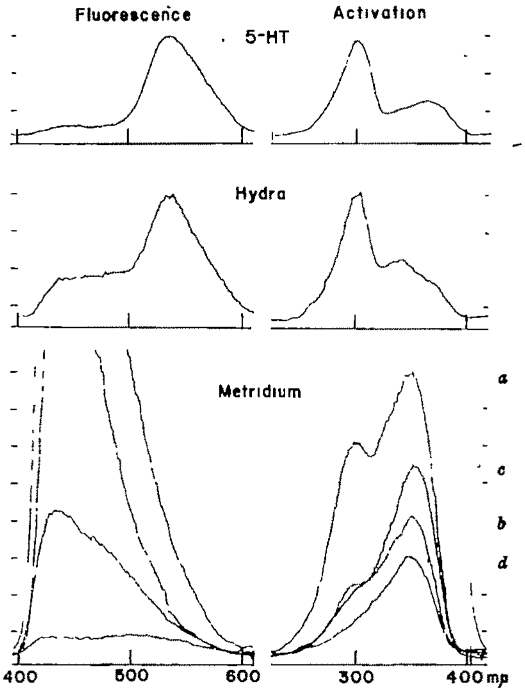

Fig. 1. Fluorescence and activation spectra: 5-HT, 0·1 μgm. 5-hydroxytryptamine/ml. 3 *N* hydrochloric acid; *Hydra*, extract of 0·38 gm. *Hydra oligactis* in 4·2 ml. 3 *N* hydrochloric acid. *Metridium*, (*a*) 0·24 gm. acontia; (*b*) 4·1 gm. body wall; (*c*) 2·8 gm. tentacles (each tissue extracted into 4·5 ml. 3 *N* hydrochloric acid); (*d*) reagent blank

In the presence of 3 *N* hydrochloric acid, there is a fluorescence maximum for 5-hydroxytryptamine at about 540 mμ when activated at 300 mμ (Fig. 1). These are the observed values obtained with the particular spectrofluorometer at our disposal. Bufotenine has a similar fluorescence to that of 5-hydroxytryptamine, but of the coelenterate extracts that we have examined chromatographically only those from *Physalia* tentacles gave an indole spot with an R_F value corresponding to that of bufotenine.

An extract of whole brown *Hydra* contained little interfering substance and gave obvious fluorescence and activation peaks (Fig. 1). Estimations of 5-hydroxytryptamine in one lot of *Hydra* and two lots of *Sagartia*, a small sea anemone, are given in Table 1. Extracts of *Metridium* tissues were found to contain a substance that fluoresces strongly near 430 mμ, thereby obscuring the 540-mμ peak of 5-hydroxytryptamine. Activation peaks were easily

Table 1. 5-Hydroxytryptamine in Coelenterates

Species and part	5-Hydroxytryptamine equivalents μgm./gm. fresh tissue
Hydra oligactis	
Approximately 1,000 whole animals	1·5
Sagartia luciae	
15 whole animals per determination	0·74 1·8
Metridium senile	
Whole animals*	0·04; 0·05; 0·05
Body wall	0·02; 0·05; 0·09
Oral disk and tentacles	0·08; 0·12; 0·17
Tentacles	0·24; 0·47
Acontia	0·60; 0·97; 1·30

* Three extractions and estimations made on the same day on animals maintained in laboratory for several weeks.

distinguished, however, and quantitative estimates were made from them (Fig. 1).

Different parts of *Metridium* were chosen to contain: (1) few nematocysts (body wall); (2) an abundance of nematocysts (tentacles or acontia); (3) a number intermediate between these (oral disk with tentacles). Two or three extractions were made of each of these parts. Some were made on freshly collected *Metridium* and others on animals that had been maintained in the laboratory for some months without feeding. Estimates of the content of 5-hydroxytryptamine of these extracts are given in Table 1. For a given part a range of values was found, attributable, in some measure, to the previous history of the individuals that were utilized. However, it is clear that *Metridium* body wall yielded least 5-hydroxytryptamine while the acontia, rich in nematocysts, yielded nearly 20 times as much as body wall. Other parts were intermediate. As a result of these findings, I am inclined to state, as earlier[1]: "This suggests, but does not prove, that the 5-HT (of *Metridium*) is contained in nematocysts . . .".

Mathias *et al.*[4] say that of several coelenterates they examined, significant amounts of 5-hydroxytryptamine were found only in *Calliactis parasitica*, and by far the highest concentration in "tissues of the coelenteric cavity". Thus far, 5-hydroxytryptamine in invertebrates has been found in venom apparatus and venoms[7], also nervous systems and excretory organs[8]. It would be of much interest to determine in which coelenteric tissue of *Calliactis* the 5-hydroxytryptamine is located. In the meantime it seems that the distribution of 5-hydroxytryptamine in *Metridium* is related to the distribution of nematocysts; but no claim is made that this is a specific (restricted) relationship.

Selective Elimination of Single Sense Cells with Methylene Blue

FOR many problems of epigenetics and physiology it is desirable to destroy selectively individual cells within a tissue complex in order to test their functions. Although, in favourable cases, such cell structures as the nucleus have been eliminated, whole-cell destruction often implies damage to the surrounding tissue. Another difficulty of such experiments is the fact that recognition of single living cells within the tissue may be impossible. The use of toxic substances of sufficient specificity to affect the cell type to be eliminated, but without effect on other cells or on the organism as a whole, would solve this problem. A possible avenue of approach seems to be through techniques involving vital or supravital dyestuffs. The actual method must, of course, depend upon the type of cell to be eliminated. The experiments to be described illustrate this method of selective cell elimination by means of a chemical. The cells to be eliminated were single sense cells.

Young pupæ of the wax moth, *Galleria mellonella* L., were used in this work. Ether narcosis of half-hour duration served to immobilize the animals for several hours. Crystalline methylene blue is introduced with the point of a fine iridectomy knife. It dissolves at once in the hæmolymph, which takes a dark blue stain. Through carefully applied pressure, the blue hæmolymph is now distributed in the region to be studied. After ½–1 hr., the sense cells and the nerves are stained and they are now perceptible *in vivo* through the thin cuticle. Generally the nerves are less intensely stained than the sense cells. Body movements of the animals after recovering from narcosis distributed the dyestuff more evenly. After some time all dye will be reduced to its leuco form. Practically all animals survive the operation without showing any defect.

Study of slides from fixed material shows the stain exclusively located in the sense cells, disregarding those cells at the wound which were damaged by the operation. Some of the sense cells are stained light blue, others are dark blue. This difference in staining intensity is shown even by the sense cells of the same sensillum. According to statements in the literature[1], it is to be expected that at least the dark blue cells are destroyed. This is confirmed by histological study. Fig. 1 shows groups of cells

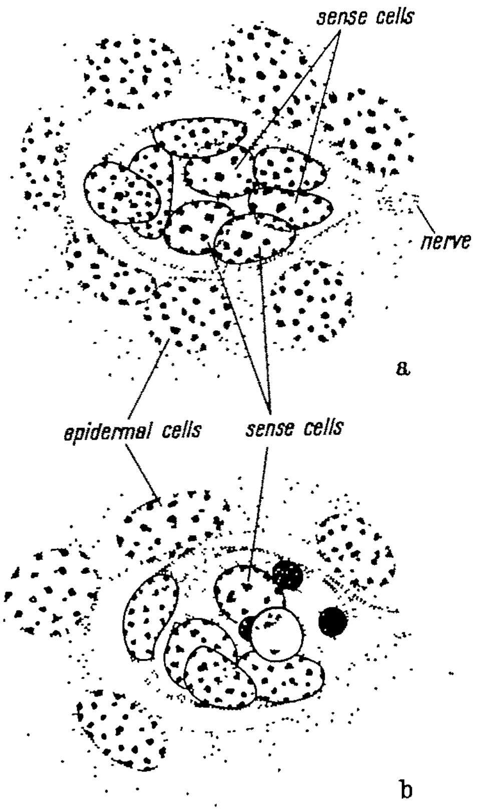

Fig. 1. Cell groups which belong to sensory bristles on the wing of *Galleria*. *a*, A normal cell group; *b*, a cell group in which three sense cells are destroyed by methylene blue. Nuclei which do not belong to the bristle have dotted lines. Pupæ, 25 hr., Bouin-Allan fixed, stained with hæmatoxylin

belonging to sensory bristles on the wing before outgrowth of the bristles themselves. The normal cell complement of such bristles (Fig. 1*a*) consists of eight cells, four of which are sense cells. The others are the trichogen and the tormogen cell and two cells of still unknown function, called *Hilfszellen*[1]. In the group of cells shown in Fig. 1*b*, three sense cells are damaged by methylene blue; two nuclei are pycnotic, one is swollen up like a blister, with clotted chromatin. This pupa was fixed for about 20 hr. after treatment with methylene blue. In animals which were fixed later the sense cells are completely decayed. The fourth sense cell and the four other cells in Fig. 1*b* are not damaged. Such cell groups as in Fig. 1*b* perform their normal function, that is, they give rise to entirely normal bristles, only with a reduced number of sense cells. This indicates that they are physiologically normal.

According to our experience certain prerequisites are necessary whenever a method of selective cell elimination through the use of specific substances is to be applied. (1) It must be possible to localize the toxic substance and to maintain a high concentration for a period of time in the region under study (narcosis; sack-like organs, see below). (2) The substance should be easily distributed (spongy tissue, much hæmolymph). (3) The substance should be implanted in as pure a state as possible, for example, not dissolved in another fluid. Conditions 1 and 2 were fulfilled, in the young pupa, by the extremities, the antennæ and the wings.

By use of the method described it was possible to show that the sense cells exert an influence on the development of the sensilla in the integument of *Galleria*. If this influence is lacking, polyploidization of the trichogen and the tormogen cells does not occur. These results will be reported in detail elsewhere[3].

A Spring Oat Variety resistant to the Stem Eelworm

RESISTANCE among oat varieties to the stem eelworm, *Ditylenchus dipsaci* (Kühn) Filipjev, was first shown by Goodey[1], who recorded a high degree of resistance in the varieties Grey Winter and Aberystwyth *S*81. Since this record, resistance has been recorded among commercially grown varieties, in Milford (*S*225)[2], in *S*172, Early Grey Winter and Unique[3]. The following is a record of resistance in a new spring oat variety.

An oat variety trial in Denbighshire, conducted jointly by the National Agricultural Advisory Service and the National Institute of Agricultural Botany, had been sown inadvertently in the early spring of 1959 in a field which was later found to be infested with the oat race of stem eelworm. In the trial the varieties were sown in single drill widths 140 yards long in a randomized block lay-out with four-fold replication. Damage by stem eelworm occurred in five of the varieties—Sun II, Civena, Blanche de Wattines, Condor and *V*2661. The remaining variety, number 4757/18/2/19, a form bred by the Welsh Plant Breeding Station, Aberystwyth, showed, apart from a few isolated plants, a high degree of resistance.

The Welsh Plant Breeding Station cereal breeding department gives the pedigree of the resistant variety as a selection from a cross between 01750/11, a mildew-resistant selection developed at the station, and Tama, a crown rust-resistant selection developed at Iowa State College. The variety is to be introduced commercially under the name of Manod (*S*235).

Foliar Abnormalities, including Repeated Branching and Root Formation, induced by Kinetin in Attached Leaves of *Marsilea*

THE leaf of the water fern *Marsilea* is normally a strictly determinate structure, and even the supply of a wide range of physiologically active substances, to sporelings growing in aseptic culture, has hitherto resulted in no fundamental changes in leaf morphology[1,2]. Some interesting leaf abnormalities have now been obtained, however, following the addition to the culture medium of the cell-division stimulating substance, kinetin[3].

In the investigations outlined here, sporelings of *Marsilea drummondii* were grown aseptically in a liquid medium, consisting of a Knop's solution supplemented by glucose (analytical reagent) at concentrations of either 2 or 4 per cent. Kinetin solutions were added aseptically at various early stages of sporeling development. Resulting changes in leaf morphology were so unusual that the experiments were repeated with several batches of cultures, but all yielded essentially similar results.

In the initial experiment, kinetin was supplied to 10-day old sporelings, at concentrations of 10, 1·0 and 0·1 mgm./litre. The two higher concentrations were toxic, while at 0·1 mgm./litre sporeling development continued, but was markedly abnormal, the new growth consisting of an irregular mass of repeatedly branched structures, some of which were undoubtedly modified leaves. In later experiments, kinetin was added to give concentrations of 0·05, 0·01 and 0·002 mgm./litre. At 0·05 mgm./litre the results were virtually identical with those obtained at 0·1 mgm./litre, but at the two lower concentrations of kinetin less-extreme abnormalities were observed.

In the culture medium containing 0·002 mgm./litre kinetin. development of many of the sporelings was apparently completely normal; but in a proportion of the sporelings leaf development was somewhat affected. Some sporelings produced acicular, non-laminate leaves for a period, before reverting again to normal development, while other sporelings bore leaves with shorter petioles and longer leaf lobes than the corresponding structures of normal leaves.

The most interesting leaf abnormalities were obtained with 0·01 mgm./litre of kinetin. Most sporelings at first produced relatively normal leaves, though with short petioles. The first marked deviation from normal development was the production of several roots from the adaxial surface of some of these leaves, near the junction of lamina and petiole (Fig. 1*e*). The outgrowth of roots from *Marsilea* leaves has not been observed previously, even after the addition of so powerful a root-inducer as 2,4-D [1]. Root formation was usually followed by the appearance of a meristematic outgrowth, which in turn gave rise to a series of abnormal leaves (Fig. 1*d*). After longer exposure to the kinetin solutions the sporelings developed even more striking leaves, showing repeated branching of the leaf segments (Figs. 1*a*, *b*, *c*).

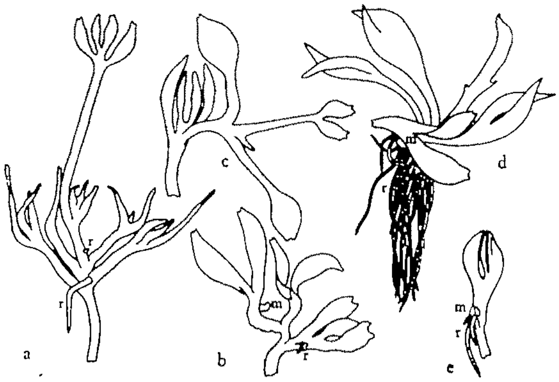

Fig. 1. *Marsilea drummondii* A.Br. Abnormal leaves from sporelings grown in a medium containing 0·01 mgm./litre of kinetin. *m*, Meristem; *r*, roots or root. (All × *c*. 2)

The leaf abnormalities briefly described above would appear to be of both phylogenetic and developmental interest. On the basis of comparative morphological studies, it is apparently generally accepted (for example, Bower[4]) that the strictly quadrifoliate adult leaf of *Marsilea* is derived from an ancestral type with more elaborate structure. The present work indicates that the potentialities of more extended development are still inherent in the *Marsilea* leaf.

Apart from its toxic action at high concentrations, the effects of kinetin appear to be restricted to meristematic tissues. In the present work, kinetin at physiological concentrations had no evident effect on fully developed leaves of *Marsilea* sporelings or on excised leaves of the same cultures. Our results suggest that the limited growth of the leaf meristems of normal plants of *Marsilea* may be due to correlations with other parts of the plant involving a restriction in the supply of cell-division promoting substances similar to kinetin. In any event, the external supply of kinetin disturbs the normal correlations and permits a more prolonged activity of the leaf meristems.

It is hoped to publish further details of this work, including anatomical observations, in a later contribution.

A Comparison of Adhering and Abscising Fruits of Peach treated with N-1-Naphthyl Phthalamic Acid

The search for a thinning spray to be used on peaches has shown that N-1-naphthyl phthalamic acid promotes abscission of peach fruits[1]. This preliminary report compares the size, content of natural auxin, and embryological development of adhering and abscising fruits of Halehaven peach trees sprayed with N-1-naphthyl phthalamic acid at petal fall.

On May 13, 1958, Halehaven peach trees at early petal-fall stage were sprayed with 175 p.p.m. of N-1-naphthyl phthalamic acid. By May 29 heavy fruit drop had started on the sprayed trees. The dropping fruits were comparable in size to those which fell from unsprayed trees a month later. This indicates that N-1-naphthyl phthalamic acid hastens drop.

150 tightly adhering fruits and 150 very loosely adhering fruits (here called abscising) were picked on May 29 from one tree sprayed with N-1-naphthyl phthalamic acid. The loosely adhering fruits probably would have fallen within 24 or 48 hr. had they been left to drop naturally. No differences in colour of the adhering and abscising fruits were observed.

Volume measurements were made on the fruits by water displacement. The ovules were then removed and physical measurements made on twenty of them. Differences in fruit volume, ovule length and weights between adhering and abscising material were not great, but in every category the adhering fruits were larger (Table 1).

Table 1. Comparison between Adhering and Abscising Fruits of Halehaven Peach Trees sprayed with N-1-Naphthyl Phthalamic Acid

	Adhering	Abscising
Volume per fruit (ml.)*	0·22	0·20
Ovule length (mm.)	3·92	3·50
Fresh weight per ovule (mgm.)	6·92	5·85
Dry weight per ovule (mgm.)	0·93	0·91
Indoleacetic acid equivalent (µgm./ovule)	0·00221	0·00031
Indoleacetic acid equivalent (µgm./gm. dry weight)	2·38	0·34
Mean number of cells per embryo	11·1	6·3
Mean number of endosperm nuclei per ovule	155	99

* Volume per fruit at bloom was < 0·22 ml.

Ovules were frozen on dry ice, lyophilized, and bioassayed for auxins using silica-gel column chromatography[2] and the *Avena* first-internode test[3]. Preliminary work with extracts of ovules collected two weeks after bloom from unsprayed Halehaven trees indicated that two growth-promoting substances could be separated. One of very low concentration was eluted in a position similar to ethyl indoleacetate, and another of somewhat higher concentration came out in the indoleacetic acid position (unpublished results). A single determination of extracts of ovules from sprayed trees and subsequent bioassay of the eluted fractions corresponding to the ethyl indoleacetate and indoleacetic acid positions were made. Ovules from both adhering and abscising fruits contained only traces of the growth-promoting substance eluted in the ethyl indoleacetate position, but there was about seven times as much of the substance similar to indoleacetic acid in the ovules from adhering fruits as from those from abscising fruits (Table 1).

Ovules were fixed in a formalin–acetic acid–ethyl alcohol (85 : 5 : 5 per cent) mixture, embedded in paraffin, sectioned at 15 or 20µ, and stained in Heidenhain's hæmatoxylin. In the nine adhering and the thirteen abscising ovules studied, embryos of about 1–23 cells and free nuclear endosperm of about 5–301 nuclei were found. As shown in Table 1, the average number of cells in the embryo and the number of endosperm nuclei of abscising ovules were about 60 per cent of those in the adhering ovules, although these means were not significantly different at the 5 per cent level of probability. In most of the abscising ovules there was more shrinkage of cytoplasm, and less differential staining of many nuclei in embryo and endosperm than in the adhering ovules. In about half the abscising ovules the embryo stained darkly. These changes in staining reaction are interpreted, on the basis of other work on seed abortion, as indicating the beginning of the breakdown of the tissues.

It appears that N-1-naphthyl phthalamic acid causes ovule abortion and abscission in peaches in a manner similar to the action of naphthaleneacetic acid on apples[4]. Whether the primary effect of N-1-naphthyl phthalamic acid is on the endosperm, embryo or some other tissue is still to be determined. While little difference in the size of the fruits and ovules was found in these lots of adhering and abscising fruits treated with N-1-naphthyl phthalamic acid, larger differences were found in the auxin content and in the histological appearance of the embryo and endosperm of each lot of ovules (Table 1). The difference in auxin content of adhering and abscising ovules corresponds to Luckwill's report of lower auxin content in naturally dropping fruits of apples than in adhering fruits[5].

Presence of Gibberellin-like Substances in Lettuce Seed

GIBBERELLINS and gibberellin-like substances are being shown to occur in an increasing number of higher plants. Immature seeds of numerous species contain particularly large amounts of these substances[1], but the levels in mature seeds of the same species are much lower[2]. Certain seeds respond very strongly to applied gibberellin, this being particularly evident in certain 'light-requiring' seeds, for example, those of lettuce[3,4] and *Arabidopsis thaliana*[5], in which gibberellin treatment may result in complete germination in the dark. The obvious first step towards understanding the physiological significance of this gibberellin action is to determine whether gibberellin-responsive seeds contain endogenous, gibberellin-like growth regulators. The present communication reports on such studies with mature seeds of lettuce (*Lactuca sativa* L.).

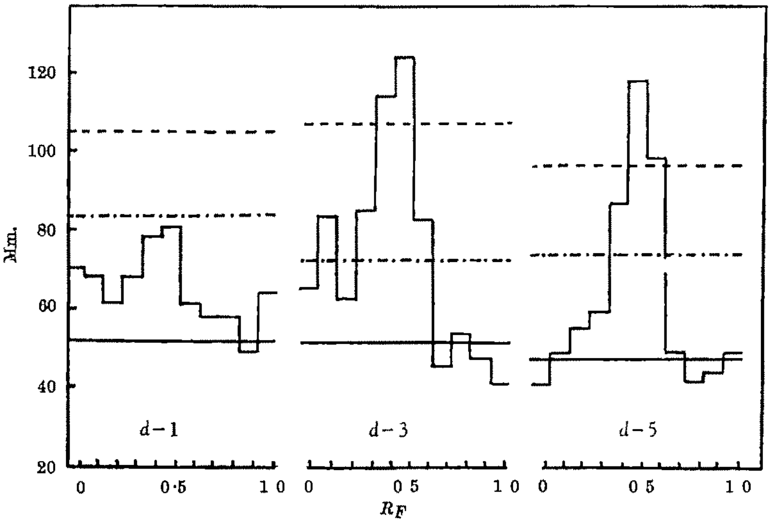

Fig. 1. Histogram of extracts from dry seeds of lettuce, tested for gibberellin-like activity on *d*-1, *d*-3 and *d*-5 dwarf maize. Each test plant was treated with a quantity of extract equivalent to 50 gm. of dry seed. Abscissa, R_F values; ordinate, sum of lengths of first and second leaf sheaths of test plants. ———, Untreated controls; – – – –, 0 01 µgm. gibberellin A_3; -·-·-·-, 0 1 µgm. gibberellin A_3. R_F value of gibberellin A_3, 0 6

The seed used was of the Grand Rapids variety, obtained locally and possessing a pronounced light requirement (at 26°, dark germination about 10 per cent; germination after saturation irradiation with white or red light 95–100 per cent).

The extraction method was that of West and Phinney[6] with some minor modifications; it is largely identical with that used by one of us[7] in similar work with vegetative and photoperiodically induced plants of *Hyoscyamus niger*.

The assay was performed on three monogenic dwarf mutants of maize (*Zea mays* L.), *d*-1, *d*-3 and *d*-5 (ref. 9). The use of these mutants as assay material is essential since their response is highly specific for gibberellins and furthermore permits the recognition not only of quantitative, but also of qualitative, differences in the activities of different gibberellins and gibberellin-like materials. Thus, gibberellins A_1, A_2 and A_3 and numerous gibberellin-like materials from various plants are highly active on all three mutants, but another gibberellin-like material, bean-factor II (ref. 6), probably identical with gibberellin A_5 (ref. 10), while highly active on *d*-3 and *d*-5, is only 5 per cent as active as gibberellin A_3 on *d*-1.

Altogether, three experiments were performed, giving highly consistent results. A representative histogram is shown in Fig. 1. It is evident that there is a zone of pronounced gibberellin-like activity in the R_F region of 0·3–0·6, with a maximum at 0·4–0·5. Furthermore, this activity is much more pronounced on the *d*-3 and *d*-5 mutants than in the *d*-1 test; thus the active material in the extracts shows the activity pattern of bean factor II and not of gibberellins A_1, A_2 and A_3. Some indications of activity were also found in other regions of the chromatograms (for example, at $R_F = 0·1$ on the *d*-3 mutant in Fig. 1); these, however, varied between experiments and thus require further study.

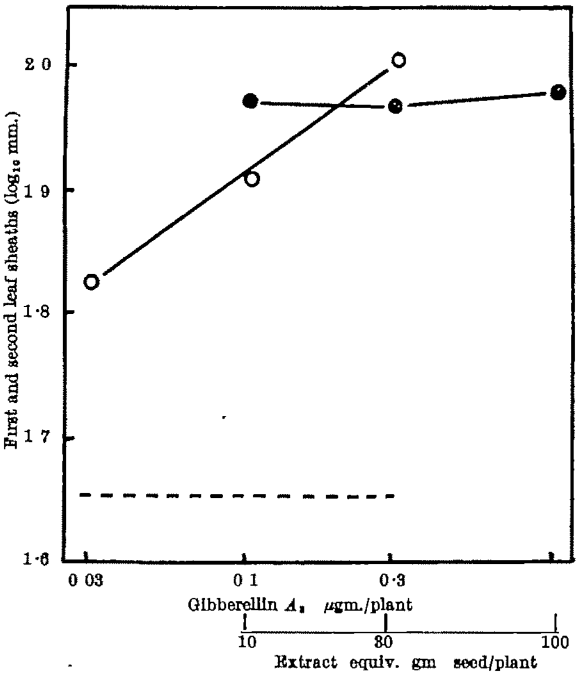

Fig. 2. Growth response of *d*-3 maize seedlings treated with different amounts of gibberellin A_3 (○——○) and of extract from dry lettuce seed (●——●). Broken line, untreated controls

Fig. 2 shows an attempt at a quantitative estimation of the amount of active material. For this experiment, the active zones of the chromatogram shown in Fig. 1 were re-extracted with acetone and the response of *d*-3 mutant seedlings to this extract was compared with their response to different amounts of gibberellin A_3. The response of the seedlings to 0·03 μgm. to 0·3 μgm. of gibberellin A_3 per plant, when plotted as logarithm of growth against the logarithm of dose, follows a straight line, as is characteristic of the dwarf-maize assay in the range of approximately 0·003–3·0 μgm. gibberellin per plant[9]. However, varying amounts of extract, corresponding to 10, 30 and 100 gm. of the original seed weight, all produced responses of practically equal magnitude. This fact indicates that the extracts still contained materials which, with increasing amounts, reduced the response of the plants. Therefore, precise estimations of the quantity of active material are not yet feasible; however, it can be assumed from Fig. 2 that the minimum level is in the order of 0·1–0·3 μgm. per 10 gm. of seeds or 10–30 μgm. per kgm., expressed as equivalents to gibberellin A_3.

It is thus clear that dry lettuce seeds contain gibberellin-like, endogenous growth substances which are physiologically related to bean-factor II and the quantities of which seem to surpass considerably the values reported for other mature seeds[8], although they still seem to be below the levels of activity found in immature seeds.

Gibberellin-like activity was also found in imbibed seeds. It is planned to pursue this matter further, and in particular, to study the gibberellin content in relation to germination.

This work was performed while one of us (A. L.) was on sabbatical leave from the University of California, Los Angeles, and holder of a senior post-doctoral fellowship from the National Science Foundation, Washington, D.C. He wishes to thank the staff of the Hebrew University's Botany Department and its chairman, Prof. M. Evenari, for their hospitality. We are greatly indebted to Dr. B. O. Phinney, University of California, Los Angeles, for supplying seeds of the three maize mutants.

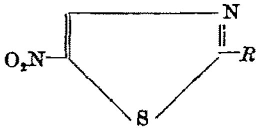
MICROBIOLOGY

Specific Inhibition of Obligate Anaerobes

MANY drugs are known which optimally inhibit single groups of micro-organisms (bacteria, fungi, or protozoa), or which inhibit specific types within one of these groups (Gram-positive or Gram-negative bacteria, pathogenic or non-pathogenic fungi). For example, certain antibiotics only inhibit bacteria; the polyene antibiotics only inhibit fungi; fumagillin inhibits protozoa[1]. This list can be extended to include compounds other than antibiotics: crystal violet (Gram-positive bacteria), sodium azide (Gram-negative bacteria). These compounds, possessing taxonomic specificity, are clearly contrasted with non-specific antimicrobial agents such as the halogens, phenols, and quaternary ammonium compounds.

I am concerned here with an antimicrobial activity which appears to transcend major taxonomic boundaries in an unusual fashion. Compounds of the type,



where *R* is a substituted amino group, are selective inhibitors of obligate anaerobes. In particular, I wish to report on the activity of an acetylated piperazine derivative, 1-(5-nitro-2-thiazolyl)-4-acetyl piperazine[2]. Susceptible anaerobes include Gram-positive and Gram-negative bacteria, actinomycetes, and protozoa, but not their aerobic counterparts. This activity may be regarded as a special kind of physiological specificity, which does not appear to have been reported.

All determinations of antimicrobial activity were made under growth conditions optimal for the organ-

Table 1. MINIMUM CONCENTRATIONS OF 1-(5-NITRO-2-THIAZOLYL)-4-ACETYL PIPERAZINE TO INHIBIT THE GROWTH OF ANAEROBIC AND AEROBIC MICRO-ORGANISMS

† Engel's porphyrinless mutant of this parent strain sensitive at 111 μgm./ml. (see text).

ism studied. Anaerobic bacteria and *Lactobacillus casei* were grown in Brewer's thioglycollate broth ('Difco') supplemented with 10 per cent of rabbit serum when necessary; trichomonads in Kupferberg's simplified trypticase serum broth; trypanosomes in Diamond's blood broth[3]; *Euglena gracilis* under artificial illumination in acetate–peptone–yeast extract broth; *Desulphovibrio desulphuricans* in Van Delden's broth[4]; and *Leptospira icterohaemorrhagiae* in a semi-solid beef extract–rabbit serum medium. The slime mould *Physarum polycephalum*, maintained in the plasmodial 'animal' phase, was grown on 1·0 per cent oat-meal agar. Malignant human epithelial cells, strain HeLa (Gey), were grown on glass in Hank's balanced salt solution, *p*H 7·0, supplemented with lactalbumin hydrolysate (0·5 per cent), yeast extract (0·1 per cent), calf serum (10 per cent), penicillin (50 units per ml.), and streptomycin (50 μgm. per ml.).

The activity of the piperazine drug is shown in Table 1. The aerobic and facultative organisms were approximately 300–1,000 times more resistant to the drug than the obligate anaerobes, regardless of taxonomic status. When inhibition of an aerobe did occur, as with *Physarum*, *Salmonella*, *Escherichia*, *Leptospira* and strain HeLa cells, a relatively high concentration of drug was required. It is difficult, of course, to state where sensitivity ends and resistance begins, but the broad outline of aerobic resistance and anaerobic sensitivity is apparent. The anomalous response of our strain of *Clostridium perfringens* (250 μgm./ml. for inhibition) suggests further experiments to determine if shifts of susceptibility can occur in a continuously exposed population.

The effect of 1-(5-nitro-2-thiazolyl)-4-acetyl piperazine is microbicidal, since exposed populations are rendered sterile within 24 hr. at the minimum inhibitory concentrations stated. Activity against susceptible anaerobes is independent of *p*H, exogenous protein, and cannot be reversed by twenty times the concentration (on a molar basis) of thiamine, riboflavin, biotin, calcium-D-pantothenate, nicotinamide, pyridoxamine, folic acid, inositol, guanine, adenine, xanthine, hypoxanthine, thymine, or uracil.

An experiment was conducted to determine if the selective inhibition of obligate anaerobes was related to anaerobiosis *per se*, that is, to a sensitivity potentiated by the environment. If this were so, anaerobic growth of the facultative organisms studied (*Staphylococcus aureus*, *Streptococcus faecalis*, *Escherichia coli*, *Shigella dysenteriae*, and *Candida albicans*) might induce sensitivity to this drug. This was not the case. These organisms, grown anaerobically in nutrient broth (alkaline pyrogallol technique), displayed their usual resistance to the piperazine drug.

As indicated in Table 1, a porphyrinless mutant of *Escherichia coli*[5], kindly supplied by Dr. M. S. Engel, of the Oak Ridge National Laboratory, was examined for susceptibility to the piperazine drug. The mutant, capable of growth and respiration with or without exogenous hæm, was ten times more sensitive to this drug than the parent strain. With another member of the nitrothiazole series (R = acetamido) the difference was more striking: inhibition of the parent strain at 250 μgm. per ml., total inhibition of the mutant at less than 1·0 μgm./ml.

An attempt was made to induce sensitivity in the above-mentioned facultative organisms by blocking hæm pigments with potassium cyanide. When these organisms were grown in the presence of the highest concentration of cyanide compatible with growth ($2–10 \times 10^{-3}$ *M* at *p*H 7·2), the usual resistance to the piperazine drug was encountered. Therefore, chemical inactivation of hæm was not equivalent to loss of hæm by mutation.

It should be pointed out that *Desulphovibrio desulphuricans*, which possesses a reversibly oxidizable pigment[6] similar to cytochrome c_3, was as sensitive as anaerobes totally devoid of such pigments (for example, *Clostridium novyi*, *Trichomonas vaginalis*). There is apparently something more fundamental to poisoning by 1-(5-nitro-2-thiazolyl)-4 acetyl piperazine (and perhaps to anaerobiosis) than mere absence or presence of hæm.

In addition to this unique *in vitro* activity, the piperazine drug was effective as an oral trichomonacide in mice. Albino males, carefully screened to weigh 12–15 gm., were infected intraperitoneally with 3×10^6 cells from a 48-hr. culture of *Trichomonas foetus*. Untreated control mice showed 100 per cent mortality usually within 10 days (severe abdominal distension with marked peritonitis). Mice treated once orally with 80 mgm./kgm. of the piperazine drug (3½ min. after infection) showed 100 per cent survival. The acute oral *LD*50 in mice was 1,200 mgm./kgm.; the 50 per cent curative dose (*CD*50) for orally treated mice was about 48 mgm./kgm. of body-weight, as calculated in a dose–response study by the method of Litchfield and Wilcoxin[7]. Further chemotherapeutic studies in animals and man seem warranted, not only for trichomoniasis, but also, indeed, for any infection produced by an obligate anaerobe (for example, amœbic, spirochætal, and clostridial infections).

Compounds of the type described should also prove invaluable in studies designed to elucidate the mechanism of anaerobic growth. Extrapolations and excursions into anaerobiosis in mammalian cells may prove interesting.

I wish to thank Dr. David B. Reisner for supplying the nitrothiazolyl piperazine, for suggesting its antimicrobial evaluation, and for his advice and encour-

agement. The technical assistance of Mr. Harry Jones is gratefully acknowledged.

BACTERIOLOGY

Physiology of D-Glutamic Acid-requiring Mutants of *Bacillus subtilis*

As reported in a previous paper[1], the *3d* mutant of *Bacillus subtilis K* requires either D-glutamic acid, D-aspartic acid or D-alanine for growth, and the *3a* mutant either D-glutamic acid, D-aspartic acid, L-glutamic acid or L-aspartic acid. This communication is concerned with the cell physiology of these mutants in a medium devoid of D-glutamic acid.

Three media were employed. Minimal medium (*MM*) was prepared as prescribed by Gray and Tatum (L-asparagine was eliminated). The medium lacking the nitrogen components (ammonium chloride and ammonium nitrate) of Gray and Tatum's prescription was termed the *M–N* medium, and the minimal medium supplemented with 100 μgm./ml. of D-glutamic acid the *DG* medium. Cells were precultivated in the supplemented medium for 15 hr. at 30°, and after centrifugation and washing, each 0·1 ml. of the cell suspension was inoculated into 10 ml. of *MM*, *M–N* and *DG* media. Cultivation was in Monod tubes on a shaking machine at 37°.

Fig. 1 (I) shows growth-curves of strain *3d*. The number of viable cells in *MM* medium increased for a while and, after a lapse of 7 hr., decreased rapidly. It was supposed that the rapid lysis observed might have been induced by the unbalanced reproduction between cell wall and cytoplasm. If D-glutamic acid were an essential component of the cell wall, the latter would not be reproduced under the existing conditions, while, because the system concerning the biosynthesis of L-glutamic acid ought to be active in this strain, reproduction of cytoplasm would proceed independently. The residual growth observed in an earlier period of cultivation might be due to the free D-glutamic acid present in the inoculum. This assumption is consistent with the results in Fig. 1 (II), which shows the growth-curves of strain *3a*. It is reasonable that no significant residual growth is observed in *MM* medium, because the biosynthetic pathway of both D- and L-glutamic acids is equally blocked in this strain.

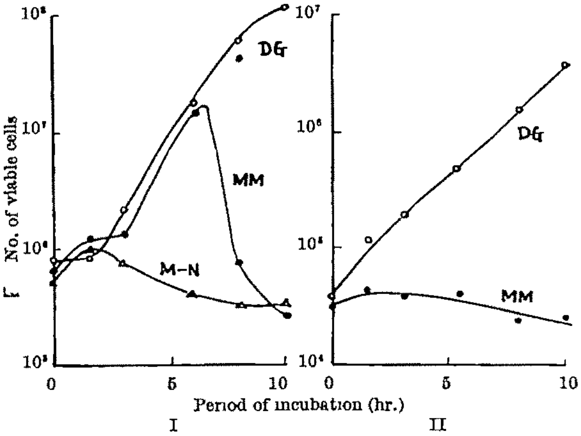

Fig. 1. Growth curves of strains *3d* (I) and *3a* (II) in *MM*, *M–N* and *DG* media

D-Glutamic acid in cell walls was identified as follows: First, washed cells of *Bacillus subtilis K* were ground in a mortar with fine glass beads, and then the cell wall fraction was separated from other parts by differential centrifugation. The sample was washed with sodium chloride solution (1 *M*) and water repeatedly, and 50 mgm. of the dried material was hydrolysed in 5 ml. of 3 *N* hydrochloric acid for 20 hr. at 110°. A small portion of the residue after evaporation was developed on a paper using a mixture of butanol, acetic acid and water (4 : 1 : 2) as solvent. Glutamic acid (D- or L-) was extracted from the corresponding portion of the paper, and added to *MM* medium to test whether strain *3d* could grow in this supplemented medium. As was expected, the strain grew well in the medium. Meanwhile, no growth of the strain *3d* was observed in the *MM* medium supplemented with glutamic acid (D- or L-) from protoplasts of the same bacterium. The protoplasts were prepared by treatment with lysozyme. It is concluded, therefore, that a detectable amount of D-glutamic acid is contained in the cell wall of this bacterium but not in the cytoplasm.

The phenomenon observed above is very similar to that found in diaminopimelic acid-requiring mutant of *E. coli*[2], and, probably, to the lysis of *E. coli* by penicillin treatment[3].

Effects of Chloramphenicol on the Recovery of Ultra-violet-irradiated *Escherichia coli B*

Doudney[1] has recently shown that the addition of chloramphenicol immediately following the ultra-violet irradiation of *Escherichia coli B* prevents the recovery of the bacteria as indicated by the decrease in viable count, whereas such an addition made after 40 min. incubation with or without nitrogen source, like an incubation in nitrogen-free medium, markedly enhances the recovery. On the basis of these and other pertinent observations, Doudney presented the idea that the synthesis of ribonucleic acid and protein, as required for the resumption of deoxyribonucleic acid synthesis following the temporary inhibition thereof caused by ultra-violet light, and the prevention of subsequent unbalanced growth[2] by inhibiting the synthesis of protein and ribonucleic acid are necessary conditions for the recovery of ultra-violet-irradiated bacteria. Experiments of similar nature made by us, however, do not seem to support such a view.

According to Aronson and Spiegelman[3], the lower concentration of chloramphenicol (20 μgm./ml.) as used by Doudney might be insufficient to block the protein synthesis completely, leading to a different response of bacteria from that observed with higher concentrations of the antibiotic in certain aspects of bacterial physiology. In our experiments a higher concentration (100 μgm./ml.) was employed unless otherwise stated. Further, Doudney used a rather heavy dose of ultra-violet light which reduced the viable count of strain *B* by a factor of more than 10^4. Under such conditions, the recovery of bacteria in a nitrogen-free medium showed a lag of 40 min. or more[1,4]. This agrees with our own observation reported elsewhere[5]. However, even with such a high ultra-violet dose, chloramphenicol added to nitrogen-free medium (0·1 *M* phosphate buffer (*p*H 7·0) – 0 02 *M* glucose) immediately following the irradiation promoted a marked recovery without a noticeable lag, although in *tris*–glucose–salt–casamino acid medium[5] the antibiotic induced the recovery to a smaller extent and with a lag of about 40 min. during which the viable count decreased slightly[5].

When we used a smaller dose of ultra-violet light to yield a survival ratio of around 10^{-3} the recovery in nitrogen-free medium started without delay and chloramphenicol did not significantly affect such a recovery (Fig. 1*B*). Under such conditions of irradiation, chloramphenicol added to *tris*–glucose–salt–casamino acid medium immediately following the irradiation also gave rise to a bacterial recovery without delay, although the recovery was more pronounced when the antibiotic was added after 40 min. incubation in *tris*–glucose–salt–casamino acid medium[5]. That such was not due to the higher concentration of chloramphenicol is illustrated in Fig. 1*A*, in which 20 μgm./ml. of the antibiotic, the concentration employed by Doudney, was also effective in promoting the recovery without lag even when added at 0 min. of incubation. It should be noted that in experiments shown in Fig. 1, the recovery of bacteria in nitrogen-free medium and in growth medium with chloramphenicol followed different kinetics, indicating some difference in the mechanism involved.

The synthesis of deoxyribonucleic acid in our lightly irradiated bacteria showed a lag of about 40 min. in *tris*–glucose–salt–casamino acid medium, while those of ribonucleic acid and protein started without delay, and chloramphenicol added at 0 or 40 min. of incubation, as observed by other workers[1,6] with lower concentrations of the antibiotic, completely inhibited or allowed to a certain extent, respectively, the resumption of deoxyribonucleic acid synthesis.

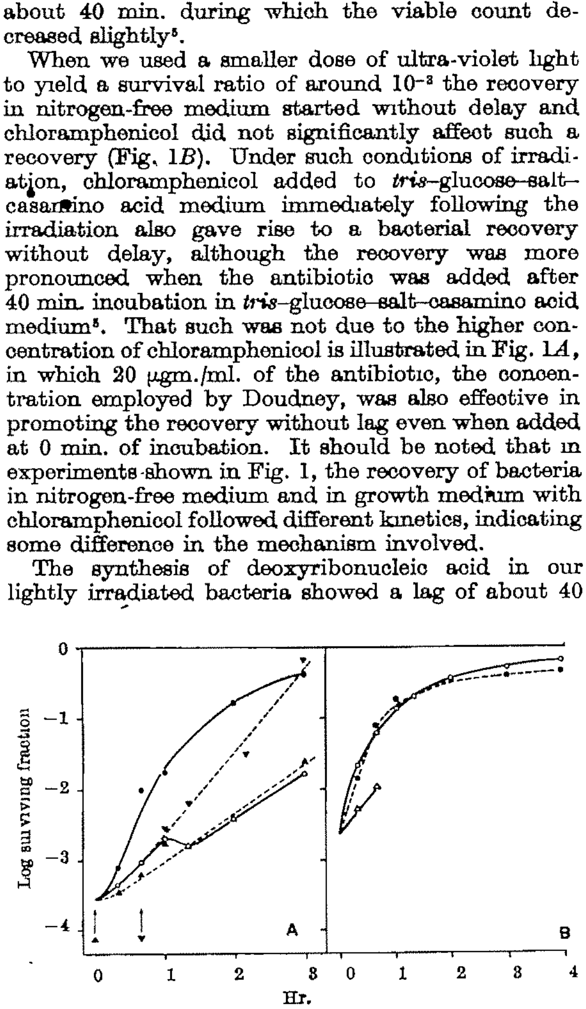

Fig. 1. Recovery of ultra-violet-irradiated *Escherichi coli B* in different media. Bacteria in late logarithmic phase of growth in *tris*–glucose–salt–casamino acid medium were irradiated for 30 sec. at 1 m. distance from Toshiba germicidal lamp (15 W.). *A*. Irradiated bacteria were shaken in *tris*–glucose–salt–casamino acid medium at 37° C. (—○—), with 20 μgm./ml. of chloramphenicol added to it immediately following irradiation (– –▲– – –) or after 40-min. incubation (– –▼– –) as shown by the arrows, or in 0·1 *M* phosphate buffer (*p*H 7 0) + 0 02 *M* glucose (—●—). *B*. They were shaken in 0·1 *M* phosphate buffer (*p*H 7·0) + 0·02 *M* glucose with (– – ● – –) and without (—○—) 100 μgm./ml. of chloramphenicol, or in *tris*–glucose–salt–casamino acid medium (—△—)

The discrepancy between Doudney's and our own observations may be due partly or entirely to the slight difference in experimental conditions or in the strain used. However, our experiments clearly indicate that the inhibition by chloramphenicol of the resumption of deoxyribonucleic acid synthesis does not necessarily prevent the recovery of ultra-violet-irradiated bacteria, and this may be sufficient evidence for ruling out the possibility suggested by Doudney[1]. It was also demonstrated[7] that the unbalanced growth could not be taken as the cause of bacterial death either in thymine-deficient, ultra-violet-irradiated, or mustard-treated *E. coli*. Thus, the possible mechanism of the recovery of ultra-violet-irradiated *E. coli B* is still open to question.

An Association between Capsulation and Phage Sensitivity in *Erwinia amylovora*

DURING a recent outbreak of fire blight in Britain[1,2] more than 150 isolations of the pathogen, *Erwinia amylovora*, have been made in this laboratory. On initial plating of infected material two types of colony are often observed[3]. The dominant type has characteristic markings on 'Yeastrel' peptone agar plates incubated at 30° C. For convenience, strains which form this type of colony are called 'typical'; those forming the second type of colony, which is relatively featureless, and less opaque, are called 'atypical'. Some strains are intermediate in character, even after re-streaking several times. With some such strains the opacity of individual colonies on a single streak plate may show considerable variation, with others, each individual colony appears mottled; marking may or may not be apparent on the more opaque colonies. Some 'typical' strains regularly yield a small proportion of unmarked colonies.

Using the wet indian ink method with a phase-contrast microscope, it was observed that the majority of cells of the 'typical' strains had small but distinct capsules when grown on either 'Yeastrel' peptone agar or a phage-test medium containing 1 per cent glycerol[3]. In contrast, some of the 'atypical' strains showed no capsules (Table 1). The remaining strains showed varying proportions of capsulated and non-capsulated cells. An accurate

Table 1. Colony Form, Capsulation and Phage Sensitivity of 28 Strains of *Erwinia amylovora*

Form of colony at 30° C. on 'Yeastrel' agar	No. of strains	Proportion of capsulated cells	Sensitivity to phages	
			4L and *4S*	23
Typical	2	majority	*Ch*	—
Typical	4	majority	*Ch*	(*c*)
Intermediate	2	many	*Ch*	*C*
Intermediate	1	many	*ch*	*c*
Intermediate	8	few to many	*ch*	*C*
Atypical	4	few to many	*ch*	*C*
Atypical	1	rare	(*c*)*h*	*C*
Atypical	1	few	—	*C*
Atypical	8	rare	—	*C*
Atypical	2	none	—	*C*

Key: *C*, confluent lysis, little background turbidity; *c*, moderate background turbidity; (*c*) heavy background turbidity; *h*, halo

assessment was not possible with this method, because non-capsulated cells tended to clump in the indian ink though they were not agglutinated in normal saline. Also, some intermediate 'atypical' strains showed varying proportions on different occasions. An approximate estimate of the degree of capsulation of each strain was made and the results of two observations were recorded as follows in Table 1: majority (> 75 per cent), many (25–75 per cent); few (< 25 per cent); rare (< 1 per cent).

Crosse[1] has reported the isolation of phages which lyse *E. amylovora*. Since then, further phages have been isolated in this laboratory using the technique described by Crosse and Hingorani[3,4]. Two of these, *4S* and *4L*, give large (about 3·0 mm.) and small plaques (about 1·0 mm.) respectively on 'typical' strains. A third gives small plaques on 'atypical' strains.

The relationship between colony characteristics at 30° C., degree of capsulation and phage sensitivity with 28 strains is shown in Table 1. At one extreme there are the so-called 'typical' strains, the majority of the cells of which appear capsulated. These are lysed by phages *4L* and *4S*, which produce confluent lysis with a little background turbidity; the lysed area is surrounded by a distinct halo which extends on continued incubation. 'Typical' strains are not normally lysed by phage 23 or, if lysis is observed, it is largely obscured by background turbidity. At the other end of the scale are some of the stable 'atypical' strains which appear virtually non-capsulated or which at the most have rare capsulated cells. They are not lysed by phages *4L* and *4S*, but are strongly lysed by phage 23. Various intermediate reactions which have been observed with the remaining strains are also shown. Like capsulation, the reactions may vary slightly from one experiment to another, but the general picture remains the same.

It would appear from these observations that sensitivity to phages *4L* and *4S* depends on the presence of capsules and to phage 23 on the absence of capsules, and that where the culture contains a mixture of capsulated and non-capsulated cells some reaction with both phages can be expected. The strength of the reaction would seem to depend on the relative proportions of each; whether or not lysogenization occurs has not yet been fully investigated. Similar observations have been made by Rakieten, Eggerth and Rakieten[5] with mucoid strains of *Klebsiella, Escherichia* and *Aerobacter*. They found that phages acting on the mucoid strains were mainly type- or strain-specific. In my experience with *E. amylovora*, all strains giving 'typical' colonies (more than 130), whether isolated from *Pyrus, Crataegus, Sorbus* or *Cotoneaster* spp., also two strains in the National Collection of Plant Pathogens (100 and 311), have been sensitive to phages *4S* and *4L*.

The presence of extending halos in the case of reactions with phages *4L* and *4S* and capsulated strains suggests that an enzyme capable of hydrolysing capsules is produced[6,7].

VIROLOGY

Filamentous Structures in Ectromelia Virus-infected Cells

The presence of parallel arrays of thin lamellæ clustered in bundles in the cytoplasm of some tumour cells containing Shope fibroma virus has been depicted by Bernhard *et al.*[1]. Fawcett[2] has observed irregular, coarse bundles of dense filaments in the cytoplasm of virus-containing tumour cells of the Lucké renal adenocarcinoma. Morgan *et al.*[3], reviewing their earlier micrographs of chick chorioallantois infected with fowl pox, found clusters of dense filaments, indistinguishable from those described by Bernhard, in the cytoplasm of ectodermal cells containing virus particles[4]. More recently, Reczko[5] has demonstrated the presence of groups of lamellæ in the epithelial cells of guinea pig peritoneum infected with swine pox virus. In electron micrographs of sections of chick chorioallantoic membranes infected with ectromelia virus, bundles of filaments have been observed in association with intra-cytoplasmic virus inclusion bodies.

Chorioallantoic membranes of 10-day-old White Leghorn embryos were inoculated[6] with a suspension of ectromelia virus so diluted as to give semiconfluent lesions after 72-hr. incubation at 36° C. The inoculum was second-egg passage material derived from infected mouse spleen originally received from Dr. W. C. Cutting of Stanford University. After incubation for 72 hr., membranes were fixed for about 5 min. while still in the eggs with buffered 1 per cent osmium tetroxide containing sucrose[7]. Membranes were excised and fixation continued for another 60 min. Ultra-thin sections of methacrylate-embedded tissue were examined with an RCA *EMU 2-B* electron microscope.

An infected mesodermal cell depicted in Fig. 1 shows a bundle of filaments with discrete virus particles interposed between it and a large virus inclusion body. A portion of the nucleus is seen in the lower left corner. Fig. 2 is a higher magnification showing in greater detail the fine structure of the filaments. The thickness of filaments is 8 mμ on the average, while the length is about 3–4μ. Virus forms, 265 × 200 mμ, with dense inner bodies lie between the bundle of filaments and inclusion body,

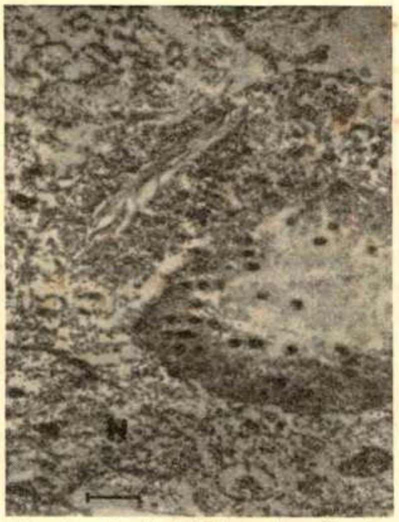

Fig. 1. Mesodermal cell of 72-hr. ectromelia virus-infected chorioallantois. A mitochondrion in a degenerative stage is seen immediately to the right of the nucleus (*N*). The filament bundle appears at the upper left. (In both Figs. 1 and 2, the scale mark represents 1μ.) (× *c*. 7,300)

the periphery of which is shown in the lower right corner.

In the numerous sections studied the filaments have generally been observed to be, at least topographically, in close association with virus forms and with inclusion bodies. In the case of Shope fibroma, the filaments, 7 mμ in diameter, were noted to be closely associated with cytoplasmic masses of virus or precursors of virus and were interpreted as possible by-products of a lipid nature of virus metabolism[1]. Fawcett observed typical virus particles contiguous to the filaments and believed that these might be related in some obscure way[2]. Reczko, noting the consistent location of these formations in the vicinity of developmental forms of the virus in the early stages of infection, concluded that these were probably connected with the process of virus synthesis[5].

The role of these filaments in virus development has not been established. Their presence in the cytoplasm of virus-infected cells has thus far been described for only the five aforementioned agents. It is possible that on careful study these structures will be observed in cells infected with other viruses[8]. Whether they be by-products of virus metabolism, pathological cellular responses to virus invasion, or stages in virus reproduction, will have to await further and more extensive investigation.

An Indicator Plaque-forming System for Demonstration of Interference by Non-cytocidal Strains of Rabies Virus

FIXED strains of rabies virus are known to multiply in chick embryo tissues[1,2]. So far, however, a cytocidal effect of the virus on monolayers of primary chick embryo cell cultures has not been observed. Since chick embryo-adapted strains of rabies virus interfere with infection by homologous virus in animal cells[3], the present investigations were undertaken to demonstrate interference of rabies virus with a superimposed infection of western equine encephalitis virus, which is known to produce cytopathic changes in these cultures.

Monolayers of chick embryo cells in 60-ml. Petri dishes were exposed for 2 hr. to $10^{6\cdot2}$ mouse *LD*50's of a fixed (*CVS*) strain of rabies virus in 0·2 ml. inoculum. 5 ml. of Eagle–Earle's medium were then added and the plates incubated at 37° C. for 24 hr. in an atmosphere of about 5 per cent carbon dioxide. The medium was discarded and the cells were exposed for 45 min. at 37° C. to western equine encephalitis virus. The plates, overlaid with neutral agar, were then incubated for 72 hr., and the cell sheets stained with a 1 : 10,000 solution of neutral red for the plaque count. Complete inhibition was observed of plaque formation by western equine encephalitis virus up to 2 million plaque-forming units, the highest concentration used. Essentially the same results were reproducible on repeated tests. In a preliminary study street virus also appeared to interfere with western equine encephalitis in the same system.

Quantitative studies of the rabies virus with the western equine encephalitis indicator system described gave promising results. Increasing dilutions of rabies virus showed a consistent titration pattern in repeated tests. Table 1 illustrates typical results obtained in one of the tests. In this table it will be noted that the 1 : 5,000 dilution of rabies virus, equivalent to about $10^{3\cdot5}$ *LD*50 in 0·2 ml. inoculum, still interfered with western equine encephalitis.

Although preliminary experiments indicate that the rabies virus particle itself may interfere with subsequent infection of the cell with western equine

Table 1. INTERFERENCE PRODUCED BY FIXED RABIES VIRUS TO WESTERN EQUINE ENCEPHALITIS

Inoculum	No. of plaques per plate exposed to tenfold dilution of western equine encephalitis		
	10^{-1}	10^{-5}	10^{-6}
0·2 ml. of following dilutions of rabies virus* :			
1 : 1,250	0,0 (duplicate plates)	0,0	0,0
1 : 5,000	*D*†, *D*	27,10	4,9
1 : 20,000	*D*, *D*	104,137	31,23
Western equine encephalitis control	*D*	215,154	24,30

* Rabies virus inoculum undiluted contained $10^{7\cdot8}$ mouse *LD*50 per 0·2 ml.

† Degeneration of cells.

encephalitis, the interference can also be mediated in part by 'interferon' (as named by Isaacs and Lindermann[4]). This was demonstrated as follows. The culture medium covering the monolayer sheet exposed for 24 hr. to rabies virus was removed, centrifuged twice at 40,000*g* for 1½ hr., and the supernatant tested for absence of live virus by intracerebral inoculation into mice. This supernate, to which rabies antiserum was added to ensure neutralization of any residual live virus, was placed on fresh monolayers for 24 hr. The medium was then discarded and the cell sheets exposed to western equine encephalitis virus in the usual manner. Partial to complete inhibition of plaque formation by between 10 to 1,000 plaque-forming units of western equine encephalitis was obtained. This inhibition, however, was distinctly less than that observed with cell sheets directly exposed to rabies virus (Table 1).

The specificity of the test described was shown by neutralization of rabies virus with anti-rabies serum (Table 2). Increasing dilutions of anti-rabies serum against a constant amount of rabies virus displayed a titration pattern similar to that which occurred when serial dilutions of rabies virus alone were used as mentioned previously (Table 1).

Table 2. NEUTRALIZATION OF CONSTANT AMOUNT OF FIXED RABIES VIRUS WITH INCREASING DILUTIONS OF ANTI-RABIES SERUM

Inoculum	No. of plaques per plate exposed to dilution of western equine encephalitis		
	10^{-5}	10^{-6}	10^{-7}
0·1 ml. rabies virus* + 0·1 ml. serum to given final serum dilution :			
1 : 2	44,54	3,5	0
1 : 20	81,92	9,18	1
1 : 200	88,84	18,6	0
1 : 2,000	0,0	0,0	0
Western equine encephalitis control	79,40	11,8	1,0

* Rabies virus inoculum contained $10^{7\cdot5}$ mouse *LD*50 per 0·1 ml. inoculum.

The sensitivity of the test compares favourably to that of the hæmagglutination test employed with myxoviruses. The ratio of the number of infective doses (egg *ID*50) per hæmagglutinating unit averages $10^{6\cdot8}$ for myxoviruses of high infectivity[5], as compared with $10^{3\cdot5}$ mouse *LD*50 of rabies virus being equivalent to approximately one interfering unit.

The results indicate the value of the interference system described for both quantitative and qualitative assays of a non-cytocidal virus and its specific antibody.

Distribution-Free Interpretation of Spray-Drop Data

SPRAY-DROP assay results do not always meet the Poisson-distribution test proposed by Williamson and Taylor[1], even though they may be valid and the sole product of expensive measurements. Williamson and Taylor have described an appropriate method for interpreting the spray-drop results obtained by the technique of Williams and Backus[2,3] for estimating the concentration of particles in a suspension. In this technique the unknown suspension is mixed with a suspension of polystyrene latex spheres in known concentration. The mixture is sprayed as a fine mist, and droplets are collected on specimen supports for examination by electron microscopy. For each droplet, the number of particles and the number of latex spheres observed are recorded. Counted for many droplets, these numbers constitute the raw data from which the concentration of particles in the unknown suspension is deduced.

A statistical analysis supplied by Williams and Backus was refined by Williamson and Taylor. This refinement included a test for the likelihood that the raw data represent samples from two Poisson-distributed populations, one for polystyrene latex spheres and one for the particles. If the raw data satisfy the Williamson and Taylor tests, and are free from induced variation arising from large variations in droplet size, then the ratio of the number of particles to the number of polystyrene latex spheres in the mixed suspension can be estimated from the ratio of the total particle-count in all droplets to the total count of polystyrene latex spheres in all droplets. The variance of this estimate can be calculated by the equation of Luria, Williams and Backus[4]. Lack of information on the precise distribution of the ratio precludes the possibility of using this variance to calculate a confidence interval. When data do contain variations induced by variation in droplet size, and do not satisfy the distribution test of Williamson and Taylor, distribution-free statistical methods may still be applied to obtain useful inferences about the concentration of particles in the unknown suspension. The use of order statistics is an appropriate distribution-free method in this instance. The following results, however, apply equally well to data which satisfy the requirements for the Williamson and Taylor analysis. In general, one would not expect the inferences of distribution-free analysis to be as precise as those obtained using the Williamson and Taylor analysis. The measure of central tendency is the median when distribution-free methods are used. The true population mean

Table 1

Drop No.	No. of particles (P)	No. of polystyrene latex spheres (PSL)	Ratio $\left(X = \frac{P}{PSL}\right)$	Order statistic
1	76	35	2·171	10
2	139	66	2·106	8
3	115	54	2·129	9
4	59	40	1·475	2
5	23	28	0·821	1
6	85	41	2·073	5
7	140	79	1·772	3
8	95	15	6·333	12
9	21	10	2·100	7
10	148	71	2·085	6
11	78	35	2·229	11
12	105	57	1·842	4

and median are equal only when the distribution is symmetrical.

Table 1 shows typical raw spray-drop data and the assignment of order statistics. The order statistics are simply integers assigned in increasing sequence to the calculated ratio X. Let n be the number of droplets the contents of which were counted. Let v be the true median of the population of possible ratios. Then the probability that the value of X with order statistic r is less than v, and the value of X with order statistic $n - r + 1$ is greater than v, can be calculated using equation 1:

$$(X_r < v < X_{n-r+1}) = \sum_{i=r}^{n-r} \frac{n!}{(n-i)!\,i!}\left(\frac{1}{2}\right)^n \qquad (1)$$

From this probability statement, confidence intervals for the median may be deduced. These confidence intervals are broader than those which might be obtained if the distribution of the ratio were known precisely. If needed, narrower confidence intervals for the same fiducial probabilities may be obtained by applying Fieller's theorem, which is discussed by Finney[6]. For much work in virus assay, confidence intervals based on equation 1 are sufficiently precise. Fig. 1 represents equation 1 in graphical form and shows, for each sample size, the value of r, which describes the confidence interval on the median.

To use Fig. 1, choose the line labelled with the required level of confidence. For the appropriate sample size, find r and compute $n - r + 1$. Locate the values of r and $n - r + 1$ in the column of order statistics assigned to the data. The data corresponding to these values represent the extremes of the confidence interval. For example, the median ratio for the data in Table 1 would have a 99 per cent confidence interval lying between 1·475 and 2·229 and a 95 per cent confidence interval between 1·772 and 2·171.

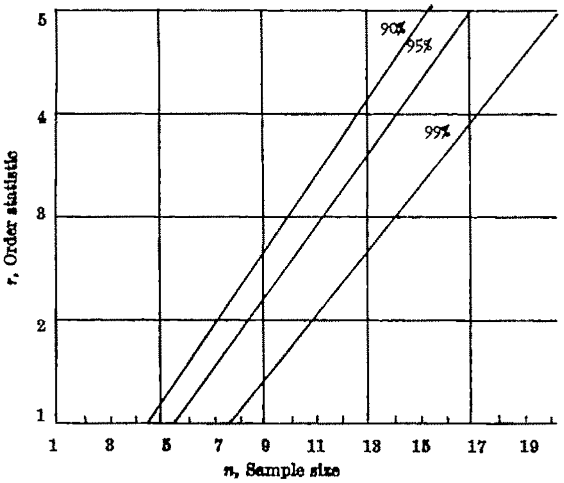

Fig. 1

When the underlying distributions for the data are certain, this information should be used in the analysis in order to discover any defects in the experimental technique, such as a bimodal distribution of drop-sizes. When order statistics alone are used in the analysis of spray-drop data, there is not the internal check for consistency provided by the Williamson and Taylor Poisson-distribution test. The distribution-free statistics are so convenient to use, however, that they can be recommended for broad application in situations where extreme precision in the estimate of the particle concentration is not required. The cost of this convenience may be the requirement for a better exercise of judgment in identifying valid data.

SOIL SCIENCE

Swelling of Calcium Montmorillonite

WARKENTIN *et al.*[1], following up earlier work of Schofield[2], Bolt and Miller[3], and others, showed that swelling pressures developed by suspensions of sodium montmorillonite on an ultra filter could be predicted satisfactorily from a diffuse ion layer model based on classical Gouy–Chapman theory. Warkentin *et al.* also reported results of preliminary experiments with calcium montmorillonite for which the same model appeared to be inappropriate. A significant result was the decrease in magnitude of reswelling observed as the peak pressure applied to the sample increased. They concluded that forces not taken into account in the calculation must be present. Recently, Aylmore and Quirk[4], Greacen[5] and others have published discussions of these results which may now require reconsideration in view of further studies of calcium montmorillonite swelling.

Blackmore[6], working with calcium-saturated clay, was unable to duplicate the results of Warkentin *et al.*, and as a consequence obtained and re-examined one of the samples used in that study. In Fig. 1 are given some results of compression–decompression measurements on the Warkentin *et al.* sample together with a replot of results from Warkentin *et al.* and corresponding results from a freshly prepared sample. In these curves, the half-spacing is calculated as the quotient of the specific water content by the specific surface, a convention which assumes equal spacing between all clay particles according to the model which was found to be successful for clays saturated with monovalent ions. Apart from a half-spacing displacement for curves obtained with the old and new samples, current measurements on these samples show very similar results and are consistent with more extensive results obtained by Blackmore, but the reswelling observed was less than half that reported by Warkentin *et al.*, except for samples which had experienced high pressures.

It was observed that the Warkentin *et al.* sample contained approximately 25 m.equiv. of sodium per 100 grams, due presumably to preparation by a calcium–resin column with insufficient free electrolyte[7]. This may account for the half-spacing displacement mentioned, but it apparently had little effect upon the magnitude of reswelling. No final solution of this anomaly has been achieved, but increasing evidence suggests that the swelling reported by Warkentin *et al.* is not that associated with a homoionic calcium montmorillonite.

Samples of calcium montmorillonite which had been equilibrated at various points in compression and decompression cycles were examined by X-ray diffraction and the presence of 18·8 Å. [001] spacings was demonstrated at all water contents and pressure equilibria. The average thickness of the 'packets' of particles presumed to be responsible for the diffraction peaks was estimated from the extent of line broadening. It was then possible to correct the swelling results for the presence of this 'condensed' phase and to estimate swelling between packets. It was also demonstrated that the exterior surface of the packets rather than residual single sheets not associated with packets was the active site of swelling.

Fig. 2 shows the original and corrected reswelling curves for a sample of calcium montmorillonite with 10^{-4} M electrolyte, and it is seen that agreement between the corrected curve and the curve obtained from the Gouy–Chapman model is surprisingly good. On the basis of this and related work it may be concluded that any swelling which occurs in a calcium clay–water system is largely of osmotic origin for the water contents studied, is a consequence of disorder within the sample, and can be approximated by calculations based on the Gouy–Chapman model.

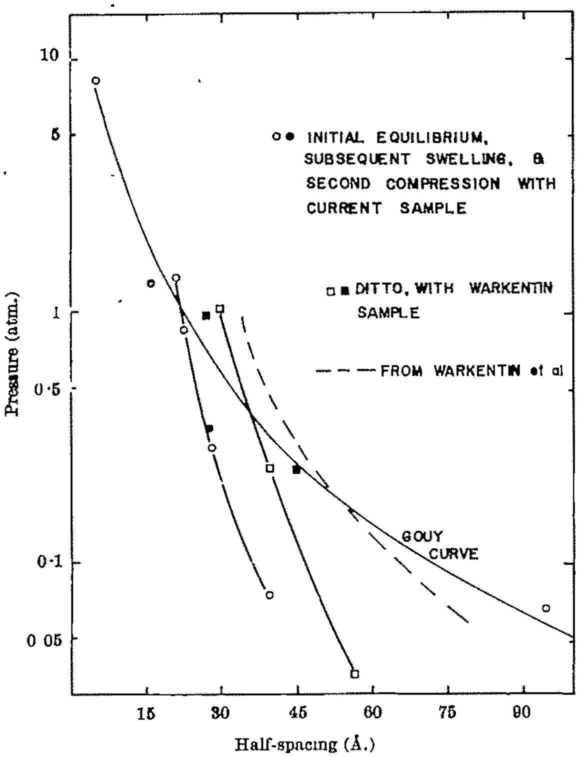

Fig. 1 Swelling pressure as a function of half-spacing for calcium montmorillonite with 10^{-4} M free electrolyte. Results are plotted for the theoretical curve, for a current sample, and for a repeat run with the sample used by Warkentin *et al.* in an earlier study, along with one of the re-swelling curves reported in this latter work

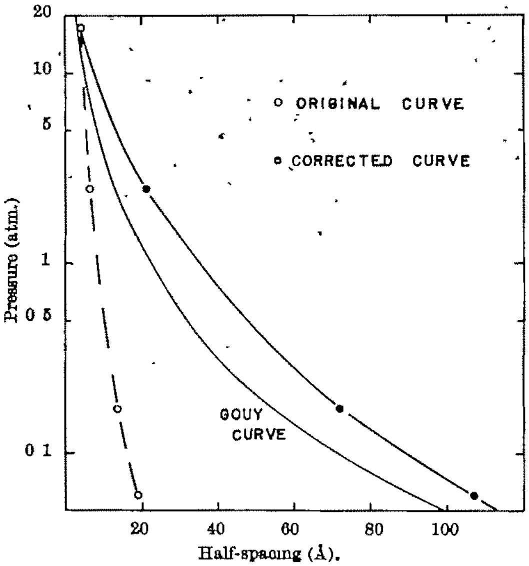

Fig. 2. Swelling pressures as a function of half-spacing for calcium montmorillonite calculated in the original form where half-spacing is obtained from total water and total surface area, and in the form corrected for 'packets' of unit sheets of clay. The average number of sheets per packet in this sample was 7, and the corrected curve has been displaced to the right by 3 Å. so that it will coincide with the uncorrected one at the point of maximum pressure

ANTHROPOLOGY

Apidium and *Oreopithecus*

IN view of attention recently directed to the taxonomic position of *Oreopithecus* among primates, as a result of new discoveries by Hürzeler[1] and Butler and Mills[2], a re-analysis of possible affinities of *Oreopithecus* with *Apidium*, from early Oligocene deposits of the Fayum, Egypt, seems desirable. Two fundamental points regarding this small Egyptian genus have been largely overlooked in recent literature on primate phylogeny. These are: first, that

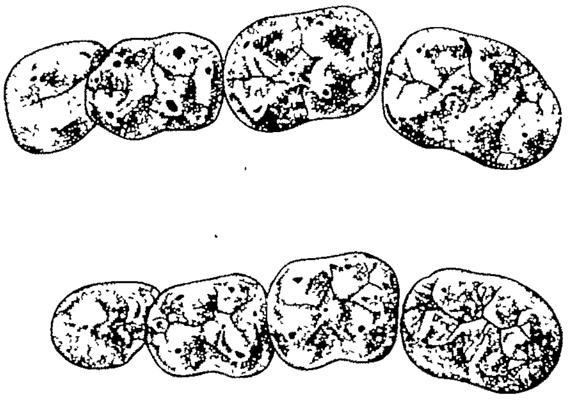

Fig. 1. Above, *Oreopithecus bambolii*, type; size approx. × 2 (after Hürzeler, ref. 1); below, *Apidium phiomense*, type; size approx. ×4. Apices of principal cusps indicated in black

ranking *Apidium* as a primate is still justifiable, and second, that (among primates) its greatest resemblances are to *Oreopithecus* (Fig. 1). As both these assessments depend on partly qualitative taxonomic judgments, either may continue to be debated. In the following account the bases for these two conclusions are briefly outlined.

Osborn's reluctance to designate an ordinal position for *Apidium* in his description[3] of the type and only specimen was understandable in 1908. Much less was then known of *Oreopithecus* dental patterns, and little or nothing had been published regarding a number of early Tertiary primates, with which *Apidium* can now be compared. Such forms, since discovered, include *Parapithecus* and *Propliopithecus*, both from the same Oligocene fluviomarine formation which yielded *Apidium*. Direct observation of the type-specimens of these three genera shows that they are possibly inter-related. Although the teeth of *Apidium* are more cuspidate than are those of the other two Fayum mandibles, substantial agreements obtain among all three in conformation of major molar cusps and in other details. The suggestion by Osborn that *Apidium* might be allied to *Cebochoerus*, a primitive suid of the late Eocene of Europe, was rejected by both Schlosser[4] and Gregory[5]. Even so, Osborn's caution evidently has seeded an unnecessarily persistent doubt that *Apidium* can be given an accurate assignment to an order. Actually, a sound assessment should be possible. The teeth preserved are complex and little worn, so that, together with details of the jaw ramus, the occurrence and morphology of a great many separate features can be noted. Gregory[5] held that *Apidium* represents a plausible structural progenitor for the cercopithecoids, an assessment which still has some merits. He also stressed its close dental similarity to *Oreopithecus*. Since the latter was then regarded as a cercopithecoid monkey correct assessment was further complicated. Recently, Piveteau[6] and Hurzeler[1] have suggested that *Apidium* is a condylarth related to *Phenacodus*, but this is improbable (see Simons, ref. 7).

Among non-primates the closest similarities with *Apidium* are still to be seen in *Cebochoerus*, rather than with any Condylarthra. Nevertheless, these correspondences also appear to be superficial. There are a large number of proposed species of *Cebochoerus*, some of which have very little resemblance to *Apidium*. A specimen of *Cebochoerus* sp. at Princeton University, No. 11472, from the late Eocene phosphorites of south-central France shows more features of agreement with *Apidium* than most members of the genus do. Yet their differences are significant. Although a small individual of *Cebochoerus*, this jaw is almost twice as large as that of the Fayum primate, and, unlike it, has a progressive increase in depth of the horizontal ramus posteriorly, a feature common in artiodactyls, but rare in primates. Moreover, the principal molar cusps of the suid are higher and occupy a more central position on the teeth than they have in *Apidium*. In the latter the antero-internal margin of the mandible starts to turn inward toward the symphysis next to $P_{\bar{4}}$, thus suggesting a reduced number of teeth in the front of the jaw (as in catarrhines) and unlike *Cebochoerus*, other artiodactyls, and Condylarthra generally. While third molar heels in both are large, that of *Apidium* lacks the distinct separation of the hypoconulid lobe of $M_{\bar{3}}$ seen in *Cebochoerus* and typical of Artiodactyla. A raised area or centroconid is present in molars of both forms under consideration, but as this structure also occurs in the same position in *Oreopithecus* it need not indicate a phyletic connexion between *Apidium* and *Cebochoerus*. This suid also differs from *Apidium* and *Oreopithecus* in having a more pronounced constriction between trigonid and talonid of $M_{\bar{1}-\bar{3}}$ and a distinct crest joining hypoconid and hypoconulid.

In spite of this evidence, it cannot be denied that convergence between some primates and some suids can be very deceptive. As late as 1951, the view that *Oreopithecus* might be a suid was advanced in print. A similar confusion of these two groups lay behind the description of "Hesperopithecus". Now that Hürzeler, through recent collecting in Italy, has performed the valuable service of making *Oreopithecus* one of the better-known fossil primates (in terms of skeletal parts represented) its ordinal position is no longer in doubt. This problem resolved, the primate status of *Apidium* is practically confirmed by way of the following observed similarities with *Oreopithecus*.

In *Oreopithecus* the fourth premolar, $P_{\bar{4}}$, is two-cusped, while at best in *Apidium* it is only incipiently so. It must be assumed, however, that at some point in the ancestry of *Oreopithecus* $P_{\bar{4}}$ had only one principal cusp, as is typical of Eocene and earlier primates. Moreover, the multiplication of cusps in the talonid region of $P_{\bar{4}}$ in *Apidium* is reminiscent of the condition here in *Oreopithecus* and in some Eocene primates as well. A small internal cusp also may be the homologue in the Fayum form of the inner cusp of $P_{\bar{4}}$ in *Oreopithecus*. Occasionally in the latter the internal cusp of the trigonid is somewhat smaller and lower than the outer, so that the bicuspedness is not developed to the same degree in all specimens of the Tuscan primate.

Agreement in structure in the first molar tooth, as between the two species, is striking. In both forms the basal cingulum is most distinct around the anterior end of the tooth. The two also agree in the position and shape of the paraconid element, and the protoconid and metaconid of both exhibit three major crests running down from their apices, two of these being directed more or less antero-internally and the third running postero-lingually. They are alike in having the central cusp or centroconid less distinct here than in $M_{\bar{3}}$, but differ from *Cebochoerus* in which this eminence is ridge-like instead of being low and rounded. Possible homologies of this cusp are of some interest. In *Apidium* and *Oreopithecus* the centroconid occupies a position at about the centre of a cross drawn through protoconid, metaconid, hypoconid and entoconid. Among primates such a shape and location of the centroconid is limited to these two forms. In some fossil mammals, including the condylarth *Phenacodus*, there is a subsidiary cusp on the antero-internal slope of the hypoconid which has been called a mesoconid. A slight prominence here is sometimes present in *Pliopithecus* and *Gigantopithecus*, but in them the cuspule never has a completely central position. It seems improbable that the structures here termed mesoconid and centroconid are homologous. If they are, then the centroconid must have arisen by 'slipping' toward a central position along the antero-internal crest of the hypoconid after an initial subdivision of the latter had occurred. That this could happen is doubtful. A preferable assumption may be that the centroconid arose in the *Apidium–Oreopithecus* branch of the hominoids as a neomorph, and is not to be equated with the mesoconid seen in phenacodonts, hyopsodonts and several other archaic mammalian families. In *Apidium* the $M\overline{1}$ talonid is somewhat broader compared to the trigonid than in *Oreopithecus*, but this is true only for the $M\overline{1}$; both differ from *Cebochoerus*, which has broader trigonids than talonids. A rather broad and flat hypoconulid in *Apidium* is suggestive of an earlier condition of development of the large area seen here in *Oreopithecus*; there is already some thickening of the posterior basal cingulum of the hypoconid which, by joining the hypoconulid area, could produce the broad posterior molar shelf of *Oreopithecus*.

In addition to similarities noted for the first molar which are largely repeated here, second molars of both show considerable reduction of the paraconid element, so that it consists only of an anteriorly bowed ridge or crescent between the apices of proto- and metaconids. Each exhibits a more distinct centroconid and elsewhere a slight mesostylid cuspule. As might be expected for an earlier form, in *Apidium* $M\overline{2}$ is slightly less specialized than in *Oreopithecus*, and also shows similarities with $M\overline{2}$ of *Pliopithecus*, and *Gigantopithecus*.

The third molar is the largest and longest of the molar series in both primates (although in *Apidium* its full size is obscured by the fact that it has not fully erupted). In Fig. 1 the orientation of this tooth has been altered, so that its crown can be seen in the same plane as those of the remainder of the series. This illustration shows that in both species there is a large hypoconulid flanked laterally by accessory cuspules. A long postero-internal buttress of the hypoconid runs between ento- and hypo-conulid in the specimen of *Oreopithecus* figured here (after Hürzeler). This might be an important difference from *Apidium*, were it not for the fact that this ridge is missing in some specimens of the former.

The lack of connecting links, interposed temporally and morphologically between these two primates, *Apidium* and *Oreopithecus*, renders claims of an ancestor–descendant relationship between them uncertain. However, the resemblance between the two is striking considering that they are separated in time by more than twenty-five million years. *Apidium* appears to be a primate having particular significance in determining the time of origin of the Oreopithecidae. Fragmentary as they are, when taken together, the Fayum primates indicate the possibility that cercopithecoids, pongids and oreopithecids were already distinct in the early Oligocene. Accurate conclusions about the bearing of both *Apidium* and *Oreopithecus* on the question of hominid origins will have to await the discovery of additional specimens and completion of studies now in progress.

MISCELLANY

"The Lunar Surface"

IN proposing new, or partly new, ideas in a field where many conflicting opinions are held, one is always open to misinterpretation and, unfortunately, the review of my book "Strange World of the Moon", appearing in *Nature* of March 12, p. 718, although fair in intention, misrepresents some of the points I make.

Thus, Dr. Pagel states that 'lunavoes' "are essentially broken bubbles of gas bursting out from a contracting surface". This is true only with a considerable degree of poetic licence. Neither Spurr nor I have proposed such an idea. We interpret lunar craters as calderas of collapse, produced by the caving-in of laccolithic domes due to the withdrawal of magmatic support. Escape of gases plays an important part in the process, but the uplift is not a 'bubble'. Collapse calderas are well known to geologists and a classical study of these structures was published by Howel Williams in 1941.

Dr. Pagel states that "Mr. Firsoff attributes ray systems to erosion by running water". This is a very unlikely explanation and he appears to have confused my interpretation of the rays as ejected matter accumulated in hollows with Spurr's suggestion that the radial gullies on the lower slopes of such formations as *Autolycus* and *Aristillus* may be drainage channels produced by torrential downpours during copious eruptions of steam.

Omitting minor inaccuracies, I pass to Dr. Pagel's unexceptionable conclusion that the presence of water "on the lunar surface is highly implausible", which is precisely what I said. Liquid water could exist on the surface of the Moon only exceptionally, temporarily and in small quantities. My contention is that, surface rocks being specifically lighter than water, it may exist beneath the surface. Such investigation as I have made also appears to show that there is no physical reason for denying the possibility of local surface deposits of ice and snow surviving for long periods in certain circumstances. Photodissociation is discussed.

V. A. FIRSOFF

MR. FIRSOFF's clarification of 'lunavoes' is very helpful, and I must apologize for having confused his explanation of rays with Spurr's explanation of radial gullies. My argument against the presence of water applies equally to ice and snow, which would be dissociated by solar ultra-violet radiation in the vapour phase.

B. E. J. PAGEL

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Tuesday, June 7

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.45 p.m.—Mr. G. J. Hurst: "Deserted Medieval Villages".* (Eighth of nine lectures on "Recent Archæological Discovery in Britain". Further lecture on June 14.)

Tuesday, June 7—Thursday, June 9

Institute of Personnel Management (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 9.30 a.m. daily—Conference on "The Implications of Recent Research for Personnel Management".

Wednesday, June 8

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. A. J. Dalton (National Cancer Institute, Bethesda, U.S.A.): "Electron Microscopic Studies on a Series of Plasma Cell Tumours in Mice".*

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7 p.m.—Annual General Meeting.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. J. B. Cragg: "Some South Atlantic Islands".

Thursday, June 9

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. G. E. Cook, Mr. D. G. King-Hele and Mr. D. M. C. Walker: "The Contraction of Satellite Orbits Under the Influence of Air Drag"; Mr. F. L. Curzon, Mr. A. Folkierski, Mr. R. Latham and Mr. J. A. Nation: "Experiments on the Growth Rate of Surface Instabilities in a Linear Pinched Discharge".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. S. J. Bach: "The Metabolic Fate of Protein-Nitrogen in the Mammal".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Professor, and a Lecturer in the Physics Department—The Secretary, Heriot-Watt College, Edinburgh (June 9).

Lecturer (with research experience in experimental nuclear physics) in Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (June 9).

Research Assistant in the Department of Botany, to assist in cytological studies in algae—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (June 9).

Assistant, Grade B (graduate, preferably possessing a special degree in geology, with ancillary botany and ecology), in the Natural Science Department, to teach geology and biological subjects—The Principal, Derby and District College of Technology, Kedleston Road, Derby (June 11).

Assistant Lecturer, Grade "B", in Biology, for work at G.C.E. ("O") and G.C.E. ("A") standard—The Clerk to the Governors, North Staffordshire Technical College, Stoke-on-Trent, Staffs (June 11).

Assistant Lecturer in the Department of Physiology—The Registrar, The University, Liverpool, quoting Ref. CV/N (June 11).

Assistant Lecturer or a Lecturer in the Department of Botany (with special reference to taxonomy); and a Research Demonstrator in the Department of Botany—The Registrar, University College, Singleton Park, Swansea (June 11).

Lecturer in Physiology—The Registrar, The University, Manchester 13 (June 11).

Lecturers in Physics; a Lecturer in Theoretical Physics; and an Assistant Lecturer in Physics—The Registrar, The University, Manchester 13 (June 11).

Research Assistant (graduate with a higher degree and special interests in instrumental astronomy) in Astronomy in the Department of Physics of the Faculty of Science—The Registrar, The University, Manchester (June 11).

Research Assistant (with a degree in genetics or in botany, biochemistry or microbiology with an interest in genetics) to Prof. D. Lewis, F.R.S., in the Department of Botany—The Secretary, University College, Gower Street, London, W.C.1 (June 11).

Principal Lecturer (with a degree and research experience in pharmacy, extensive experience in the teaching of all branches of pharmaceutics, and preferably industrial pharmaceutical experience) in Pharmacy—The Registrar, Bradford Institute of Technology, Bradford 7 (June 15).

Lecturer in Chemical Engineering—Prof. D. M. Newitt, F.R.S., Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, South Kensington, London, S.W.7 (June 18).

Lecturer (with a special interest in cartography) in Geography—The Secretary of University Court, The University, Glasgow (June 18).

Lecturers (2) in Physics—The Registrar, The University, Hull (June 18).

Temporary Lecturer in Pure Mathematics—The Registrar, University College, Singleton Park, Swansea (June 18).

Lecturer in Hydraulics and Hydrology in the Department of Civil Engineering—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (June 20).

Assistant in Research (with an appropriate honours degree) in Animal Physiology—The Secretary, School of Agriculture, The University, Downing Street, Cambridge (June 22).

Lecturer or Assistant Lecturer in Biology, Botany or Zoology, to take the subject to pass degree standard; a Lecturer in Chemistry; and a Lecturer in Mathematics—The Principal, Bede College, Durham (June 25).

Research Students in Physics, for work in the following topics: magnetic resonance of the solid state, gas discharge studies, investigations of defects in glass and other fibres, and studies on the properties of oxide cathodes—The Registrar, University College of North Staffordshire, Keele, Staffs (June 25).

Senior Research Assistant (with an honours degree, preferably in metallurgy or alternatively in chemistry, and some postgraduate or industrial research experience) in the Department of Metallurgy, to investigate a problem in the field of electrodeposition—The Registrar, The University, Nottingham (June 25).

Chair of Education in the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 27).

Thermal Syndicate Research Fellow in the Ceramics Division of the Houldsworth School of Applied Science, for research on the physics of silica glass—The Registrar, The University, Leeds 2 (June 28).

Lecturer in Plant Pathology (Virology) at Waite Agricultural Research Institute, University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 30).

Research Fellow in Chemistry, for work on the structures of physiologically active polypeptides—The Secretary, The University, Exeter (June 30).

Assistant Lecturer or Lecturer (preferably with research experience in genetics) in the Department of Biology as Applied to Medicine—The Secretary, Department of Biology as Applied to Medicine, Middlesex Hospital Medical School, London, W.1 (July 10).

Immunologist (medical graduate interested in tumour immunology) to develop a Section of Immunology in the Division of Pathology; an Electron-Microscopist (graduate in medicine with experience in pathology or an honours science graduate with histological experience) to be trained as electron-microscopist in the Division of Pathology; a Biochemist (honours graduate) for the Cyto-Chemistry Section of the Division of Pathology; and a Biochemist (honours graduate with research experience in lipid biochemistry) in the Division of Chemistry and Biochemistry—The Director of Research, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2 (July 15).

Lecturer (with a higher degree, preferably a doctorate of philosophy, with some research and teaching experience) in Chemistry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 15).

Senior Lecturer or Lecturer in Botany (Plant Physiology) at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 15).

Lecturer (with an honours degree in philosophy, and a special interest or qualification in either logic or the philosophy of science or the history of ideas) in Philosophy at the University of Canterbury, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 18).

Senior Lecturer in Physical Chemistry, and a Lecturer (with special interests in inorganic chemistry) in Chemistry at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, August 31).

Field Assistant (female, with an honours degree in geography, preferably with subsidiary geology and/or botany or zoology) at Malham Tarn Field Centre, near Settle, Yorks—The Secretary, Field Studies Council, 9 Devereux Court, Strand, London, W.C.2.

Grade B Assistant (graduate, preferably with industrial and/or research experience) in Physics—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

Lecturers (graduate metallurgists or physical chemists interested in extraction metallurgy, chemical metallurgy or metallurgical analysis) in Metallurgy—The Secretary, Sir John Cass College, Jewry Street, London, E.C.1.

Physical Chemist, Scientific Officer grade, to study the persistence and toxicity of residual films of insecticides—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Plastics Chemist or Plastics Technologist (preferably with appropriate research or industrial experience) in the Department of Materials, to assist in the organization and supervision of the teaching laboratories and to participate in the research activities of the plastics group—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Postdoctorate Fellow (with a Ph.D. degree (or equivalent) of a recognized university) in Biochemistry in the Psychiatric Research Unit situated in the University Hospital, Saskatoon, to carry out fundamental research into some of the biochemical aspects of mental illness—The Personnel Officer, Saskatchewan Department of Public Health, Health and Welfare Building, Regina, Saskatchewan, Canada.

Research Assistant (with a first degree of the University of London and an interest in ultrasonics and electronics) in Ultrasonic Physics—The Principal, Kingston Technical College, Fassett Road, Kingston-upon-Thames, Surrey.

Research Fellow (Senior or Junior) (with the degree of Ph.D., and preferably experience in research involving proteins) in the Department of Biological Chemistry, for work with Dr. J. L. Simkin on biosynthesis of proteins—Dr. J. L. Simkin, Marischal College, The University, Aberdeen.

Science Graduate (male or female) in the Laboratories of the Aberdeen and North-East Scotland Blood Transfusion Service

—The Regional Director, Aberdeen and North-East Scotland Blood Transfusion Service, Royal Infirmary, Aberdeen.

SCIENTIFIC OFFICER (honours graduate in chemistry or biochemistry) IN THE RADIOBIOCHEMISTRY DEPARTMENT, for biochemical research involving the use of radioactive isotopes, and in particular C^{14} and tritium—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks, quoting Ref. 60/3.

BRITISH DYESTUFFS AND WIDER CO-OPERATION IN EUROPE

THE European Free Trade Association Bill, which received Royal Assent on March 22, ended the system of protection which the British dyestuffs industry had enjoyed since the Dyestuffs (Import Regulation) Act was passed in December 1920 in accordance with an official pledge given by the Government in May 1918. That Act prohibited the import of dyestuffs except under licence granted by the Board of Trade on the recommendation of the Dyestuffs Advisory Licensing Committee, usually on the ground that there was no British equivalent or on grounds of price. Originally licences were granted when the price of the British product was more than three times that of the foreign equivalent, and during the years this factor was progressively reduced to 1·75; but by 1932 imports of dyestuffs were almost entirely of those not made in Britain.

The Dyestuffs (Import Regulation) Act was originally to run for ten years, but when in November 1930 the then President of the Board of Trade, Mr. W. Graham, announced the Government's decision to allow the Act to lapse, there were stormy debates in Parliament. In the Commons on December 4 the Government carried by a majority of 30 its motion to allow the Act to lapse, but a motion to continue the Act to December 31, 1931, was carried against the Government in the Lords. Afterwards, on December 17, the Government's majority fell to 6 on a motion to disagree with the Lords, and it was in this debate that the late Major A. G. Church, then general secretary of the Association of Scientific Workers, spoke and voted against his party, urging the importance of the industry to research and voicing the arguments raised by many leading scientists and industrialists in a discussion on the industry at the British Association meeting at Bristol in the previous September. The Lords insisted on their amendment, and on December 18 the President of the Board of Trade moved that the Commons should not insist on disagreement.

As a result, the Act was renewed annually under the Expiring Laws Continuance Act for the next three years, until in December 1933 a new Dyestuffs (Import Regulation) Bill was introduced by Dr. E. L. Burgin, then President of the Board of Trade. In the meantime the Import Duties Act, 1932, had been passed, under which, since March 1932, all imported dyestuffs had been subject to the general *ad valorem* duty of 10 per cent, and an Import Duties Advisory Committee established. When the Dyestuffs Industry Development Committee therefore reported in 1932 on the position and development of the industry in Great Britain, the questions whether further assistance to the industry was necessary and, if so, the form such assistance should take, were referred to the Import Duties Advisory Committee. This Committee in July 1933 recommended that the 1920 Act should be continued indefinitely, but that colouring matters not used in dyeing should be dealt with under the Import Duties Act of 1932. Intermediates, but not dyestuffs, should be subject to the general *ad valorem* duty of 10 per cent. Accordingly, the Bill introduced by Dr. Burgin proposed that dyestuffs not used in dyeing should be dealt with by the Import Duties Advisory Committee, and provided for the consideration of complaints by that Committee and for the imposition of duties up to 20 per cent on pigments. Most other materials from which the prohibition was removed by the Bill were already subject to duty under the Safeguarding of Industries Act or other Acts.

This Bill had a smooth and uneventful passage through both Houses of Parliament, although the Colour Users' Association maintained that the Act had already served its purpose and firmly established the industry; and the debates were marked by none of the heat or tension of those in December 1931. The Act, which received Royal Assent on March 28, 1934, continued in force until it was recently repealed under Clause 5 of the European Free Trade Association Act; but, as the Minister of State, Board of Trade, Mr. F. J. Erroll, explained in moving the second reading of the Bill on February 15 last, the Dyestuffs (Import Regulation) Acts had not been used since 1939. The obligation to eliminate qualitative restrictions on imports involved in participation in the European Free Trade Association necessitated the abandonment of the present system of prohibition of dyestuffs and their intermediates except by licence, and, in turn, this has entailed a decision to substitute protection by tariff.

The protective import prohibition is contrary to the general rules of the General Agreement on Tariffs and Trade, and dyestuffs obviously could not be excluded from the scope of the European Free Trade Association arrangements, although, as was explained by the Earl of Dundee in the House of Lords on March 8, Britain arranged in 1947 that we should be allowed, if licensing was terminated, to put on instead an import duty of 33⅓ per cent. Progressive liberalization of the import prohibition would involve the admission duty-free from member countries of the Association of increasing quantities of dyestuffs of types already produced in the United Kingdom. While it is difficult to predict the effect of this step, clearly, as Mr. Erroll observed, some difficulties for the British industry must be expected, and once imports have been allowed in duty-free from members of the Association, it would become extremely difficult to establish a tariff in the context of any wider free-trade area.

It was therefore important, said Mr. Erroll, to introduce as soon as possible a protective duty on dyestuffs and their intermediates imported from all foreign sources, and such a duty would be subject to progressive reductions on imports from member countries of the Association until, at the end of ten years, dyestuffs from such countries would be admitted free of duty. Mr. Erroll reiterated that repeal of the Dyestuffs Acts was one part of the Bill and a necessary step in the change-over from a system of protection by prohibition and licence to a system of protection by the tariff. In broad terms, the import of dyestuffs and their intermediates would receive the same treatment as other chemicals, and this section of industry would thus receive the same level and form of protection as was enjoyed by the rest of the chemical industry. Mr. Erroll assured the House that the dyestuffs industry had been duly consulted on the change-over, which would be effected by tariff orders, and said that amendment of the open general licence, operating from March 2, would be introduced to the House in due course.

It is perhaps the most emphatic testimony to the way in which over the past forty years the dyestuffs industry has been built up that this unique British system should have been terminated so quietly and almost without notice. The arguments as to the key importance of the industry advanced during the First World War and afterwards have not lost their importance, however, and it would ill become the British scientist or technologist to allow the system to end without saluting alike the vision and determination of those who first established it, who saw thirty years ago that it was maintained even at personal sacrifice, or the forebearance and co-operation between makers and users which made the system work. Both dyestuffs manufacturers and users of dyestuffs in the textile industry appear to expect very little change in the pattern of trade under the new conditions, and the dyestuffs industry seems to be reasonably confident of continuing to supply 90 per cent of the requirements of the textile industry in Britain. Moreover, the co-operation of the users in building up the British industry, especially thirty years or more ago, has established a strong community of interest as well as a tradition of co-operation. Dyers have come to depend largely on, the technical services of the dyestuffs manufacturers as well as on his supplies of colour, and those servicet are unlikely to be so readily available from overseas sources. While it is too early to be sure of the effect of the new arrangements on the industry, there appears to be every reason for confidence that the British industry will continue to flourish and to make important contributions in products and technique.

The dyestuffs industry is not the only reason why the European Free Trade Association Act has at least passing interest for the scientist. Like other measures towards freeing European trade, it should serve to develop that community of interest and freedom of communication which science and technology alike require for unimpeded advance, and which are the greatest safeguard against waste of effort or resources. Two recent broadsheets issued by Political and Economic Planning bring this out a little further. The earlier one, "European Unity—A Review" (No. 436; September 28, 1959), assesses generally such institutions as the Economic Commission for Europe, the Organization for European Economic Co-operation, the Council of Europe and the North Atlantic Treaty Organization, and the obstacles to the rationalization of such organizations. A much more elaborate analysis has also been published by Political and Economic Planning under the title "European Organizations"*, as the outcome of the work of a research group.

Apart, however, from the summary and conclusions of this report, and the long chapter on the Organization for European Economic Co-operation, the broadsheet is likely to meet most of the needs of the scientist or technologist, particularly if supplemented with the second broadsheet, "Challenge and Change" (No. 440; March 14, 1960). This broadsheet contains four papers delivered last autumn at a conference, "Is the Economy of the Western World splitting apart ?", arranged by the Committee for Economic Development, an American research organization conducted on somewhat similar lines to Political and Economic Planning. In the first of these papers, Sir Oliver Franks, dealing with "The New International Balance: Challenge to the Western World", refers to the importance of a right answer to our relation to the developing countries and a proper allocation of our resources to this cause. The same point is made by Mr. P. van Zeeland in his paper, "The Economic Community: Move towards Atlantic Union", in discussing the relations between the Common Market and Africa. Mr. van Zeeland suggested in particular the creation of an Atlantic economic community, open to all free peoples, averse to discrimination and ready to serve the under-privileged, while Mr. P. C. Hoffman, in his paper, "Development and Growth: Goals for a Crucial Decade", dealt at some length with assistance, including technical assistance, to the under-developed countries. The significant emphasis placed on these problems of the relations between the relatively advanced and the under-developed countries should not be lost on the scientist and technologist, who have much to contribute in that field. There is undoubtedly much still to be done to work out the most effective means by which such assistance can be given, before we can regard the channels of communication, even of information, reasonably clear, and the waste of scientific and technical resources or man-power unlikely.

HEISENBERG, PHYSICS AND PHILOSOPHY

Physics and Philosophy

The Revolution in Modern Science. By Prof. Werner Heisenberg. (World Perspectives.) Pp. 176. (London: George Allen and Unwin, Ltd., 1959.) 15s. net.

FROM the group of physicists who, thirty-five years ago, built the rational foundation of the quantum theory of atomic systems, the figure of Heisenberg emerges as the leading one, both by his creative imagination and by his powerful grasp of the novel logical relationships which confront us in this domain. To those who, like myself, look to him for continued guidance and inspiration, a book containing his views on the philosophical aspects of modern physics would raise high expectations. It is therefore with great dismay that I am forced to confess my disappointment, and to set down, for the edification of potential readers, my reasons for it. Just because I regard Heisenberg as one of the highest authorities in the domain of fundamental physics, I shall do this with unsparing frankness.

The book reproduces the text of a course of Gifford Lectures; I was unable, however, to discover any plan or leitmotive in this course; the single chapters might just as well have been detached lectures on their respective subjects, and they are not even presented in any obvious logical order. The lack of any pre-occupation with systematic or scholarly discussion is also apparent from the complete absence of references to any books or articles which would allow the reader to pursue the subject of his choice. Indeed, the author, who is undoubtedly well read in some parts at least of philosophy and history, has taken so little care in checking his facts that his sketches of the historical development of philosophical and scientific problems are everywhere marred by serious inaccuracies, which are the more disturbing as the inexpert reader does not get any hint about the sources of the author's information. Lest one suspect me of being pedantic, let me just mention that even such widely known historical developments as that of electromagnetism or the notion of the atom in chemistry are presented in a false light. It is unfortunately no exaggeration to say that as an exposition of the basic data which the author takes as a starting point for his comments and considerations, the book is worse than valueless: it is positively misleading.

One may perhaps console oneself by observing that, after all, one is not looking here for any systematic study, but rather for some conversation, as it were, with the author about the thoughts and reflexions which are familiar to him and which inspire him in his creative work. From this point of view the book has undeniably documentary value: but how much more interesting would have been the conversation if the author had been more attentive to his interlocutors! In the chapters more specially devoted to the physical problems in which he is no longer a negligent dilettante, but a supreme master, the author has apparently made no effort to express his thought with the precision and neatness one has a right to demand from him: he alternates uneasily between a popular exposition of results (which is not his *forte*) and a hazy, superficial discussion of the logical and philosophical issues, which certainly does not convey to the layman an adequate idea of their importance.

Turning now, with these reservations in mind, to the contents of the book, one again meets with disappointing features. One of the lectures is devoted to Greek philosophy, another to the modern philosophical systems from Descartes to Kant; these surveys, however, are presented as mere catalogues of ideas which appear to follow each other in arbitrary succession; and this unhistorical approach is still more underlined by the fact that the whole discussion of these philosophical conceptions is directed towards their assessment in comparison with our present views, derived from the development of atomic physics! It would be hard indeed to find a less-inspiring subject than the consideration of the epistemological situation of quantum theory from the point of view of the Kantian *a priori*.

With regard to the epistemological problems just mentioned, Heisenberg's exposition naturally follows the line of argument which he has himself so decisively contributed to establish, and which he calls, in homage to Niels Bohr's great leadership, the "Copenhagen interpretation". He even devotes a whole chapter to the thankless task of tearing to pieces the various objections raised against this conception, and this is the best chapter of the book. But the account he gives of the "Copenhagen" ideas is unfortunately not so good as it ought to be; and certainly not one of the physicists now working in Copenhagen would subscribe to the general philosophical attitude underlying this account. Altogether, it would be better to discard such an ambiguous expression as "Copenhagen interpretation", were it only because it falsely suggests that there could be other possible interpretations of quantum theory.

I am particularly unhappy about the chapter entitled "Language and Reality in Modern Physics", in which it is suggested that in the description of atomic events the classical concepts are used "in a somewhat vague manner", reminding us "of a similar use of language in daily life or in poetry". Taken literally, such a statement runs counter to the very spirit and purpose of the unceasing efforts of the Copenhagen physicists to develop an epistemology guaranteeing a fully precise use of the classical concepts, exempt from contradiction in every conceivable situation. Of course, the wave-concept, when applied to an electron, has not the same relation to possibilities of observation as when it is applied to a beam of light; it is tempting to say, for example, that the wave-pattern of electrons in a crystalline lattice, constructed by the crystallographers from X-ray diffraction measurements, represents a 'blurred' or 'smeared-out' picture of reality: but this temptation should be resisted, not encouraged. For the term 'blurred' or 'smeared-out' implies a reference to the particle picture, which, according to the rules of interpretation, cannot legitimately be used in this case. I fail to understand why the author, instead of insisting upon this kind of language problems—well known to physicists, but puzzling to outsiders—has preferred to dwell at length on questions of multi-valued logics, which can only confuse everybody.

If this book had been better, I should have deplored its inclusion in a collection which, under the grandiloquent title "World Perspectives", assembles all the shades of woolly thinking with which our time is afflicted. In this series, Heisenberg's text appears preceded by an introduction which a professional philosopher has thought fit to write for it. But I am loath to load further reproach for a missed opportunity on a colleague whom I deeply revere; to see his book saddled with that introduction must be the punishment meted out to him by the gods.

L. ROSENFELD

ZOOLOGICAL LITERATURE

The Zoological Record

Vol. 93. Being the Records of Zoological Literature relating chiefly to the year 1956. Edited by G. Burder Stratton. Pp. v+2,014. (London: The Zoological Society of London, 1959.) 160*s*.

THE "Zoological Record" is yet another of the many publications held up by the printing dispute last year, and great credit reflects upon the editor and recorders for its appearance after such a comparatively short delay. The present volume is 162 pages longer than the previous one (then the largest on record), and although part of this increase (69 pages) is the result of including the Trilobita for 1955 as well as 1956, there is once again evidence of the rapid expansion of the subject in recent years. The relative size of the various sections shows comparatively little change, Insecta still remaining by far the largest with 536 pages, rather more than a quarter of the volume. This section is prepared by, and obtainable from, the Commonwealth Institute of Entomology; and is arranged with a list of all the titles coming first, with full references following the author's name, and each reference is given a serial number; this year rising to 3,444. Then follows the subject index prepared for those working on general problems, without affecting its importance for taxonomists. This is divided under eight headings: general, morphology, development, physiology, bionomics, ecology, evolution, and geographical or faunistic, and information is arranged by orders under each heading. Finally, there is the systematic index where orders and families are arranged in alphabetical sequence. An appeal is made to writers of systematic papers to mark new synonyms with the words (*n. syn*) as otherwise it is impossible to ensure that they will be correctly recorded. A similar plan is followed in the other seventeen sections with the exception that the use of serial numbers has now been abandoned. These sections, compiled by twenty-four recorders, experts in the various branches of the subject, remain the same as in previous volumes, with the exception that the classes Amphibia and Reptilia are now separated instead of being united in one section.

Protozoa; Vermes—a very heterogeneous assembly; Mollusca; Arachnida; and the various classes of vertebrates comprise most references. Apart from the first two, these sections include animals which attract the attention of amateurs and this may explain their size. It is difficult to understand, however, why such very large groups as Coelenterata and Echinoderma do not receive more attention, but economic importance is doubtless significant. A total of 2,042 generic and subgeneric names is listed in the final section, made up as follows:

Protozoa 78; Porifera 9; Coelenterata 51; Echinoderma 8; Vermes 82; Brachiopoda 96; Bryozoa 10; Mollusca 153; Crustacea 84; Trilobita (1955) 85, (1956) 62; Arachnida 200; Insecta 974; Protochordata 4; Pisces 69; Amphibia 6; Reptilia 16; Aves 5; Mammalia 50.

The "Zoological Record" is compiled for the Zoological Society of London and published by it. The very heavy expenses involved are met, in part, by donations from institutions and individuals amounting, during 1956, to a total of just over two thousand pounds. All these donations come either from the British Commonwealth or the United States, with the exception of the International Council of Scientific Unions (£500) and the Naples Zoological Station (£10). It is regrettable that a publication of this nature, the only one which attempts to give each year a complete list of zoological publications through the world, and indispensable to any zoologist trying to trace the literature of his subject, should not receive support from zoological institutions in other countries.

EDWARD HINDLE

GENETIC RECOMBINATION

Exchange of Genetic Material

Mechanisms and Consequences (Cold Spring Harbor Symposia on Quantitative Biology, Volume 23.) Pp. xvi+433+2 plates. (Cold Spring Harbor, L.I., New York: Long Island Biological Association, 1958.) 8 dollars.

THE recombination of genetic materials, its mechanism, control and significance, constitutes one of the great central problems of genetics. Recombination was first observed by Mendel, but the free recombination of genes carried on different chromosomes, such as he was presumably seeing, present little problem of mechanism. However, with the discovery of linkage groups and the analysis of the restricted recombination between the genes of a group came the much more difficult, and theoretically much more significant, question of how homologous chromosomes exchange material during the process of meiosis. This commanded wide study by genetical, and later cytological, means for some thirty years and much was discovered about the process: interference, the non-random distribution of recombination along the physical chromosome and the reciprocity of exchange were all established, but perhaps not surprisingly the mechanism eluded us. There were theories but no finality; and here the study of how recombination comes about rested for more than a decade. Interest revived with the advent of micro-organisms as subjects of genetical investigation, for these not only offered the technical advantages of analysing recombination too rare to be followed even in *Drosophila* but also revealed new mechanisms by which it could come about—parasexuality, transformation, transduction and the like—and also brought to light the phenomenon of gene conversion with its curious and as yet unclear relation to recombination. An additional fillip was given by the growing understanding of how deoxyribonucleic acid is organized.

This new interest in the mechanism of recombination is well exemplified by the Cold Spring Harbor Symposium of 1958. Sixteen of the papers deal with recombination as seen in various bacteria and fungi, and these include the address with which Sir Macfarlane Burnet opened the symposium. Two further papers specifically consider it in relation to the replication and arrangement of deoxyribonucleic acid in the chromosomes. Non-reciprocal recombination and conversion, transduction and the possible restriction of effective pairing to specific sites are all considered. The unity and the duality of mechanisms underlying recombination in its various manifestations are both argued. Five papers, all but one of them dealing with *Drosophila*, present cross-over studies of the more classical type. There is as much information and as much stimulation in these twenty or so papers as there is absence of agreement on conclusions and points of view. This is no doubt as it should be in a field of active study, but it warns us that understanding of how recombination comes about is as elusive as ever.

The symposium was not confined to mechanisms but considered consequences as well. It has long been realized that the significance of sexual reproduction lies in the recombination it makes possible. Not until the development of polygenic theory, however, did the full importance emerge of recombination as the prime agent of genetic flexibility in populations. This relation of variation and selective response to recombination is explored further in three papers, and several others discuss the control of recombination by both its direct restriction and its reduction to ineffectivity through inbreeding and apomixis in the wild. Again, as with mechanisms, we see a diversity of approach, but this time with more unity of conclusion; polygenic recombination is the key to understanding variation, adaptation and change in the wild.

The breadth of the symposium is finally emphasized by the inclusion of a number of papers dealing with such varied topics as recombination in relation to the stability of genes, nuclear-cytoplasmic relations and the remarkable phenomenon of paramutation in maize. If evidence were needed that recombination is of central significance in genetics this symposium most certainly supplies it. It is scarcely to be recommended as reading for the novice, but few geneticists will fail to gain stimulation and profit from it no matter where their interests lie between the chemical basis of heredity and the behaviour of populations in the wild. KENNETH MATHER

THE PLEISTOCENE ERA

The Pleistocene Period

Its Climate, Chronology and Faunal Successions. By Prof. Frederick E. Zeuner. Pp. 477. (London: Hutchinson and Co. (Publishers), Ltd., 1959.) 42*s*. net.

BEFORE the Second World War, most of the books about the Pleistocene Period were becoming out of date, and the publication of Prof. Zeuner's book "The Pleistocene Period" by the Ray Society in 1945 was therefore most welcome. The subject of the present review is an enlarged edition of that work, brought up to date by the addition of a chapter which presents "New Evidence", the main body of the work remaining almost unaltered. This arrangement is unfortunate, as it fails to include references to many new publications which have appeared since 1945.

The book starts by describing the evidence of past climatic changes as deduced from glacial and periglacial beds and from physiographical features, and to a lesser extent from the study of fossil plants and animals. On this rather one-sided basis the sequence of climatic fluctuations for most parts of the Earth are examined in detail. This is followed by Prof. Zeuner's well-known comparison between the climatic results thus assembled and the calculations by Milankovitch of the variation of the amount of heat received by the Earth from the Sun during the past 600,000 years or so. He has always believed that these two lines of evidence agree remarkably well, although some geologists have never accepted this point of view. Whatever one's personal opinion may be, an important statement by Prof. Zeuner (on p. 372) points out that a radioactive test by the potassium-argon method has recently confirmed the dating of the end of the Elster glacial phase in Germany as the same as that calculated from the astronomical theory. He also believes that these climatic fluctuations caused changes in sea-level, and this leads him to a correlation of the Pleistocene beaches, mainly according to their heights. It is unfortunate that the author seems to ignore much work by Lecointre and others on the correlation of the marine beds by faunal methods, as some of that work agrees well with Zeuner's conclusions based on the heights of the shore-lines. Finally, the chapter on the rate of evolution of some land-mammals is reprinted in its original form in this new work.

The main subjects included in the new additional chapter are based mainly on Prof. Zeuner's own observations, and include some features of the terraces of the Thames and of part of the Rhine basin; of the Nile Delta and of some Pleistocene beaches of the Canary Islands, Norfolk and Devonshire. In Appendix 3 (pp. 378–379) an interesting table sums up the shore-line heights from a large number of places, but one wonders whether there is any advantage in the sequence being represented upside-down, with the youngest events at the bottoms of the pages?

It is unfortunate to have to record omissions from this stimulating book, but they are mentioned here in the hope that they can be put right in future editions. As an example, no mention is made of the investigation, mainly by pollen analysis, of interglacial plant beds in Holland and Germany and places like Hoxne in England, although this work would have given so much information about climatic fluctuations. Again, some methods of investigating glacial tills, especially that of stone orientation, seem to be ignored, although they are so useful for correlation.

But with all its defects, this book, with its unique bibliography, is a valuable work of reference for anyone who is trying to solve the puzzles of the Pleistocene Period. D. F. W. BADEN-POWELL

METHODOLOGY AND SUPERCONDUCTIVITY

A New Method in the Theory of Superconductivity

By N. N. Bogoliubov, V. V. Tolmachev and D. V. Shirkov. Translated from the Russian. Pp. iii+121. (New York: Consultants Bureau, Inc.; London: Chapman and Hall, Ltd., 1959.) 5.75 dollars; 50*s*.

THIS monograph is addressed primarily to theoretical physicists: from the start the formalism of quantized fields is employed. The presentation is fairly clear, and the calculations are easy to follow.

The 'new method' of the title consists in the application of a certain transformation of the field variables. The Hamiltonian of the system of interacting electrons is re-expressed in terms of a set of 'quasi-particles'. The transformation is applied to the Bloch-Fröhlich model of a metal and to more complicated models, with Coulomb interactions and with renormalization of the phonon energy and the electron-phonon coupling constant.

The calculation of energy-levels seems convincing, and certainly suffices to explain some of the properties of superconductors. The energy spectrum has a gap, and it has been known for some time that many of the properties of superconductors can be derived from a phenomenological energy-gap model—for example the specific heat or the microwave absorption edge. The electrodynamical properties are another matter, and their treatment is less than adequate. The authors make it fairly plausible that the electrical resistance should vanish, but they do not discuss the Meissner-Ochsenfeld effect. It is just here that certain difficulties arise, which have been the source of much controversy.

The transformation has some strange features. The procedure introduces singularities, and then selects the parameters of the transformation to remove them again, to the same order of perturbation theory. Moreover, although the starting point of the theory is a model with a fixed number of electrons, after transformation the total number of electrons is no longer a good quantum number. The use of a chemical potential for the electrons enables calculations to proceed, but the physical meaning of the slight blurring of the electron number is obscure. The states of the system are identical with those found by Bardeen, Cooper and Schrieffer, and indeed the lack of sharpness of the electron number is also a feature of their theory. The new method is, however, both more elegant and more widely applicable ; the form of the theory due to Bardeen, Cooper and Schrieffer could not be applied directly to the Bloch-Fröhlich model.

The claim is made that this volume constitutes a complete solution to the problem of superconductivity. For reasons set out above, I do not accept this claim, but nevertheless warmly welcome the appearance of the volume. Bogoliubov's quasi-particle transformation is a very valuable addition to the methodology of theoretical physics, even if it is not quite an all-purpose tool. It is extremely useful to have a connected and systematic account of the method and its application to superconductivity.

C. G. Kuper

HOROLOGY IN MEDIEVAL CHINA

Heavenly Clockwork

The Great Astronomical Clocks of Medieval China. By Dr. Joseph Needham, Dr. Wang Ling and Dr. Derek J. de Solla Price. Pp. xv+254+21 plates. (Cambridge : At the University Press, 1960. Published in association with the Antiquarian Horological Society.) 65*s.* net.

Dr. NEEDHAM'S researches into the history of science and technology in China are well known for the breadth of their scope and the vast array of new material which he has brought to light, and the book under review throws a spotlight of great brightness on one aspect of this history. With the help of his distinguished collaborators Dr. Needham has revealed the existence of a school of Chinese makers of astronomical clocks and armillary spheres at work over the period A.D. 100–1600, and in this book, besides describing these in great detail, has shown their relationship with the early water-clocks which preceded them and the wholly mechanical clocks of Europe which appear to have developed independently of the Chinese technology from the late thirteenth or early fourteenth century onwards.

The first five chapters of the book consist of an elucidation and explanation of a Chinese text "New Design for a Mechanized Armillary Sphere and Celestial Globe" written by Su Sung in A.D. 1090, the appropriate sections of which are fully translated.

Su Sung's 'Clock' was a great astronomical clock-tower more than 30 feet high, surmounted by a huge bronze power-driven armillary sphere and containing an automatically rotated celestial globe ; while on the outside of the tower various automata appeared through doors to ring bells and gongs indicating the time.

Perhaps the most remarkable feature of the whole structure was, however, the water-wheel escapement inside the tower, which controlled the time-keeping and forms a 'missing link' between water-clocks of uniform flow as employed in the Egyptian, Greek and Roman civilizations and the all-mechanical intermittent escapements of medieval Europe.

The water-wheel carried a succession of troughs into which water flowed uniformly, and when a trough became full a weighbridge tipped and allowed the wheel to turn until it was brought to rest by a form of detent with the next trough beginning to fill. This operation was repeated every quarter of an hour. The book reproduces original illustrations of the tower and of many of its details and includes carefully drawn modern diagrams clearly illustrating the detailed operation of the water escapement and the other important mechanical features of the clock.

In interpreting these, the authors were set the task of recognizing unfamiliar Chinese technical terms for the various parts : this they eventually succeeded in doing without ambiguity, and the vocabulary they thus learned was invaluable to them in interpreting earlier Chinese texts on similar subjects.

These earlier texts, in fact, reveal that Su Sung's clock was not the pioneer, but the culmination of a series of astronomical clocks, and the sixth chapter of the book traces these backwards to their origin in the second century A.D. at the hands of Chang Heng (A.D. 78–*c.* 142), well known as the inventor of the seismograph of A.D. 132.

Chang Heng's clock consisted of an armillary sphere rotated by the force of flowing water, and after a careful examination of all the evidence the authors conclude that this implies drive by a water-wheel with scoops. The first water-clock with an escapement of the Su Sung type they attribute to the third decade of the eighth century.

The authors now turn their attention to Chinese clockwork after Su Sung and find a steady progression without spectacular developments, the function of the mechanism being still to rotate an armillary sphere and operate automata rather than to indicate the hour. The next turning point is the arrival of the Jesuits in 1583, bringing contact with the European clock-making tradition.

It appears, somewhat surprisingly, that the mechanical striking clocks which the Jesuits took with them to China created a great impression there and added much to the prestige of their bearers ; later, during the seventeenth and eighteenth centuries, a considerable export trade in clocks from Europe to China developed

The main part of "Heavenly Clockwork" concludes with a review of the early development of European mechanical clocks, the conclusion being that recently put forward by Dr. Price that the mechanical clock was a by-product of an elaborate mechanical mechanism for driving globes and orreries rather than an independent invention as a pure time-keeper.

The above rapid survey does scant justice to the immense scholarship and detailed labour which went into the creation of "Heavenly Clockwork" and is set down therein in a most orderly fashion. The book is both immensely learned and very readable.

It has been published in association with the Antiquarian Horological Society, before which Dr. Needham first set forth his discovery of the Su Sung text in a lecture on January 11, 1956.

F. A. B. Ward

Steric Course of Microbiological Reactions

Edited by G. E. W. Wolstenholme and Cecilia M. O'Connor. (Ciba Foundation Study Group, No. 2.) Pp. viii+115. (London: J. and A. Churchill, Ltd., 1959.) 12s. 6d. net.

THE volumes describing the proceedings of the three-day and four-day conferences arranged by the Ciba Foundation are well known, and they have firmly established themselves as an important guide to current research in the sciences allied to medicine. This little book represents a new venture, namely, publication of the proceedings of a one-day study group. It contains five communications, preceded by an introduction by the chairman (A. Neuberger). The first (by F. H. Westheimer) is a historical review of the steric course of microbiological reactions. This is followed by articles on the mechanism of hydrogen transfer with pyridine nucleotides (K. Wallenfels), steric mechanisms in reactions of lactic acid (N. O. Kaplan), and the steric and molecular specificity of steroid dehydrogenases (P. Talalay and H. R. Levy). The final communication, on the steric course of some microbiological and enzymic reductions of ketones, is by Prof. V Prelog of Zurich, in whose honour this particular study group was organized.

These papers describe different aspects of an exciting and rapidly advancing branch of enzyme research, one which is of importance to biochemists and organic chemists alike. They are presented with great clarity, in spite of the complexity of the subject. They could be read and enjoyed by final-year honours students as well as by postgraduate workers, and for this reason the low price of the book is especially welcome. The papers are well illustrated with chemical structures, curves of reaction rates, diagrams of suggested means of attachment of enzymes to their coenzymes and substrates, and so on, and they are accompanied by a detailed account of the discussions which followed. According to the preface, the publishing of the first four of these one-day study group conferences is regarded as an experiment. Judging by this sample, the experiment must be considered highly successful. It is greatly to be hoped that these stimulating accounts of the work of the study groups will continue to appear from time to time, together with the volumes of the longer conferences.

D. C. HARRISON

Milk Testing

The Laboratory Control of Milk. By Dr. J. G. Davis. Second edition. Pp. xiv+309. (London: Dairy Industries, Ltd., 1959.) 30s.

THIS book is intended to provide all the necessary information for the routine control of milk by those concerned with laboratory work in collecting depots and processing dairies. It is therefore in the nature of a selection of standard methods for the sampling and chemical and bacteriological examination of milk for use in the dairy industry. The author has collected a great deal of information into a small publication. The sections dealing with the sampling of dairy products and the organization of the dairy laboratory are very good, but the author is at his best when dealing with the bacteriological tests. The section dealing with chemical tests might be criticized because it consists to a very large extent of reprints of British Standards specifications, which are readily available from other sources. The section dealing with the calibration of glassware—a basic need in any dairy laboratory—is dealt with very scantily and is not given sufficient attention.

The publication would be a valuable addition to the library of any dairy laboratory, and provides an easy means of reference to some of the more rarely used techniques which may be required for special investigations. However, the author does not deal fully with these methods, but all too often only provides references which will be difficult to obtain in the type of laboratory where the book will be of greatest use. The book is well printed, on the whole well written, and very free of mistakes. The most serious error is on p. 86, where it is stated that the total nitrogen is automatically determined when the casein is estimated.

A. L. PROVAN

A Supplement to "Helium"

By E. M. Lifshits and E L. Andronikashvili. Translated from the Russian. Pp. v+167. (New York: Consultants Bureau, Inc.; London: Chapman and Hall, Ltd., 1959.) 7.50 dollars; 60s.

ONE gets the curious impression, on reading this book, that one has been here before, and then one realizes that although the book has only now appeared in English translation, it was actually written in 1949. In other words, it was written, from its notions about liquid helium, in pre-Feynman days, and from its style and ethos, in the days of Stalin.

The great virtue of Keesom's "Helium" is that it contains every measurement made and every idea expressed on helium, good, bad, and indifferent, from the year one up to near the year 1942, when the book was published. All the ideas were allowed to find their own level with only the gentlest help from the author. Thus the book has an abiding value in spite of its appearance before the Landau theoretical break-through in the mid-'forties and the Feynman theoretical break-through in the mid-'fifties.

The "Supplement to Helium" is entirely different in character. It is a Russian view of the work done on liquid helium during the late 1930's and the 1940's when the Russian contribution was undeniably outstanding, but it was written at a time when it was apparently politically necessary to make it appear that non-Russian efforts were at best confused and at worst wrong-headed. The present reviewer gets off rather lightly in having his work described as "carried out under very complicated conditions . . . ", but Tisza, whose contributions to the theory of helium-II have been of very great importance, is treated very unfairly indeed. A decade ago one could sympathize with Russian colleagues who were in a difficult position, but it would have been an act of grace on the part of the authors if they had modified the text prior to its present translation. As it is, the repeated slanging somewhat mars an otherwise quite useful addition to the literature on liquid helium.

From the point of view of readability, appearance and accuracy the book is no great advertisement for either the Consultants Bureau or for the "multilith process from the International Business Machines, Ltd., 'cold' type". The printing is uneven and there are many blemishes, the mathematical type-setting is poor, the references in the text to figures and equations are sometimes wrong, and there are other proof errors such as Michels's name appearing as Milelson on p. 100.

J. F. ALLEN

THE VISUAL SYSTEM OF *OCTOPUS*

(I) Regularities in the Retina and Optic Lobes of *Octopus* in Relation to Form Discrimination

By Prof. J. Z. YOUNG, F.R.S.
Department of Anatomy, University College, London

THE capacity of an octopus to learn to make distinct reactions to differing visible shapes depends largely upon analysis of the vertical and horizontal extents of the figures[1]. Certain regularities now found in the retina and optic lobes provide clues to the mechanism for computing in these two directions.

The cells of the optic lobes show a bewildering variety of shapes. Often it is not possible to distinguish clearly between dendrites and axons, or to establish histologically the probable sites of origin of action potentials or the direction of conduction of the cells. Some of the cells have orientated dendritic trees within which there may be complex interactions such as are known in neurons of somewhat similar form in Crustacea[2,3]. There are sufficient data to suggest that the shapes and anatomical arrangements of the cells are of fundamental importance in the coding system. Deutsch[4] has proposed a hypothesis based on the general arrangement of the system as revealed by previous workers[5,6]. Further study now provides additional evidence of regularities It must be emphasized, however, that the forms of the cells are so complicated and difficult to investigate that much further work will be needed before it is certain which features are significant.

The outer segments of the retinal elements, directed towards the centre of the eye, form squares ('rhabdomes') as seen in tangential section, separated from each other by pigment granules[7] (Fig. 1). Further examination shows that the rhabdomes are orientated in the dorso-ventral and horizontal planes of the eye, as it is usually held with the pupil horizontal.

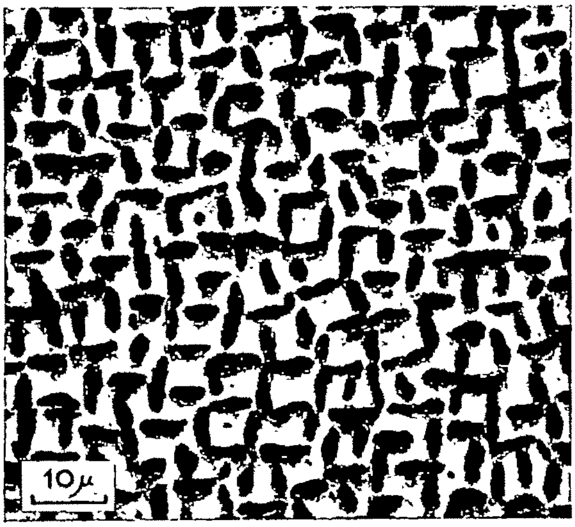

Fig. 1. Photograph of tangential section of retina of *Octopus*. Only the pigment shows, the rhabdomes being unstained. The long axis of the figure is dorso-ventral

Each rhabdome contains four 'rhabdomeres', composed of piles of tubules[8,9], and these lie with their long axes approximately in the vertical plane in one pair and the horizontal plane in the other pair in each rhabdome. The rhabdomes are connected to inner segments, each with a nucleus and nerve fibre, and counts show that there are twice as many nuclei as there are squares in the retina. Each rhabdome thus contains two receptor units (retinal cells), probably arranged as in Fig. 2. There are altogether 1–2 × 10^7 nuclei—a density of about 50,000 per mm.[3]. There are no striking differences in density in the central and peripheral parts of the retina.

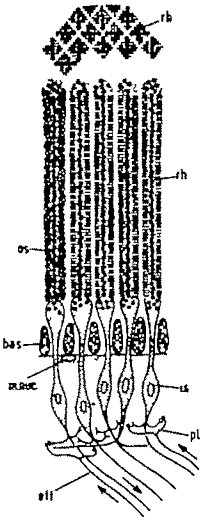

Fig. 2. Diagram of probable arrangement of the elements of the retina; above as seen in a tangential section, below in radial section. *bas.*, basal cell (which probably sends branches between the rhabdomes), *eff.*, efferent axon to the retina; *i.s*, inner segment; *o.s.*, outer segment; *pl.*, plexus beneath retina; *rh.*, rhabdomes. It is calculated that each retinal unit (pair of rhabdomeres) subtends a visual angle of 1 3′

The processes of the retinal receptors pass through a plexus and then through a chiasma that inverts the display in the dorso-ventral plane. They end within the optic lobes mainly in a complicated plexiform layer, the deep retina. This layer shows the following features in Cajal and Golgi preparations:

(1) A marked layering; four layers of tangential fibres are recognized, separated by four in which they are mainly radial (Fig. 3).

(2) Each optic nerve fibre has endings at more than one depth in the plexiform zone. The endings are mainly either superficial or deep, but there are also intermediates.

(3) Numerous amacrine cells send processes that spread to increasing distances with increasing depth (Figs. 3 and 5). These cells often do not show one distinct process that could be called an axon, though

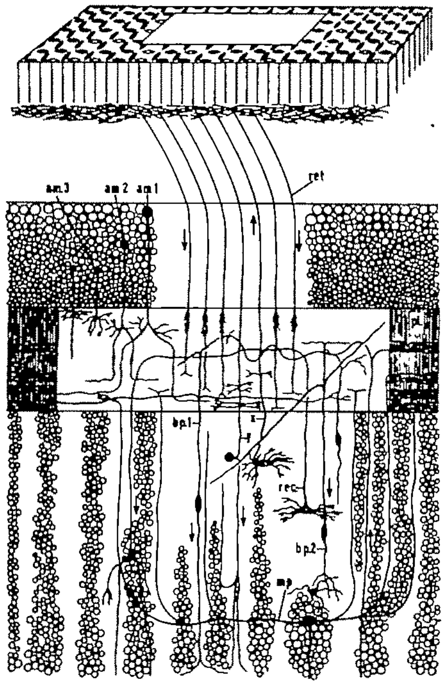

Fig 3. Diagram of the structure of the outer part of the optic lobe of *Octopus*. The retina is shown above with the image of a small rectangle. *am*. 1, 2 and 3, amacrine cells; *bp*. 1 and 2, bipolar cells the dendrites of which at different levels in the plexiform zone are orientated in opposite directions; *mp*., multipolar cell with many dendrites reaching to plexiform layer; *pl*., plexiform layer; *rec*., cell with dendrites in plexiform layer and a recurrent axon, *ret*., retinal nerve fibre. *x* and *y* cells with efferent processes to the retina, *x* has short basal processes, *y* long ones. All the cells are shown very schematically. A rectangle of 20 cm.^{2} seen at 1 m. would produce an image covering 14,000 retinal cells. A length of 100μ on the surface of the lobe corresponds to a visual angle of 40′, receiving some 30 optic nerve fibres

it is possible that these are unseen with the light microscope. If these cells ensure that excitation occurs where their processes overlap they may produce activity in the more superficial layers for points near together on the retina and in deeper layers for those more distant, thus serving to produce a neural representation of length. However, without information as to the physiological characteristics of such cells, it is not possible to say exactly how they function. An alternative possibility is that they serve to produce inhibition when neighbouring retinal elements are active, sharpening the effect of contours.

(4) Deep to the plexiform layer are further layers of small cells. Some of these are amacrines. Others have numerous processes in the plexiform layers and an axon that passes outwards into an optic nerve Fig. 3) and presumably provides an efferent pathway to the retina. Collaterals have been described at the base of the inner retinal segments[5,6], and there are thus probably synaptic connexions in the plexus behind the retina, as in *Limulus*[10]. The efferent cells to the retina also have basal processes, sometimes long (Fig. 3).

Table 1. NUMBER AND LENGTHS OF FIBRES IN AN AREA OF 22,500μ^2 IN THE PLEXIFORM LAYERS OF THE OPTIC LOBE OF AN OCTOPUS (CAJAL'S METHOD)

Layer of plexus	Degrees from horizontal 75–105	105–135	45–75	135–165	15–45	165–180 0–15
Second tangential						
Number	39	8	13	6	5	13
Length (μ)	1,455	393	462	204	179	531
Mean length (μ)	37	49	36	34	35	50
Third tangential						
Number	24	18	11	16	11	19
Length (μ)	625	447	373	490	445	664
Mean length (μ)	26	25	34	31	41	35
Fourth tangential						
Number	26	14	14	11	13	16
Length (μ)	760	450	321	357	359	415
Mean length (μ)	29	32	23	32	29	26
Total						
Number	89	40	38	33	29	48
Mean length	32	32	30	32	34	34

(5) Conduction inwards from the plexiform zone is by cells that can be called bipolars. They have numerous dendrites in the plexiform zone while the axon either proceeds from the base of the cell or as a recurrent fibre from one of the dendritic processes (Figs. 3 and 5). The dendrites may be in several of the layers or only in one layer. They extend over an appreciable portion of the lobe (1 mm.) and each is thus influenced by a wide angle of the visual field (see legend to Fig. 3). They do not run equally in all directions. Measurements on Cajal preparations show the greatest number and total length of dendrite to be in the vertical direction (Table 1). There are also many horizontal ones, but fewer obliques. The individual fibres are longest in the horizontal direction, and Golgi preparations show that many of the dendritic fields are oval, with the long axis horizontal (Fig. 4). However, others have the main axis vertical or oblique. It may be that where a cell has dendritic fields in several of the plexiform zone layers, these lie predominantly in different directions, as shown diagrammatically in Fig. 3. Since the fields can only be seen fully in tangential sections, it is difficult to obtain evidence on their orientation. That they have some relation to the main axes suggests a possible connexion with the fact that an octopus can discriminate between vertical and horizontal rectangles but not between obliques[11]. Sutherland[12] has provided evidence that octopuses discriminate between visual figures largely by taking account of some function of their vertical and horizontal extents. Cells with dendrites at different depths might be individually

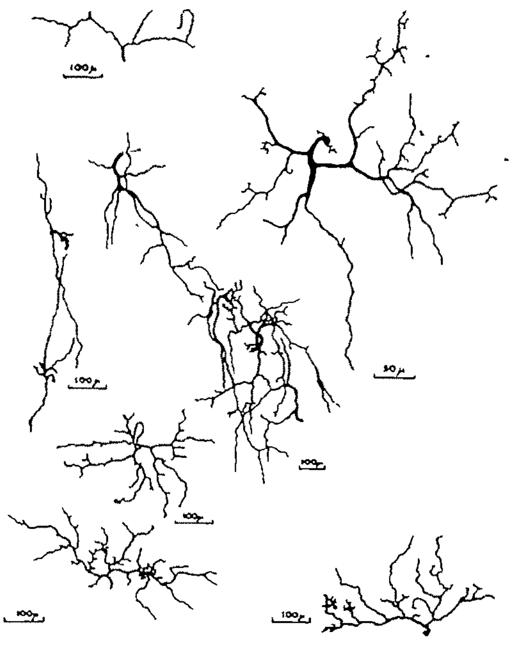

Fig. 4. Drawings of dendritic fields of some bipolar cells in the plexiform layer as seen in tangential sections of Golgi preparations. The fields are oval, with long axes directed mainly horizontally, but sometimes vertically

responsive to different ratios in these directions, if the amacrines ensure that excitation by contours of greater length occurs at greater depths.

(6) However, there is the further possibility that cells deeper in the optic lobes are sensitive to such ratios. Bipolar cells with oriented fields in one plexiform layer only project to depths proportional to the sizes of their receptive fields (Figs. 5 and 6). Here they meet the dendrites of the cells of the medulla of the lobe, the fields of which have most elaborate forms. These are even harder to study than the flatter fields in the plexiform layer, especially as they extend through considerable depths. Some of them have many superficial branches and fewer at deeper levels, others the reverse. If the parts of the field at different depths lie in differing directions these cells might be specifically sensitive to excitation by shapes with particular vertical and horizontal extents

Thus there are undoubtedly regularities in the distribution of the dendrites in the plexiform layer, and this may also be true throughout the lobe. The whole set of some 60 million cells would then provide a system able to learn to make appropriate responses to the vertical/horizontal extent of a moving figure.

The effect of visual stimulation of an octopus by an 'unknown' figure is to elicit attack only occasionally and after long delay[13]. As a hypothesis it is suggested that if food reward occurs following showing of a given shape, the cells that were active become conditioned to produce attack. During the period immediately after presentation, pathways to other parts of the same and the opposite optic lobes and through the vertical lobes would ensure that further cells with appropriate structure become conditioned, in addition to those originally stimulated. This would allow for spread of the representation throughout the tissue and thus for generalization of the response to retinal regions other than that stimulated. Generalization for figures of different sizes might also be achieved in this way, but this requires further investigation. Conversely, a figure that was followed by a shock would come to produce an avoidance response. Learning would thus consist of the accumulation of a sufficient number of suitably conditioned cells to produce a reliable response.

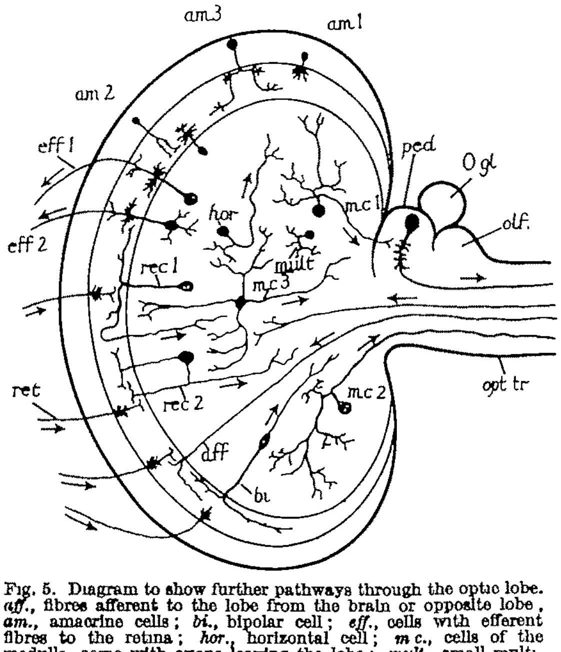

Fig. 5. Diagram to show further pathways through the optic lobe. *aff.*, fibres afferent to the lobe from the brain or opposite lobe, *am.*, amacrine cells; *bi.*, bipolar cell; *eff.*, cells with efferent fibres to the retina; *hor.*, horizontal cell; *m c.*, cells of the medulla, some with axons leaving the lobe; *mult*, small multipolar cell; *o.gl.*, optic gland; *olf.*, olfactory lobe, *opt tr.*, optic tract; *ped.*, peduncle lobe; *rec.*, cells with recurrent axons. All the cells are shown schematically

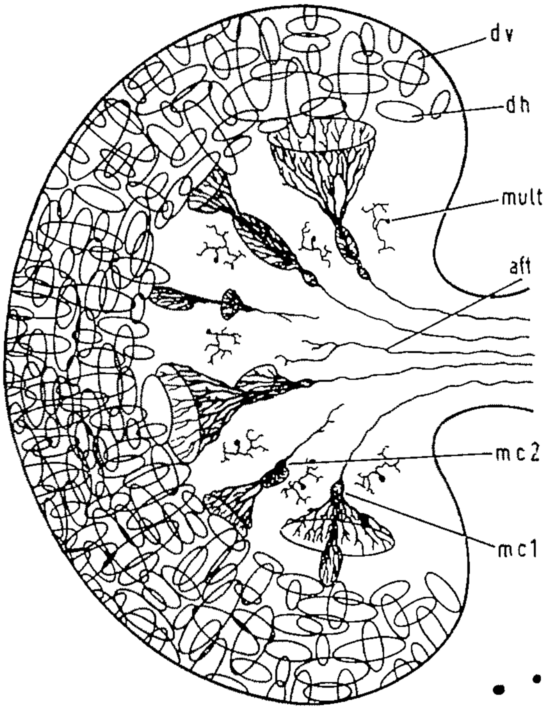

Fig. 6. Diagram of a thick horizontal section of the optic lobe to show probable arrangement of dendritic fields of some bipolar cells in single layers of the plexiform zone. Some run mainly vertically (*d.v.*), others horizontally (*d h.*). The axons of the smaller cells end nearer the surface The cells of the medulla have dendrites at many levels and these may run in different directions at different levels. Very diagrammatic. *aff.*, afferent fibres; *m.c.* 1 and 2, cells of the medulla with deep and superficial dendrites orientated in different directions and spreading to different extents

If the learning of appropriate responses to shapes depends upon the presence of cells with pre-set orientations, then it may be expected that training with several pairs of figures would produce confusions. This proves to be the case. After training in the relatively difficult discrimination between a square and a diamond octopuses discriminated between vertical and horizontal rectangles at a significantly lower level than normal[14]. Other interpretations of this result are possible, and it cannot be claimed that it is proved that the mechanism operates as here suggested. It is interesting, however, that an animal that recognizes shapes largely by their vertical and horizontal extents shows elements in the retina and brain arranged in these directions.

There is a general similarity of the plan of organization of the visual system of *Octopus* with that of insects and vertebrates, which prompts the search for orientation of neuronal fields also in these animals. Indeed, some projections from the mammalian retina to the visual cortex are oval fields each with characteristic orientation[15]. The evidence serves to direct attention to the need for considering the form of the distribution of dendritic fields as a factor allowing coding by selection of particular features of an input.

The research reported in this and the next communication has been sponsored in part by the United States Air Force Office of Scientific Research. We are also greatly indebted to the Nuffield Foundation for continual support and to Dr. P. Dohrn and the staff of the Zoological Station at Naples for their help.

(2) Discrimination of Polarized Light by *Octopus*

By M. F. MOODY and J. R. PARRISS

Department of Anatomy, University College, London

MANY animals, when illuminated by plane polarized light, orient their movements with respect to the plane of polarization. In a recent review Kalmus[1] has discussed the fact that this orientation is not necessarily dependent upon the ability of the animal's eye to analyse polarized light; in many cases the orientation is merely due to brightness patterns in the environment, since the polarized light may be preferentially scattered[2] and reflected in certain directions.

When the experimental results are primarily of ecological interest, the exact mechanism of discrimination is not relevant. However, there is electron microscopical evidence[3,4] to suggest that the discrimination could be performed inside the photo-receptor cells of the eyes, and that it is connected with the orientation of the groups of numerous, parallel, tubular photo-receptor elements inside these cells. To provide evidence on this point it is necessary to show that the discrimination is intra-ocular and to determine whether the retina can give different responses to different directions of the plane of polarization.

In an orientation experiment it is not easy to satisfy either of these criteria. First, it is difficult to illuminate so small a portion of the animal's environment that brightness patterns cannot arise. Second, when the animal orientates itself in a *fixed* direction with respect to the plane of polarization, one is only able to conclude that all other directions give different retinal responses from the preferred direction.

These difficulties can partly be overcome by training an animal to discriminate different planes of polarized light using a modification of the method originated by Boycott and Young[5] in the study of shape discrimination. An octopus, kept in an asbestos tank, was shown a small disk transmitting plane polarized light the electric vector of which could be rotated. When the electric vector was in one direction ('positive') attacks on the disk were rewarded by feeding; when the electric vector was in a different direction ('negative') attacks were punished by giving a mild electric shock.

Table 1

	No. of octopuses	Directions of the electric vector Positive	Negative	Correct responses/ total trials	Correct responses (per cent)
Group *A*	4	↔	↕	571/720	79
Group *B*	4	↕	↔	551/730	75
Group *C*	1	⤢	⤡	143/200	72
Group *D*	2	⤡	⤢	261/400	65

Arrows indicate direction of the electric vectors; the obliques were at 45° or 135° from the horizontal.

Using a two-cell table of χ^2 for equal expected frequencies, the discrimination of each of these four groups is clearly significant beyond 0 01 level.

The light was produced by a small water-tight electric torch, and was passed through a circular sheet of 'Polaroid' (diameter 2·1 cm.) in the rotatable metal front of the torch. The torch lamp voltage was adjusted to give a dim orange light. The octopus viewed the resulting circular disk of light through 3–4 ft. of sea-water. Four groups of animals were trained with different directions of the electric vector. There was evidence of discrimination in each group (see Table 1) but the animals of groups $A + B$ trained on ↕ and ↔ did significantly better than the animals of groups $C + D$ trained on ⤢ and ⤡. (Using a two-by-two contingency table for χ^2, $P = < 0{\cdot}01$.)

It is possible that these discriminations were based on extra-ocular scattering or reflexion patterns (see above), but the nature of the experimental situation leads us to believe that this is unlikely; the variety of discriminations made by the octopus is difficult to explain on these grounds.

It is more likely that the retina is responsible for the discriminations. The receptor cell layer consists of retinula cells and rhabdomes[6], often arranged in rectangular array[7] and lying mainly in the horizontal and vertical planes (see article 1). The rhabdomes contain sub-units, which Wolken[8] called rhabdomeres. He showed that each rhabdomere consists of close-packed fine tubules, almost exactly as in the insect

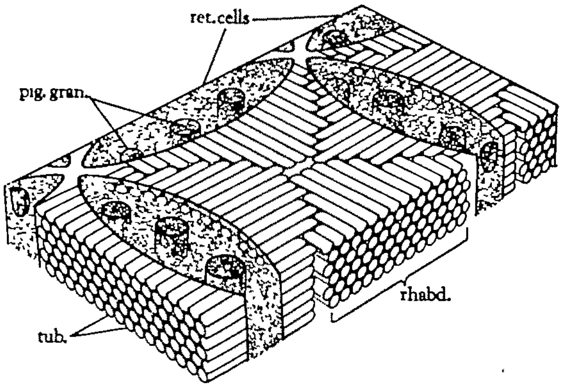

Fig. 1. Tangential section of the receptor layer of the octopus retina; the light would travel vertically from above. The fine tubules (*tub.*) are packed parallel in groups called rhabdomeres (*rhabd.*). The rhabdomeres usually occur in groups of four, each group or rhabdome being bounded by four retinula cells (*ret. cells*). *pig. gran.*, pigment granules. (Semi-diagrammatic; adapted from refs. 5, 7 and 9)

rhabdomeres. Fig. 1 shows the probable arrangement of the tubules in a rectangular rhabdome. The similarity of many structural features in insect ommatidia and in the octopus retina suggests that similar mechanisms might be responsible for the discrimination of polarized light in both cases.

It is proposed to explain the discriminations by postulating the existence in the retina of 'polarizing receptors', each measuring the component of the electric vector in a certain direction (the 'characteristic direction'). Such a receptor might work either by birefringence combined with internal reflexion, or by a dichroic arrangement of the visual pigment molecules[9].

As the simplest hypothesis let us suppose that all the polarizing receptors in the octopus retina have the same characteristic direction. Then unpolarized light would give a response more similar to one of the directions of the electric vector than to the direction perpendicular to it. This possibility was tested, after the discrimination had been established, by showing the octopuses the torch with the 'Polaroid' removed, but with equal brightness. These tests, given without reward or shock, were inserted between normal training trials at regular intervals. Considering the proportion of attacks to non-attacks in each group there was no significant difference between groups *A* and *B* ($\chi^2 = 2\cdot3$) or between groups *C* and *D* ($\chi^2 = 0\cdot10$). This shows that unpolarized light was associated with neither ↕, ↔, ⤢ nor ⤡. The simplest hypothesis is therefore disproved, and it would appear that the retina must contain polarizing receptors with *at least two* characteristic directions.

One possibility is that the receptors have *only two* characteristic directions. This may be connected with the fact that the retinula cells lie approximately in horizontal and vertical planes (see article 1). But if the characteristic directions were to lie exactly in these horizontal and vertical planes, the corresponding receptor cells would be unable to distinguish ⤢ from ⤡, as the component of the electric vector in the characteristic direction would be the same in both cases. One way of explaining how the discrimination of the obliques is possible would be to assume that the axes of the rectangular array are either tilted or at less than 90° ; then the relatively poor discrimination of ⤢ and ⤡ might imply that these distortions would be only slight.

The other possibility is that there are receptors with more than two characteristic directions. The receptors responsible for discriminating ⤢ from ⤡ might be identified with those retinula cells that deviate from the strict horizontal–vertical array. However, it is always possible that there might be no fixed relation between the characteristic direction of the receptors and the orientation of the retinula cells.

(3) Theories of Shape Discrimination in *Octopus*

By DR. N. S. SUTHERLAND

Institute of Experimental Psychology, University of Oxford

THIS article attempts to summarize the results and theoretical implications of a continuing series of experimental studies of shape discrimination in *Octopus vulgaris* Lamarck. The purpose of these experiments is : (1) To discover what are the properties in terms of which shapes are classified by the octopus's brain, and (2) thus to provide evidence to assist in unravelling the neural arrangement in the octopus brain which analyses the relevant properties. Since a property is usually thought of as being either present or absent, whereas shapes resemble one another for a given species to a greater or lesser *degree*, it is more accurate to talk of the *dimension* along which shapes are analysed. This word will be used in what follows, and its meaning will be made clear by examples. Discovering what are the relevant dimensions may be regarded as a first step towards uncovering the neural mechanisms at work : final verification of the existence of a given neural mechanism would, of course, depend upon corroboration from neuroanatomical and neurophysiological studies of brain structure and functioning in *Octopus*.

Two main behavioural methods have been used to provide the data : (*a*) Animals are trained to discriminate between different pairs of shapes, that is, they are trained to attack one member of a pair and not to attack the other. If they discriminate more readily between one pair of shapes than between another, it can be assumed that the former pair exhibits a larger difference on a dimension discriminated than the latter. (*b*) After such training, animals are shown new shapes (transfer shapes), and according to whether they treat these in the same way as the shape they were originally trained to attack, or in the same way as the shape they were originally trained not to attack, it is possible to scale the transfer shapes in degree of similarity to one or other of the original training shapes. Transfer shapes can then be examined, and a dimension sought such that the position of each shape on that dimension predicts the extent to which each shape is treated as like the original positive or the original negative. Examples of such dimensions are absolute vertical extent of a shape, vertical extent relative to area, ratio of vertical to horizontal extent, contour relative to area, number of re-entrants : all these dimensions except the last are continuous.

Two complications need to be mentioned : (*a*) It has been discovered[1] that octopuses have preferences for shapes moving along their long axes and for shapes moving in the direction of their points. Where such shapes are used, care is necessary in interpreting the data since both performance on the initial discrimination and performance on transfer tests are affected by pre-existing preferences. (*b*) It is probable that the octopus can analyse shapes along more than one dimension : this makes the interpretation of results much more difficult since in general any change in a shape introduces changes along several different dimensions.

I put forward[2] a simple mechanism intended to interpret early findings, and to serve as a guide for further research by providing hypotheses for testing. The major purpose of the present article is to examine the original theory in the light of subsequent findings and to indicate current cruxes in the interpretation of the data. The initial findings could, of course, be explained by hypotheses other than that put forward by me: in subsequent experiments some alternative hypotheses have been deliberately tested. Two such alternative hypotheses have now been published by other authors[3,4], and it will be shown that in the light of further data these hypotheses are not tenable. The three theories will first be stated, and then examined in the light of the evidence. It is impossible to summarize all the evidence here: detailed accounts will be found in papers already published and in further papers forthcoming.

Statement of Theories

(*A*) *Vertical and Horizontal Extents.* I suggested[1] that two of the dimensions along which octopuses analyse shape are those of horizontal and vertical extents. A simple neurological mechanism was proposed which counts horizontal extents of a shape at each point on the vertical axis, and vertical extents at each point on the horizontal axis. This converts each shape into its horizontal projection and its vertical projection: such projections are shown in Fig. 1. It is suggested that further analysis proceeds in two ways: (*a*) The ratios maximum horizontal extent to square root of area, and maximum vertical extent to square root of area are computed. (*b*) The two projections obtained may be differentiated so that they are analysed in terms of the direction and size of changes[5]. This means that octopuses will be able to discriminate between shapes which yield a different distribution of vertical extent along the horizontal axis, or a different distribution of horizontal extent along the vertical axis. It must be emphasized that the theory is incomplete at this point in that no attempt has been made to specify exactly how such differences in distribution are analysed. This point will be referred to again below. It is further hypothesized that behaviour is more readily controlled by differences in the horizontal projections than by differences in the vertical projections, possibly because horizontal projections of shapes are more accurately represented in the nervous system. Therefore the discriminability of shapes will be more determined by the similarity of their horizontal projections than the similarity of their vertical projections. In general the theory makes three types of prediction: (1) Shapes having large differences in relative horizontal or vertical extents will be more readily discriminable than shapes having small differences. (2) Shapes which have the same horizontal projections as one another and the same vertical projections will be indiscriminable. (3) Shapes differing only in their horizontal projections will be more readily discriminable than shapes differing only in their vertical projections.

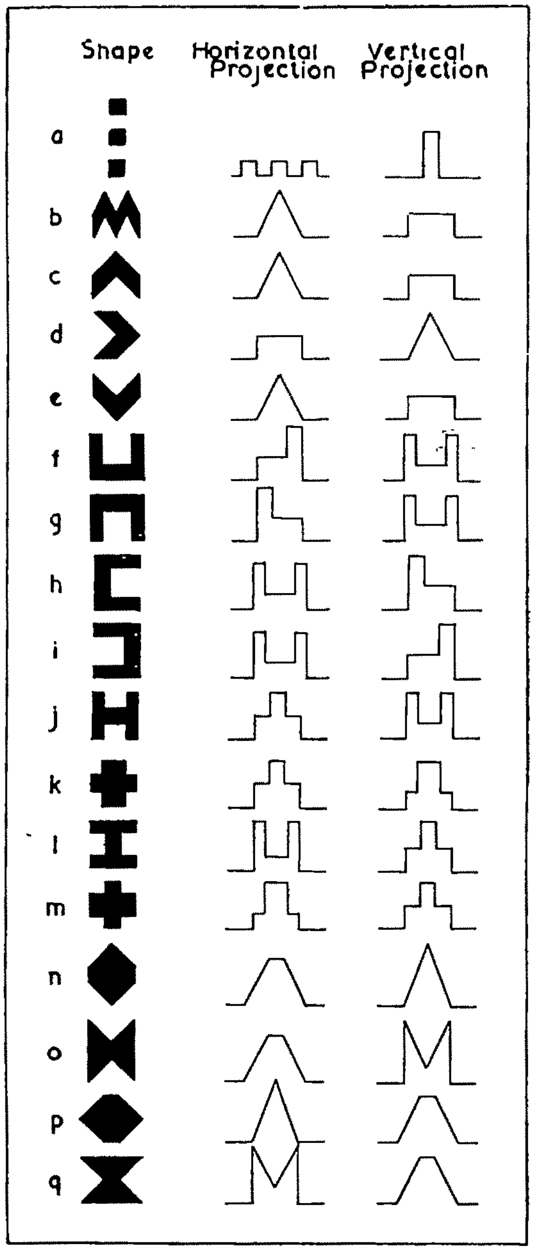

Fig. 1

(*B*) *Vertical Extents between Contours.* Deutsch[3] has proposed a modification of the above theory. He suggests that octopuses count distances between contours in the vertical direction at all points along the horizontal axis. The count is made in such a way that the reciprocal of the distance between contours is taken. All shapes are then scaleable on a single dimension: shapes with small distances in the vertical direction between contours (for example, horizontal rectangles) will be high on this dimension; shapes with large distances between contours in the vertical direction (for example, vertical rectangles) will be low on this dimension. Where a shape contains contours not running in horizontal or vertical directions, it will tend to be high on this dimension since as the contours approach one another the reciprocal of the distance between them will become very large, approaching infinity where they intersect (for example, this will occur at the two basal angles of an isosceles triangle with base horizontal). To prevent obtaining the number infinity from such shapes, it would be necessary to specify some small vertical distance between contours within which no count is made: otherwise the position on this dimension of shapes with contours running in directions other than vertical and horizontal cannot be computed. On general grounds this theory is rather implausible, since it is possible to find a horizontal or vertical rectangle which is at the same point on this dimension as any other shape however complex: it would be difficult to test this prediction, but it seems most unlikely to be correct. (I am indebted to Mr. Sime of this laboratory for this point.)

(*C*) *Direction of Contours.* Dodwell[4] proposed that animals might discriminate between shapes by analysing the direction of their contours with reference to horizontal or vertical. For example, a large response might be given in the nervous system to a horizontal contour and zero response to a vertical with intermediate responses to contours running in intermediate directions. Such an analysis would confuse contours running at, for example, 45° and 135° to the horizontal since both are midway between horizontal and vertical. The theory could be supplemented by assuming that such a count of contour direction was made separately at each point on the vertical or horizontal axis.

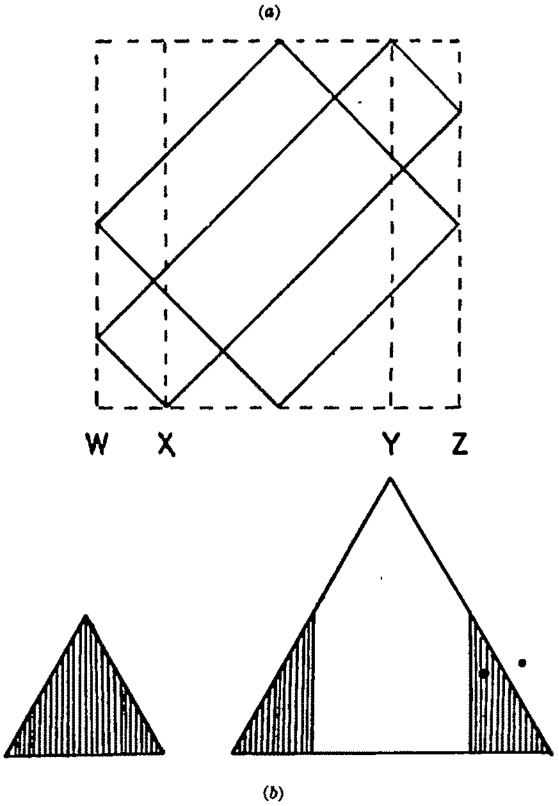
Evaluation in Relation to Experiment

(1) Early findings showed that vertical and horizontal rectangles are very readily discriminable by octopuses, whereas two oblique rectangles in opposite 45° rotations from the horizontal are either indiscriminable or discriminable only with extreme difficulty[6]. Theories *A* and *B* explain this because vertical and horizontal rectangles have large differences in horizontal and vertical extents whereas opposite obliques have none; *C* explains it on the grounds that a horizontal rectangle has much horizontal contour whereas a vertical has little, while two oblique rectangles have the same amount of oblique contour as one another.

(2) The pairs, horizontal and oblique rectangle, and vertical and oblique are both discriminable but not as readily as a vertical and horizontal rectangle[7]. This is predicted by the same sort of reasoning by all three theories. It should be noted that Deutsch's theory (*B*) predicts very poor discrimination between horizontal and oblique since at its extreme left and right sides an oblique has contours approaching one another at a angle of 45° to the horizontal, thus giving very small distances between contours, and therefore when reciprocals are taken placing it high on the dimension analysed: a horizontal rectangle is also high on this dimension. Such poor discrimination was not found, and the difference in performance between animals discriminating vertical and oblique and horizontal and oblique is due to a pre-existing preference for the vertical when moved vertically.

(3) Animals trained to discriminate between a horizontal and oblique treat a vertical rectangle as an oblique, and vice versa[7]. This emphasizes that we are dealing with dimensions rather than properties: on the dimension of 'horizontality' a vertical rectangle differs from a horizontal in the same direction as an oblique (that is, it is less 'horizontal') but it differs to a larger extent.

(4) Animals trained to discriminate between vertical and horizontal rectangles treat the broken vertical rectangle shown in Fig. 1*a* as a vertical rectangle[8]. This is predicted by *A*, since the heights of the horizontal and vertical projections are little changed. *B*, however, predicts that the broken vertical rectangle will be treated as a horizontal since if the reciprocals of distances between contours are counted in the vertical direction, it will yield a large count like the original horizontal rectangle. *C* also predicts that this shape should be treated as a horizontal rectangle, not a vertical. Thus this result supports *A*, but is evidence against both *B* and *C*.



(*a*)

(*b*)

Fig. 2

(5) All theories predict that animals should discriminate better between a square with base horizontal and a triangle than between a triangle and a diamond: this prediction was confirmed[9].

(6) Animals discriminate equally well between the following six pairs of shapes: a square (with base horizontal) versus a vertical, horizontal or oblique rectangle; and a diamond versus a vertical, horizontal and oblique rectangle[10]. This is predicted by *A*, since for all 6 pairs of shapes the difference between amount of vertical extent and between amount of horizontal extent for opposite members of a pair is about the same. It is not clear what theory *B* predicts since some shapes have contours running at right angles to horizontal and vertical axes and some at 45°: as pointed out above it is not possible to say where shapes of the latter kind (that is, diamonds and oblique rectangles) will lie on the dimension under analysis, since at their left and right corners the vertical distance between contours approaches continuously to zero thus making these shapes infinite on this dimension.

The experiment was performed mainly to test a differential prediction between *A* and *C*, since *C* must predict that an oblique rectangle and a diamond will be impossible to discriminate: Fig. 2*a* illustrates how this prediction is made. It will be seen that the diamond and oblique rectangle have two oblique contours at all points on the horizontal axis. The contours are identical between points *W* and *X*, and *Y* and *Z*; between *X* and *Y* they differ only in that one of the contours of the diamond is rotated through 180°. However, since all contours are midway between the vertical and horizontal they should still be indiscriminable. Since this constitutes a crucial test of C, this theory will not be discussed in detail in what follows.

(7) When an animal has been trained to discriminate between a square and a vertical rectangle, it tends to treat a horizontal rectangle as a square (and a vertical as a square if initial training was between a horizontal rectangle and a square)[10]. In terms of the way in which human beings classify shapes this was a surprising finding, but it was predicted by A, since on the dimension under analysis a vertical rectangle differs from a horizontal in the same direction as a square but to a greater degree.

(8) A and B both predict that shapes b and c in Fig. 1 should be indiscriminable: a glance at the projections of these shapes will show that they are the same and therefore should be indiscriminable on A. Since they have the same vertical distance between contours at all points on the horizontal axis they will also be indiscriminable on B. It was found[10] that shapes b and c were in fact barely discriminable whereas c and d were more readily discriminable. Also after training with c and d, b was treated as like c. In addition c and e were found to be indiscriminable, which again is predicted by A and B (cf. the projections in Fig. 1). This experiment thus yields some support for A and B; the reason why some discrimination between b and c occurred will be considered below.

(9) Deutsch rightly points out that B predicts perfect transfer to smaller and larger figures where shapes have contours running in the vertical and horizontal planes: for example, if we halve the linear dimensions of a vertical rectangle we halve the length of contour running in the horizontal plane, but we double the reciprocal of the vertical distance between the two horizontal contours, and thus the smaller shape occupies the same position on the dimension analysed as the larger. However, by changing the size of figures with oblique interior angles, we alter their position on this dimension. This is illustrated in Fig. 2b. The cross-hatched portions of the large triangle are equivalent to the whole of the small triangle: but the reciprocals of distances between contours in the vertical direction in the unshaded central portion of the large triangle must be added, so that the large triangle will be higher on this dimension than the smaller. Thus the theory predicts good transfer to different-sized rectangles, but poor transfer to different-sized triangles. These predictions are not confirmed: there is diminished transfer to all figures including vertical and horizontal rectangles and squares when the area of the figures is reduced by a quarter[6,10]. There is usually better transfer to larger figures, than to smaller, though even this transfer is sometimes less than complete. The results of transfer tests to different-sized figures thus constitute a direct refutation of one of the most interesting predictions made by B.

The reduced transfer found to small shapes cannot be directly explained on any current theory: the most likely explanation is that as the size of the figure is reduced the relative importance of noise in the neural analysing mechanisms may increase, thus giving less-precise representations for such figures.

(10) Up–down mirror image shapes are more readily discriminable than right–left mirror image shapes (for example, shapes f and g in Fig. 1 are more readily discriminable from one another than are shapes h and i)[11]. B cannot account for any discrimination between mirror image shapes of this sort since they fall on the same point as one another on the dimension under analysis. In terms of A the greater ease of discrimination of up–down mirror image shapes than of right–left must mean that behaviour is more accurately controlled by differences in the horizontal projection (on which up–down mirrow images differ; see Fig. 1) than by differences in the vertical projection: this does not confirm the theory since this experiment was run in order to discover whether the horizontal or vertical projection was more important. However, once the theory is modified in this way it yields some interesting further predictions.

(11) One such prediction is that horizontal rectangles of different lengths will be more readily discriminable than vertical rectangles of different lengths (this follows because horizontal extent is more accurately analysed than vertical extent). This prediction was strikingly confirmed[12]. (B predicts equal discriminability.)

(12) A further prediction of the same sort can be made about the two pairs of shapes shown in Fig. 1, j, k and l, m. Since the former pair differs only in vertical projections while the latter pair differs only in horizontal projections, the former pair should be less readily discriminable than the latter. This prediction was not confirmed: both pairs were equally discriminable[13]. A further experiment was conducted with two other pairs of shapes (n, o and p, q), one of which differed only in vertical projections, the other only in horizontal projections: again neither pair was made up of mirror-image shapes. These two pairs were also found to be of equal discriminability[14]. Thus in both cases A yields a false prediction. It should be noted that in these tests, theory B fares even worse than A: not only does it predict better discriminability for the pairs l, m and p, q than for j, k and n, o, it also makes the further prediction that the latter two pairs should be completely indiscriminable, whereas in fact all four pairs are readily discriminated. Pairs j, k and n, o should be indiscriminable on theory B because the two members of each pair have exactly the same total vertical distances between contours, as will be clear from inspection of these shapes in Fig. 1. The reason why these pairs of shapes were in fact readily discriminable although theory A predicts poor discriminability and theory B none will be considered below.

In summary, theory A has yielded consistently correct predictions with the exception of (8) (it predicts no discrimination between shapes b and c whereas slight discrimination was found) and (12) above. Theory B in no instance yields a correct prediction where A fails; in several instances it yields incorrect predictions where A succeeds (4, 9, 10, 11), and in one instance it makes no prediction (6). Theory C yields incorrect predictions throughout with the exception of some of the initial findings. Some slight additional confirmation for A has been forthcoming from Young's work on the neuroanatomy of the optic lobe of octopuses (article 1): there is some evidence that the dendritic fields of pick-up fibres from the input to the optic lobe are orientated primarily in planes corresponding to the visual horizontal and vertical axes. Moreover, there appear to be more fields orientated in the horizontal than in the vertical axis: this would be expected on the theory if the function of these cells was to compute horizontal and vertical extents.

Further Discussion

Because of the large number of correct predictions which it has yielded, it seems likely that *A* is at least along the right lines: it may therefore be worth while appending a brief discussion of some of the current cruxes in the theory.

(1) The major crux arises from the incorrect predictions set out under (8) and (12) in the previous section. The pairs of shapes involved differ from other pairs used in one important respect: the members of each pair differ from one another in the total amount of contour present in each shape. The findings could be interpreted if a second analysing mechanism were present in the octopus which computed the total contour of a shape relative to its area or to the square root of its area. Very extensive transfer tests have been run with some of the shapes involved, and the results give some confirmation to this hypothesis[13,14].

(2) It will be noticed that no attempt has been made to specify how the mechanism which differentiates changes in the projection operates: some such operation as this is necessary to account for findings on mirror image shapes and on squares and circles, squares and triangles, and circles and triangles[9,15]. More experimental work is necessary before a fuller specification can be made.

(3) A further crux is that although most of the results are best fitted by assuming that animals analyse shapes in terms of the ratio, vertical extent to square root of area, there is evidence that in some cases absolute extent is important as well. Thus in transfer tests run after animals had learned to discriminate between horizontal rectangles of different lengths and vertical rectangles of different lengths it was found that animals had been discriminating both in terms of absolute length and in terms of length relative to area[12]. This was established by showing that after the initial discrimination had been learned, animals showed no transfer where these two properties were pitted against one another; for example, if a rectangle was shown which was the same absolute length as the original long one but the same ratio of length to square root of area as the original short one, there was transfer from neither of the original rectangles. This can be reconciled with previous findings if it is supposed that octopuses are capable of analysing both features of shapes (that is, absolute and relative horizontal and vertical extents) but that behaviour is finally controlled by whichever feature gives the biggest difference between the shapes they are asked to discriminate. In previous experiments relative horizontal extent had given a bigger difference between the shapes to be discriminated than absolute horizontal extent (for example, the difference for a horizontal and vertical rectangle with sides in the proportion of 5 : 1 is in the ratio 25 : 1 for relative extent, 5 : 1 for absolute extent, whereas with the rectangles of different lengths used in the experiment under discussion the difference was in the ratio 2 : 1 for both features).

Further experimental work is being directed to the resolution of these three issues. It will be seen that as a theory *A* has proved its usefulness as a guide for the collection of systematic data. Although probably on the right lines, the theory may have to be modified in the light of subsequent neuroanatomical findings. A further method of approach to the problem of shape discrimination is also being explored: systematic data on other species are being collected, and an attempt is being made to correlate species differences in shape discrimination with differences in neural arrangements. In dealing with the central nervous system, this is a promising and previously little-used method for pinpointing the behavioural function mediated by a given neuroanatomical arrangement.

This article was written as part of a project on "Stimulus Analysing Mechanisms": the project is financed jointly by the Nuffield Foundation and by the American Office of Naval Research (Contract *N*62558-2453). I am greatly indebted to Prof. J. Z. Young for extensive discussion of the problems considered in this article.

NEW LABORATORIES AT THE UNIVERSITY OF LIVERPOOL

Chadwick Laboratory

THE Chadwick Laboratory, named after Sir James Chadwick, Lyon Jones professor of physics in the University of Liverpool during 1935–48, was opened to visitors for the first time on April 29 and 30. This Laboratory replaces the George Holt Physics Laboratory, which was opened in 1904 (ref. 1). It has an area of 87,923 sq. ft. and capacity of 1,318,000 cu. ft., and was designed for the teaching of experimental and theoretical physics to undergraduate students, for research in nuclear physics and acoustics, and for postgraduate teaching and research in theoretical physics. The site conditions were such that the most economical plan was to provide piling through to the rock, beneath a bed of pre-glacial peat, for the erection of a framed tower structure at the south end, shown in Fig. 1, with light foundation over the rest of the area for a single-storey structure comprising teaching and research laboratories, and three lecture theatres, one of which can be seen on the extreme right of Fig. 1. The lecture theatres are cantilevered outward from a central service area, a large one on one side, balanced by a medium and a small one on the other, accommodating about 300, 150 and 100 students,

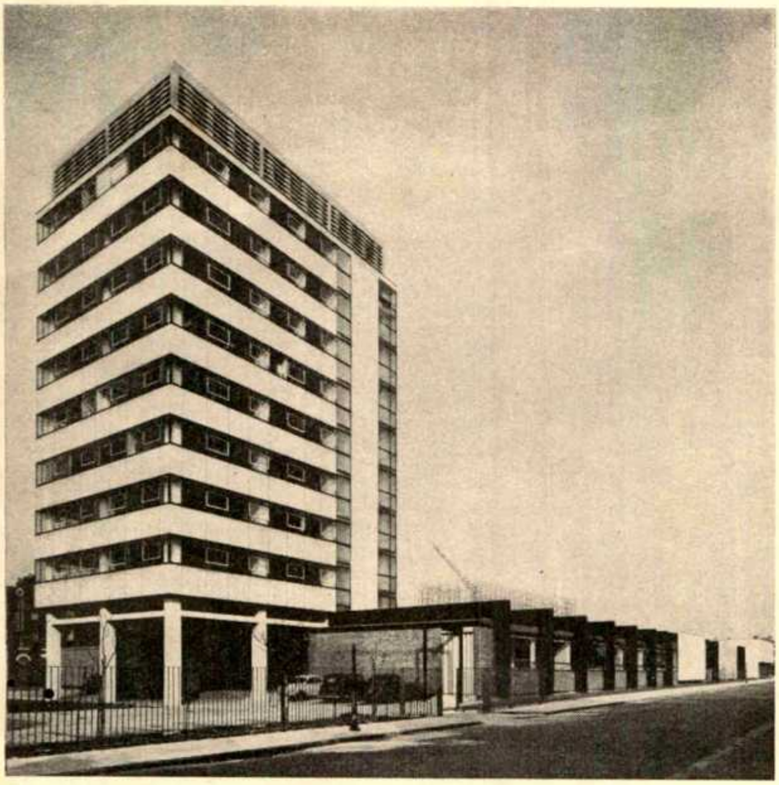

Fig. 1. The Chadwick Laboratory seen from Chatham Street, Liverpool. On the far right the cantilevered lecture theatres

respectively. Artificial illumination and ventilation are used in all three theatres, which have acoustic ceilings and timber-lined walls.

The students' entrance hall, between the theatres and the teaching laboratories, is glass-walled and is approached on each side from the street-level by ramps. The most striking feature of the hall is the mural decoration designed by Geoffrey Clarke.

The six large teaching laboratories, separated by four smaller ones, are constructed in load-bearing brickwork. The ceilings are supported on 40-ft. steel lattice beams placed at 10-ft. intervals. The large laboratories will each accommodate on average about sixty students, and each of the smaller ones about twenty-five.

Similar in style to the group of large teaching laboratories opening off the main corridor is the departmental library. It will accommodate seventy readers and about 5,000 books.

A duct beneath the main corridor connecting the lecture theatre block to the tower carries all the services for the building.

Between the south end of the main corridor and the tower lies the research area, the east side of which is shown in Fig. 1. The research laboratories are mainly of reinforced concrete with columns and deep upstand beams at 20-ft. centres. The outer walls are in grey-brown brickwork with purple brick plinths. Eight rooms, each of approximately 400 sq. ft., are used as preparation rooms for nuclear research, which is carried out in the Nuclear Physics Research Laboratory in Mount Pleasant, some 400 yards away. In the preparation rooms, research groups construct, test and develop apparatus to be used with the 156-in. synchrocyclotron, which has already been described[2], the 37-in. cyclotron, the Cockcroft–Walton high-tension set and the 10-in. diameter liquid-hydrogen bubble chamber, as well as the design and development of a 60-in. bubble chamber for use in the Rutherford Laboratory at Harwell and in the CERN Laboratory at Geneva.

Beta-ray spectroscopy is carried out in a specially designed room of approximately 800 sq. ft. in area, with a small adjoining room for motor generators. One half of the floor, which is of black quarry tile, is reinforced to take a 7-ton magnet. The other half is free from iron so that accurate magnetic field-strength measurements may be made.

The Sub-Department of Acoustics occupies the rest of the research block, which includes, besides a general laboratory of area 1,600 sq. ft., a large anechoic room, a reverberation room, a suite of three transmission rooms and two common control rooms. Facilities are available for work on the propagation of acoustic waves in materials, on aerodynamic sources of sound, on electro-acoustic devices and on communication acoustics, including room and building acoustics.

A modern workshop and a well-equipped glass-blowing room serve the requirements of most of the teaching and research carried out in the Laboratory. The glass-blowing room has floor heating and a means of obtaining diffuse daylight when required. The transfer of heavy equipment in and out of the building is facilitated by the use of three sliding doors opening from the spectrometer room, the workshop and the acoustic block at street-level. That serving the latter may be seen with its loading gantry in Fig. 1.

The 110-ft. tower is a reinforced concrete structure with beamless slabs for each floor supported on twelve columns at 20-ft. centres. The wall cladding is in the form of 5-ft. square pre-cast panels faced in glass mosaic. The eight storeys of this block are accessible by means of two lifts and stairs. The first five stories are devoted to experimental physics and house two large laboratories for the teaching of practical physics to honours students, a reading and writing room, a staff common room, research rooms, administrative and staff offices.

The Department of Theoretical Physics occupies the sixth, seventh and eighth floors of this block. The Department concerns itself principally with post-graduate teaching and research; the only research facilities required are books and journals, and these are provided by an up-to-date library on the sixth floor. Discussions and seminars are held in the discussion room on the seventh floor.

Projecting above the roof-level of the tower are a small observatory and a penthouse containing services. On the observatory is housed a 4½-in. refractor astronomical telescope with an equatorial mounting. The dome is moulded in fibre glass and weighs only 3 cwt.

The part of the site outside the tower has not been completed, owing to the construction of a separate building to house a 12-million volt tandem Van de Graaff machine. When completed there will be a paved courtyard with an ornamental pool in which there will be erected a sculpture of abstract composition by Hubert Dalwood. This sculpture has already been executed and is now placed on a temporary pedestal at the south end of the Laboratory.

The planning of the Chadwick Laboratory was directed by the late Prof. H. W. B. Skinner and Mr. A. M. Hudson Davies, the chairman of the Building Committee.

Civil Engineering and Building Science Laboratories

A PROJECT for the provision of adequate laboratories for the Department of Civil Engineering in the University of Liverpool was frustrated by the outbreak of the Second World War, and during the post-war period the Department had to be accommodated in an old building, originally built for quite a different purpose, until such time as new laboratories could be provided. It is therefore pleasing to note that this has now been achieved and that the inauguration of a new building housing the Departments of Civil Engineering and Building Science was marked during April 29–30 by a series of functions in the University, which was also associated with the opening of the Chadwick Laboratory for the Department of Physics.

The building for civil engineering was designed by Mr. E. Maxwell Fry, and erected by Holland and Hannen and Cubitts (North West), Ltd. It has a total area of 50,275 sq. ft., of which only about 15 per cent is given over to circulation space. Construction commenced on June 1, 1958, and the building was occupied on October 1, 1959; the total cost was £253,144.

The main part of the building is an eight-storey block, roughly *T*-shaped (Fig. 1). This is flanked by a single-storey building containing the Structures Laboratory. From the outside, the most striking feature of the building is a panel some 60 ft. in height which carries in huge concrete letters a selection of names well known to engineering historians, ranging in time from Archimedes to Parsons, and in achievement from Leonardo to Bessemer. The entrance hall gives a pleasing impression of space, resulting partly from a large observation window looking into the Structures Laboratory. The entrance hall has now been further enlivened by a mural in ceramic tiles by Mr. Peter Lanyon.

The largest laboratory in the building, measuring about 100 ft. × 40 ft., is devoted to structural testing. The laboratory is being equipped with a variety of frames for tests on struts, beams, slabs and other elements. A system of steel beams is to be laid on the floor to provide a foundation for test rigs. Facilities for pulsating load tests will eventually be a special feature of the laboratory; a wide variety of equipment for static and dynamic strain measurement is already available. The Concrete Laboratory is adjacent to the Structures Laboratory and is equipped with plant for mixing, placing, vibrating and curing concrete and for tests on this material. Aggregate is stored in a series of bunkers filled from outside the building, and there is provision for screening and drying material used for test purposes.

The Hydraulics Laboratory, also on the ground-floor, has a long section which accommodates a tilting channel 48 ft. in length and a more square area for other hydraulic model work. At present a model of Milford Haven is being constructed for the study of a tidal barrage project, intended to provide freshwater storage for the future needs of that port. A workshop is situated between the Hydraulics and Structures Laboratories and provides facilities for the construction and maintenance of apparatus and the preparation of test specimens of all kinds.

Other laboratories are located on various floors in the main part of the building and include laboratories for photoelasticity, soil mechanics, road engineering, model analysis and municipal engineering. In addition to these rooms there are lecture rooms, drawing offices and other accommodation in the building sufficient for an eventual expansion to final-year classes of sixty students in civil engineering and for a complement of about twelve research students.

The Department of Building Science, which shares the new building, was established in 1957 to promote the scientific study of problems arising in the design, construction and use of buildings. Laboratories for the study of building materials and physics of environment are located on the fifth floor. These

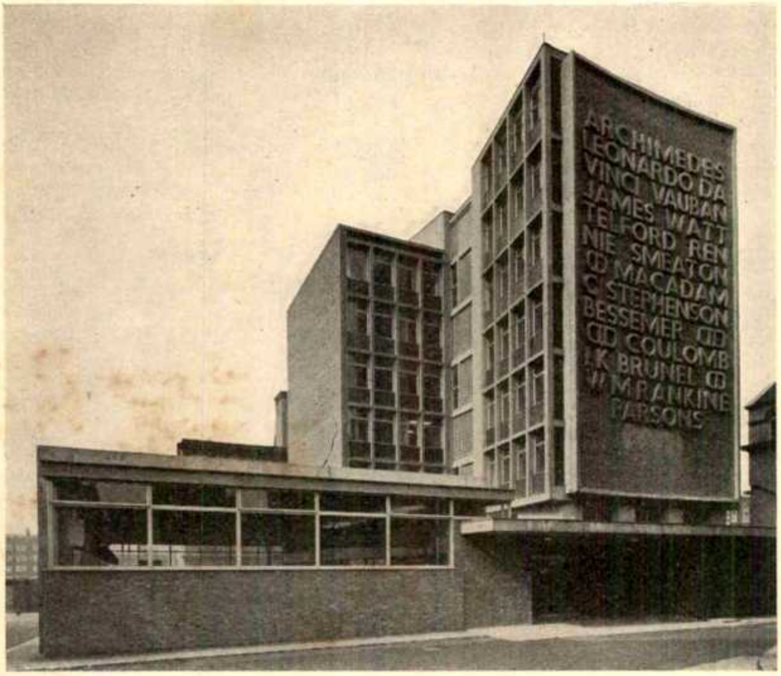

Fig. 1. Civil Engineering and Building Science Laboratories at Liverpool

laboratories are well equipped for teaching and research work in their respective spheres. There is also on this floor a general research laboratory, a study room for research students, a small workshop and a number of staff offices. Although the Lighting Laboratory belonging to the Department is located in another building, there is a photometric room on the ground floor of this new building which is used for the calibration of photo-cells and other equipment used in lighting studies.

An exposure site for studying the weathering of building materials in a polluted industrial atmosphere is being established on the roof, together with instruments for the measurement of meteorological parameters—such as wind, rainfall and radiation—and of atmospheric pollutants. These measurements are, of course, essential for the proper evaluation of the results of weathering tests, and it is intended to obtain continuous records by using suitable recording apparatus.

The Concrete Laboratory, previously referred to, is operated jointly by the Departments of Building Science and Civil Engineering, and facilities are available for the study of building structures in the main Structures Laboratory. Funds have been provided for the construction of a low-speed wind tunnel for studying the wind-flow around buildings in relation to structural, heating and ventilation problems. A controlled-environment room is also to be installed for the study of temperature, radiation and air movement patterns in rooms heated or cooled in various ways.

This new Civil Engineering Building represents the first phase in the building programme for the Faculty of Engineering of the University of Liverpool. New buildings are also projected for other departments in the Faculty during the next few years; their construction will permit the University to make its contribution towards meeting the national need for a greatly increased number of graduates in engineering.

OBITUARIES

Dr. Agnes Arber, F.R.S.

Dr. Agnes Arber, one of the world's most erudite and distinguished plant morphologists, died in Cambridge on March 22. Her contributions to botany were not only original observations of the structure and development of the higher plants, with generalizations based on these observations and contributions to the philosophy of biology, but also studies of outstanding interest in the history of the science.

She was born in 1879, the eldest child of H. R. Robertson, an artist, from whom she inherited the ability shown in the many illustrations drawn for her books and papers. She was educated at the North London Collegiate School, at University College, London, and at Newnham College, Cambridge. In London her work was much influenced by F. W. Oliver and A. G. Tansley; at Cambridge she came under the spell of William Bateson. Leaving Newnham, she worked as research assistant to Miss Ethel Sargant in her private laboratory at Reigate, and later became Quain Student in Biology at University College (1903–8) and lecturer in botany during 1908–9.

In 1909 she married Dr. E. A. Newell Arber, demonstrator in palæobotany in the University of Cambridge, author of many papers and books on fossil plants. From him she obtained both encouragement and training in botanical research. They had one daughter; her husband died in 1918. During 1910–27 she carried on her studies in the old Balfour Laboratory, which then belonged to Newnham College, and afterwards continued in a small room, fitted up as a laboratory, in her private house.

Working very assiduously, her observations covered a wide field; but the monocotyledonous plants were her special interest. The results of her studies were published in more than fifty papers and some books of outstanding merit. "Water Plants, a Study of Aquatic Angiosperms" (1920), "Monocotyledons" (1925), "The Gramineae" (1934), all published by the Cambridge University Press, are models of their kind both for the many beautiful line drawings with which they are illustrated, and for their admirable bibliographies. Plant morphology, from its inception by Goethe, has been intimately bound up with philosophy and metaphysics; but in the present century it has become mainly a study of plant phylogeny. From 1929, Mrs. Arber became increasingly interested in philosophy, and in the more general ideas which have arisen from the study of plant form since the time of Aristotle. From her studies of the literature and her wide knowledge of the facts, she produced one of the most important botanical books of the present century, "The Natural Philosophy of Plant Form" (1950). In this work she gave an account of the history of the ideas about plant form which have occupied men's thoughts since classical times, she explained how the modern confusion of thought had arisen between the older typological outlook on plant form and the modern evolutionary mode of thought. So long as the study of form and structure remains as part of the education of a botanist, this book should remain as an indispensable introduction to such a study.

Her last books were devoted mainly to philosophy, "The Mind and the Eye" (1954) examines the relationship between the eye that sees and the mind that weighs and pronounces. It is a book which was badly needed, especially by biologists who had no philosophical training, and it probably reveals the stages in the author's own mental development. "The Manifold and the One" (1957) was a purely philosophical essay, reflecting the depth and maturity of her mind and the outcome of quiet contemplation.

By many, Dr. Arber will be remembered for her first book, "Herbals, their Origin and Evolution" (1912; second edition 1938), a charming and fascinating book, abundantly illustrated, about the early history of study of plants and the men who worked at it.

When still young she became well known for the excellence of her work, and was elected a Fellow of the Linnean Society of London in 1908, two years after the time when women were first admitted to that Society. She held at different times a Research Fellowship at Newnham College, a Fellowship and a Studentship at University College, London, and a

Leverhulme Research Fellowship. In 1946 she was elected to the Royal Society, and in 1948 received the Linnean Gold Medal from the Linnean Society. Abroad the recognition of her work was shown by her appointment as Corresponding Member of the Botanical Society of America.

H. HAMSHAW THOMAS

Dr. Donald J. Hughes

IT was with sadness and consternation that his many friends learned that Don Hughes had died on April 12 through heart failure at the age of forty-five years.

Hughes's research activity began with cosmic-ray studies in the University of Chicago under Prof. A. H. Compton, followed by an expedition to the Andes, where the change of the slow-meson component with altitude was studied. When war broke out, Hughes joined first the National Ordnance Laboratory and later the Metallurgical Project, assisting in the provision of data relevant to the atomic bomb.

After the War, Hughes joined the Argonne National Laboratory as director of the Nuclear Physics Division, and in 1949 accepted a position as senior physicist at the Brookhaven National Laboratory, which he held until his death. At these Government Laboratories he carried out the research in low-energy neutron physics which made him internationally famous. Hughes's activities in this field fell into three sections: neutron optics, neutron interaction with crystal lattices and liquids, and nuclear physics.

The work with neutron beams from the local reactors yielded three important results. A study of the total reflexion of a neutron beam by a magnetized cobalt mirror gave two critical angles demonstrating the spin $\frac{1}{2}$ of the neutron. Measurements of the angular dependence of intensity agreed with the idea that 'Ampère currents' are responsible for the effective magnetic field of ferromagnets and not dipole–dipole interactions. Next, a compensation method applied to reflexion measurements by various liquid hydrocarbons allowed Hughes to obtain the coherent cross-section of the proton with great precision. This quantity in conjunction with other data is needed to support our belief that the nuclear interaction of the proton–proton and neutron–proton are the same. A slight modification of the same method yielded the basic neutron–electron interaction with better accuracy than obtained previously.

In the solid state field, Hughes was able, by a time-of-flight method, to obtain from scattering experiments with 'cold' neutrons the energy transfer from the lattice to the neutrons. This information permitted a determination in the case of vanadium with the help of formulæ due to Van Hove, of the frequency spectrum of the lattice. His last paper concerned the energy interchange of neutrons with water, showing the existence of discrete levels due to hindered rotation of the water molecule in the field of its neighbours, an interpretation which was supported by Raman spectrum observations. Both examples mentioned open up wide new fields of studies of the condensed state.

Hughes's activities in nuclear physics were manifold. Cross-sections were measured with a chopper or crystal spectrometer, methods invented for the rapid evaluation of resonance parameters, neutron-strength functions and nuclear radii determined and the results compared with the predictions made by theoreticians. Some of the work, such as with fissile nuclei, was required for reactor calculations, some was due to scientific questions which had to be settled.

In all his experiments, Hughes showed a gift for obtaining, with comparatively simple means, novel and reliable results. He had the insight to know what was important and to absorb and exploit theories in spite of their present complexities and the abstract nature of the quantum mechanical formalism.

Besides experimental work, Hughes initiated the collection, evaluation and presentation of a large body of low-energy neutron data, known as the weighty report *BNL*-325, which has contributed a great deal of stimulation to nuclear programmes and is indispensable to all. His clear thinking, ease of expression, and his very great didactic skill in lucidly presenting a complex problem made his papers, and particularly his books, of the greatest value to the expert and the young physicist. I am certain their influence in university teaching, though indirect, was considerable. These same personal properties made him one of the best lecturers among the nuclear physicists, and many 'keynote' addresses were demanded of him at scientific conferences. In view of his popularity as a speaker he acted as lecturer to the U.S. Information Service in many countries in Europe. During 1953–54 he was Fulbright professor at the Clarendon Laboratory, Oxford.

It is unfortunate that death has taken from us this boyish-looking scientist at the very peak of his activity. We shall all miss his optimism and excellence in reporting physics at our meetings and his stimulating intensity on our visits to Brookhaven.

E. BRETSCHER

Dr. C. J. Still

CHARLES JAMES STILL, who died on April 6, was a well-known and well-liked figure in teaching, scientific and industrial circles in Northern Ireland. After being one of the first members of the staff of the Chemistry Department of the Municipal Technical Institute, Belfast (now the College of Technology), he played a considerable part in the development of the Department, and when he retired from his lectureship in 1944 he left behind a large and flourishing group, closely associated with the relevant industries.

Educated in Belfast, Still was first apprenticed to a pharmacist in Bath; he returned to Belfast, however, in 1902, to be first laboratory assistant, demonstrator and then lecturer in chemistry (1913). During this time he had taken a London B.Sc. with honours. Between 1917 and 1920 he worked as a research chemist with the British Dyestuffs Corporation, Manchester, and was then appointed lecturer in bleaching and dyeing in the Applied Chemistry Department of Belfast College of Technology. In research work, in conjunction with the late Prof. H. Wren, he gained a Ph.D. for studies in stereochemistry and, while his interests were mainly in the field of textile chemistry, he also became a member of the Pharmaceutical Society of Northern

Ireland (1927). He was a consultant to many textile firms and external examiner for various bodies in textile and pharmaceutical chemistry.

As the work at the College became more specialized and as the Queen's University of Belfast developed, it became a natural consequence for certain College departments to constitute a Faculty of Applied Science and Technology of the University. Indeed, to the present day, the Applied Chemistry section of the Faculty is also the Chemistry Department of the College. As one of the founder members of the Faculty, Dr. Still played a part in guiding its early development. In this, as in all other fields of his activities, Dr. Still was well liked for his quiet wisdom, and his associates and former students still remark on his gentlemanly bearing and consideration for others. He is survived by his second wife, a son and a daughter.

D. Hamer

NEWS and VIEWS

Chemical Engineering at Birmingham : Prof. F. H. Garner, O.B.E.

Prof. F. H. Garner, who is retiring from the chair of chemical engineering in the University of Birmingham at the end of the present session, has had a distinguished industrial and academic career. After graduating at Birmingham he was awarded an 1851 Exhibition Research Scholarship at the Mellon Institute of Research, Pittsburgh, where he became a research Fellow. On returning to Great Britain in 1921 he became chief chemist at the Agwi Petroleum Refinery at Fawley and later director of research of the Esso European Laboratories. He was appointed to the chair of chemical engineering at Birmingham in 1942 (*Nature*, 150, 545; 1942). Under his leadership the Department of Chemical Engineering has earned a high reputation as a centre of training for chemical engineers. During the past seventeen years the number of undergraduates has increased from 22 to 350, the teaching laboratories have been extended and the facilities for research greatly improved. There are now about sixty postgraduate students engaged in original investigations, mainly on problems of a fundamental character. Prof. Garner's contributions to chemical engineering theory and practice are varied and important. Initially his interests were mainly directed towards problems connected with the petroleum industry, and included some of the earliest systematic studies on 'knock' rating, and on the unit operations of distillation and solvent extraction in petroleum refining. Lately his work has been concerned with mass transfer processes operative in two-phase systems ; in particular he has carried out a detailed analysis of the effects of hydrodynamic conditions on internal circulation and vortex formation in moving drops. Prof. Garner has taken a great interest in the methods of training of applied scientists for industry and has consistently advocated the value of advanced courses of a specialized character in enabling students to make use of the latest scientific and technological innovations. He was awarded the Redwood Medal of the Institute of Petroleum in 1951 and the Melchett Medal of the Institute of Fuel in the same year.

Prof. J. T. Davies

Dr. J. T. Davies, who will succeed Prof. Garner at Birmingham, is best known as a distinguished surface chemist. Although born in Swansea, he took his B.Sc. and M.Sc. in chemistry at Canterbury College, New Zealand. In 1946 he left for England and worked with Sir Eric Rideal at the Royal Institution, taking his Ph.D. in 1949. During 1948–49 he was Bristol-Meyers Fellow and a research associate at Stanford University, California, where he worked with Prof. J. W. McBain. During 1949–52 he was Beit Memorial Fellow for medical research (for physico-chemical investigations of surface effects of biological interest) at the Royal Institution and at King's College, London, with five months at the Institut Pasteur in Paris. He was a lecturer in chemistry at King's College during 1952–55, and since then has been a lecturer in the Department of Chemical Engineering, Cambridge. Dr. Davies's scientific interests have been mainly in the field of surface monolayers, in which he is acknowledged as an authority. Since going to Cambridge he has begun to consider the applications of surface chemistry to chemical engineering problems, where its importance is becoming increasingly evident. His appointment to the Department at Birmingham will ensure the continuation of a vigorous research tradition, and will bring to the teaching of chemical engineering there a first-class mind with a rigorous scientific outlook.

The Kanematsu Memorial Institute of Pathology, Sydney Hospital

The Kanematsu Memorial Institute was founded in 1933 by the shareholders of the firm of F. Kanematsu (Australia), Ltd., and was built as a memorial to Fusajiro Kanematsu and his wife. It replaced the old Pathology Department of Sydney Hospital, and a Research Department was established ; Dr. W. K. Inglis was the first director. In 1936, Dr. Inglis resigned to accept the chair of pathology in the University of Sydney and was succeeded as director by Dr. J. C. (now Sir John) Eccles. Between 1937 and 1944 Dr. Eccles developed a Neurophysiology Research Department in which much fundamental work was undertaken. Dr. F. C. Courtice (now professor of experimental pathology in the Australian National University) succeeded Dr. Eccles, who had resigned to become professor of physiology in the University of Otago, New Zealand. Dr. Courtice formed a unit for the investigation of lymph-flow, lipid metabolism, and the passage of lipids through membranes.

Dr. H. M. Whyte

The Kanematsu Institute has now been divided into the Department of Medical Research and the Department of Clinical Pathology. Dr. H. M. Whyte has been appointed director of the Department of Medical Research and will investigate both fundamental and clinical problems of vascular and renal diseases. Dr. Whyte is a graduate in science and medicine of the University of Queensland. He was awarded a Rhodes Scholarship in 1947 and later a grant from the Nuffield Foundation. He obtained a D.Phil. at Oxford in 1951 while an assistant to the Nuffield Professor of Clinical Medicine at the Radcliffe Infirmary. He is a member of the Royal College of Physicians and of the Royal Australasian College of Physicians, and was formerly director of the Clinical Research Department of the Kanematsu Institute.

Dr. A. A. Palmer

THE Department of Clinical Pathology provides the laboratory services in morbid anatomy, biochemistry, hæmatology and bacteriology for Sydney Hospital. It will be directed by Dr. A. A. Palmer, who has been acting director of the Institute since the resignation of Dr. Courtice in 1958. Dr. Palmer graduated in medicine from the University of Sydney in 1941, and after war service trained as a pathologist at the Royal Prince Alfred Hospital, Sydney Hospital, and University College Hospital Medical School, London. He was appointed senior pathologist to the Institute in 1949. The staff of the Department of Clinical Pathology will be encouraged to undertake surveys and investigations in addition to routine duties.

Science and Mathematics Teaching

WHEN Colonel Alexander Strange suggested in *The Times* of February 6, 1874 (see *Nature*, February 12, vol. 9, p. 277), that a Ministry for Science be established, he was expressing concern, echoed by many of his contemporaries, that the teaching of science in Britain was neither as adequate nor extensive as it should be in the schools of his day. Now, eighty-six years later, the first Minister for Science, Lord Hailsham, has given a public address at a seminar on "Policy for School Science", organized by the Office for European Economic Co-operation; nor, in view of the delay in establishing this post is it surprising that he should be saying the same thing. A lot of heavy water has flowed through a lot of reactors even since the Office for European Economic Co-operation was set up, yet the attempts made to satisfy the voracious hunger of the community for scientists seem similarly inadequate. Now Lord Hailsham is anxious to strike "an ideal balance between specialization and general education". To English ears at least, some hope of the balance being struck depends on the provision of science teachers of calibre. Lord Hailsham agrees that this is the "heart of the matter". "It is almost certain", he continues, "that any serious attempt to clothe with reality the picture of an ideal range of scientific education, suitably balanced and fortified by an adequate background of mathematics, would reveal in every country a serious shortage of science teachers without whom the project, in its ideal form, can be never better than a pipe dream". All sections of industry, the universities and schools will wish him well in the future as he grapples with this shortage.

Atomic Physics in Norway

THE first report (in Danish and English) covering the nine months period, October 1, 1957–June 30, 1958, of the activities of the Nordisk Institut for Teoretisk Atomfysik in Copenhagen has recently been issued (Årsberetning 1957/58 (Annual Report). Pp. 29. København: Nordisk Institut for Teoretisk Atomfysik, 1959). The Institute forms part of the Nordisk Organisation for Teoretisk Atomfysik and is intended in particular to be a gathering place for Nordic physicists, where they may carry out research during long or short visits, and where they may meet and collaborate with colleagues from other countries interested in theoretical atomic physics. Provision is also made for the advanced training of young physicists from the Nordic countries who are admitted on fellowships to work at the Institute. Of the five participating countries (Denmark, Finland, Iceland, Norway and Sweden), Denmark has promised to make available premises for the Institute and to defray the expenses connected with their maintenance. During the period under review, the temporary board of the Institute met three times and elected Prof. Niels Bohr as chairman and Prof. T. Gustafson as vice-chairman. The board dealt with the appointment of staff and the selection of research Fellows, and discussed and approved a draft convention. Prof. C. Møller acted as director of the Institute during the interim period, and on June 30, 1958, the staff consisted of four scientific and two administrative staff. There were ten research Fellows. A detailed list of the lectures and colloquia given by members of the Institute and by invited scientists, together with the titles of papers published, complete the report.

The Ciba Foundation

THE report for 1959 of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research, to which are appended details of the colloquia and symposia held during the year, records as the principal event the tenth Anniversary Symposium on "Significant Trends in Medical Research" (Pp. 52. London: The Ciba Foundation, 1960). It also contains particulars of the four study groups, on the nervous mechanisms of pain and itch, the steric course of microbiological reactions, diagnosis of early cancer of the cervix and virus virulence and pathogenicity, and of the research forum on the shortening of life-span of mammals following irradiation, as well as lists of publications and of periodicals taken by the Foundation's library. Three of the Foundation's conferences were held abroad—in Naples, in Paris and in Buenos Aires—and three new overseas members joined the Foundation's Scientific Advisory Panel: Prof. T. P. Feng, Prof. L. F. Leloir and Dr. M. Roche. The five-year period of special encouragement of research into the fundamental aspects of ageing ended during the year. Two demonstrations were arranged of a new Swiss large-screen colour television system called 'Eidophor' (see *Nature*, June 4, page 773). Four Anglo-French bursaries were awarded by the British Selection Committee and five by the French Selection Committee. The eleventh annual lecture was given on June 26 by Prof. Pasteur Vallèry-Radot on "The Role of Intuition in Medical Research".

The American Philosophical Society

THE Yearbook for 1959 of the American Philosophical Society, of which more than half is occupied by reports from recipients of grants, includes the reports of standing committees (with a list of publications) as well as the list of members and reports on finance (Pp. 779. Philadelphia: American Philosophical Society, 1960). From the Penrose Fund, 175,000 dollars was assigned for research and the 188 grants made are listed together with the 60 grants made with 52,000 dollars from the Johnson Fund, and the 6 fellowships for research in clinical medicine for which 27,000 dollars was appropriated from the Daland Fund. A brief history of the Society adds to the reference value of the Yearbook.

Solid State Electronics

The discovery of transistor action was followed by an explosive growth in the world output of publications devoted to the physics, the fabrication technology, and the applications of the transistor and of related semiconductor devices. There have been parallel though less-spectacular developments in the applications of other solid-state phenomena such as ferrimagnetism, ferroelectricity and electroluminescence, but theoretical and practical progress in the latter fields has undoubtedly been hampered by the difficulties of adequately controlling the materials involved. A new channel for the publication of papers on the applied physics and technologies in all these and related fields has been created by the appearance in March 1960 of the first number of the new bi-monthly international journal, *Solid State Electronics* (Pergamon Press, London, New York, Oxford, Paris). The chief editor is Dr. W. C. Dunlap (United States), who is assisted by Dr. L. Pincherle (United Kingdom), Prof. H. Welker (Germany) and Dr. G. M. Hatoyama (Japan). All the ten papers in the first issue deal with semiconductors, the treatment in most of them being such as will appeal to the device designer and device fabrication specialist, as well as, in some cases, to the user. As stated in the foreword, the new journal is intended to be complementary in treatment and scope to "Physics and Chemistry of Solids", which deals with the more fundamental and theoretical aspects of the fields covered.

Statistics of Petroleum Consumption and Refinery Production in Britain: 1958–59

One hears repeatedly of the plight of British collieries with the limitation of coal consumption, a remarkable situation in the light of the picture that was presented of the coal situation ten years ago. The explanation is forthcoming in a recent informative publication by the Petroleum Information Bureau, which reveals the consumption statistics covering all petroleum products, whether imported or from indigenous sources, as well as substitutes such as benzole and hydrogenated spirit (Petroleum Information Bureau. U.K. Petroleum Industry Statistics relating to Consumption and Refinery Production 1958 and 1959. Pp. 10. London: Petroleum Information Bureau, 1960). The data for the years 1958 and 1959 enable the nature of the increasing use of these products to be recognized. In 1959 the oil consumption in Great Britain rose by 17·5 per cent as compared with the previous year, to reach a total of 36½ million tons. Among the major products, fuel-oil consumption (including that for public electricity generation) again showed the greatest increase, being almost a third greater than that for the previous year and reaching 13,811,874 tons. There was also an increase in the use of motor spirit, which exceeded the figures for 1958 by 7·5 per cent. Deliveries of propane and butane increased by 40·5 per cent, and bitumen used for road-building reached a record annual consumption of nearly a million tons. The remarkable growth in demand for oil in Great Britain during the past twenty years is evident from the following milestones: 1938, 8,990,686 tons; 1948, 12,766,025 tons; 1953, 19,000,000 tons; 1959, 36,500,000 tons (all products). The development must undoubtedly continue and provide a really serious challenge to the more active technological development of the use of coal.

Electronic Computers in Population Genetics

Two recent papers add to our understanding of the frequency and distribution of self-compatible homostyled primroses. When homostyly appears in a population it might be expected to increase to a high frequency at the expense of pins and thrums because of the advantage conferred by self-compatibility. Counts made between 1941 and 1954 by Sir Ronald Fisher of the actual frequencies of the three types in populations near Sparkford, Somerset, have been analysed by W. F. Bodmer (*Phil. Trans. Roy. Soc.*, B, 242, 517; 1960). Populations with only moderate homostyle frequencies showed no significant increase during this time, and others with an initially high frequency showed a decrease. Bodmer demonstrates by mathematical models that these situations can be explained by the high degree of cross-fertilization now known to occur between homostyles, coupled with a possible reduction in viability of the homostyles. Populations thus appear to be protected against the retrograde change from an outbreeding to an inbreeding regime. J. L. Crosby (*Phil. Trans. Roy. Soc.*, B, 242, 551; 1960) has studied the irregular distribution of homostyle frequencies among neighbouring populations. The expected pattern with a centre of high frequency corresponding to the point of origin of homostyly, and decreasing frequencies with increasing distance, does not agree with field observations. The irregularities are attributed to random fluctuation (the Sewall Wright effect), and artificial models which take this into account produce distributions similar to those observed. Both authors have used electronic computers to predict the evolutionary changes likely to occur in a population under given conditions. The ability to simulate a large number of generations in a short time is of great value, and there is little doubt that computers will become of increasing importance in population genetics.

Structural Loading in Factories

Four years ago the Building Research Station of the Department of Scientific and Industrial Research started a series of investigations into the special needs of factory building. This work was undertaken in conjunction with the Midland Regional Board for Industry. Already three reports dealing with separate aspects of this problem have been published, and the latest report, "Structural Loading in Factories", is published for the Department of Scientific and Industrial Research by H.M. Stationery Office, price 1*s*. 9*d*. The floors and roofs of modern factories are expected to accommodate an ever-greater variety of equipment. Much of the production plant, service equipment, transport and goods may be carried by the floor, but a great deal of it is now suspended from above. The resulting loading conditions are not fully covered by existing codes of practice, but failure to make reasonable allowance for them will restrict the adaptability of a building to permit improvement of method or change of product. The information in the report supplements the codes by giving more details of various kinds of load for which provision may have to be made, with some indication of typical ranges of sizes, weight and performance of the equipment concerned. The equipment considered includes that for heating and ventilation, lighting units and power distribution, piping, handling plant, machinery and tools. The information will assist factory managements in assessing their needs as well as designers. The loads to be carried can affect the selection of a site and influence the design of a factory. Where very heavy loadings are necessary, they may be a deciding factor in the choice between single- and multi-storey construction.

New Instruments for Electronic Engineers

The latest edition of the Pye Scientific Instrument Catalogue "N" describes several important new developments and supersedes previous editions. The new developments include a stabilized d.c. power-supply unit with output voltages within the range 0–500 V. (250 m.amp. max. load); a d.c. amplifier (contact modulator); 'Scalamp' double-reflexion galvanometers; new ranges of measuring microscopes and cathetometers; an argon chromatograph with new accessories; and industrial flow-type assemblies and density measuring equipment. The illustrated catalogue is divided into nine sections and covers thirty-two pages. Individual descriptive leaflets of most of the instruments are available on request. The catalogue is obtainable from W. G. Pye, Ltd., Cambridge; prices are not quoted.

Ageing and Research

An account of its investigations into the problems of ageing has been published by the U.S. Department of Health, Education and Welfare ("Research Programmes in Ageing". Superintendent of Documents. U.S. Government Printing Office, Washington, D.C. 15 cents). The growing interest in gerontology is reflected in the announcement that, in addition to the continuing research programme carried out by Government scientists, grants by the Government to medical schools and other private institutions for research in ageing have increased 62 per cent in expenditure over 1959. The investigations conducted or supported by Government departments covered many aspects of ageing in three broad areas: (1) the biological process of ageing; (2) the chronic diseases commonly associated with the aged; and (3) additional health problems of the aged, such as the mental health difficulties growing out of changing cultural demands.

Food-borne Infections

Centralization of food production and distribution and consumption on a mass scale involve an increased risk of spreading food-borne disease. It is essential that measures for the control and prevention of such diseases should be strengthened, not merely in each individual country but also at the international level, since foods are being exported and imported on an ever-mounting scale, and tourist travel is continually increasing. If such measures are to be effective, they must be based in the first place on proper notification of cases of food-borne disease in each country, and on the collation at international level of the reports published by the public health administrations. In addition, thorough epidemiological surveys are required. In a report issued by the World Health Organization of a European Technical Conference on Food-Borne Infections and Intoxications, the various control measures designed to promote the production of pure and safe food are reviewed (Technical Report Series, No. 184. Geneva, 16–21 February, 1959—Report. Pp. 18. Geneva: World Health Organization; London: H.M. Stationery Office, 1959. 1 Swiss franc; 1*s*. 9*d*.; 0.30 dollars). The conference also drew up a series of recommendations on what the physician should do when faced with a case of food-borne disease, on what action should be taken by public health services and laboratories, and on national and international measures for the control and prevention of such diseases.

Strontium-90 Content of British Diet

One of the main objects of the investigations being carried out by the Agricultural Research Council on the radioactive contamination of human food and agricultural land is to provide information on the trend of the level of strontium-90 in the British diet. Some of the foods involved in the survey are produced only at a single time in the year, and consequently the assessment of changes in the average dietary intake is most satisfactorily made on an annual basis. However, the contribution from dairy produce represents some 65 per cent of the total dietary intake of strontium-90, and it is useful to have interim reports on activity-levels in milk, particularly during periods when the rate of fall-out has shown some increase. Report No. 2 from the Council's Radiobiological Laboratory ("Strontium-90 in Milk and Agricultural Materials in the United Kingdom 1958–1959". Pp. 91, 17 tables, 15 figures. H.M.S.O., London, 1960. 5*s*.) gives an account of the changes which occurred in the strontium-90 levels in milk samples, representative of a substantial fraction of United Kingdom milk production, during the period January–June 1959. The report indicates a general rise in levels by about 50 per cent during this period, but notes that "such information as is available for samples collected after June 1959 shows that the values have since decreased". The report also includes the results of surveys on strontium-90 in permanent pastures and animal bones, together with summaries of the results of experimental studies which assist in the interpretation of the dietary trend.

Russian Machine Translation Dictionary

The difference between the Russian machine translation dictionary and an ordinary dictionary is discussed in an article by H. S. H. Massey in *Research* (13, No. 4; April 1960). The principles on which a dictionary for machine translation are based appear to be a combination of the syntactical and semantic analysis approach of the Massachusetts Institute of Technology and the polysemia approach of the Rand Development Corporation. The Russian machine translation dictionary differs from an ordinary one in several ways. First, it is divided into separate units corresponding to the languages to be treated. Each word in the source-language dictionary is given the number of its equivalent in the target-language dictionary; for translation in the other direction the words in the target-language-dictionary are allotted indices showing the numbers of their equivalents in the source-language dictionary. Secondly, the dictionary of each language is divided into a section of monosemantic words and a section of polysemantic words, the monosemantic word section being further subdivided into groups of terms belonging to particular spheres of science and a group of widely used monosemantic words. The third peculiarity of the dictionary is that it contains not only a list of lexical units (words) but also a definite set of grammatical characteristics for each word, which is not fully formalized in ordinary dictionaries. This kind of dictionary also provides a system of relative word values, relating the lexical system of the target-language to that of the source-language. This is closely related to the fact that the dictionary provides 'zero values' for words, that is to say, those cases when a word should not be translated as a separate lexical unit.

Mineralogy in the U.S.S.R.

In an article published in the *Bull. All-Union Miner. Soc.* (88, 609; 1959), V. F. Alyavdin, after giving a review of the present-day reference books on crystallography and mineralogy, such as those of Dana, Hintze, Doelter, Goldschmidt and Groth, as well as all the important periodical publications, suggests the necessity of publishing a special series of reference books, but in this case, dealing only with minerals and crystals found in the U.S.S.R. This, proposed, series is as follows: (1) Mineralogy of the U.S.S.R. (in 12–15 volumes); (2) Atlas of crystals of minerals in the U.S.S.R. (in 3–4 volumes); (3) Chemical composition of minerals of the U.S.S.R. (in 2–3 volumes); (4) Optical mineralogy with determinative tables according to the immersion method and according to Fedorov's method; (5) Crystal-goniometric determinative tables, representing the continuation of the Boldyrev's tables for minerals of lower syngonies. At the end of his article V. F. Alyavdin provides a list of Russian publications dealing with regional mineralogy, since the publication of N. Y. Koksharov's "Materials for the mineralogy of Russia (1853–1891)". This list includes numerous publications on the minerals of the Kola Peninsula, Crimea, Urals, Altai and other regions.

Bio-electric Potentials of Plants

In earlier papers, D. S. Fensom (*Canad. J. Bot.*, 35, 573; 1957; 36, 367; 1958) discussed the possible relationships between the bio-electric potentials in plants and translocation systems, and demonstrated that correlations exist between transport patterns and biopotential patterns. While the evidence did not prove conclusively that transport is due to internally generated electricity, it suggested that the two are closely linked, and that both are related to metabolism. Other investigators have advanced somewhat similar views. In a further paper, Fensom (*Canad. J. Bot.*, 37, 1003; 1959) has considered the phenomenon of the production of continuous potentials across membranes in plant tissues by the circulation of the hydrogen ion. Of the three types of membranes which occur generally in plant cells, lipoid, protein and cellulose, it would seem that a protein-coated grid of cellulose can be envisaged as surrounding the cells. Such a membrane would appear to have the right pore size and properties to allow almost unfettered hydrogen ion diffusion but yet permit intercell biopotentials to be built up. It is pointed out that the most important ion involved in diffusion and in subsequent ion exchange would seem to be the hydrogen (as hydronium) ion, and that tissue can conveniently be divided into general areas of hydrogen ion production or hydrogen ion absorption. The resulting circulation of this ion is explored and discussed in relation to photosynthesis, respiration, protoplasmic streaming, and transport. These ideas are shown to give reasonable explanations for the results obtained in experiments and to resolve certain difficulties related to biopotential studies. They are considered to be useful since they predict some important results which can be experimentally tested, some of which are here given.

Griseofulvin

In his presidential address to the British Mycological Society (*Trans. Brit. Mycol. Soc.*, 43, 1; 1960), Dr. P. W. Brian presented a history of the research into griseofulvin. One is led behind the scenes and given an example of how initial interest and careful choice of materials can play an important part in subsequent developments. The reference list shows that workers in a variety of fields have found it a profitable subject for research. Academic aspects that have attracted attention are its chemistry, leading to synthesis of homologues, its mode of action, reflecting upon the normal constitution and development of fungal cell walls, and its translocation in angiosperms, bearing upon the relationship between molecular structure and ease of transport. The applied aspects recorded centre on its use as a systemic fungicide in the treatment of fungus diseases of plants and animals. Its importance in the growth of the concept of systemic fungicides is well known, and its use in animals, particularly against diseases like ringworm of cattle which are resistant to topically applied fungicides, promises to revolutionize treatment of animal mycoses.

Priapulus caudatus Lamarck

The discovery of *P. caudatus*, which was found for the first time in the Flatford area on March 1, 1958, is announced (*Trans. Suffolk Nat. Soc.*, 11, Part 2; 1959). A single specimen was taken from soft mud just below mean sea-level on the shore of the Stour estuary at Stutton Ness. Afterwards, it was proved to be widespread on both Suffolk and Essex shores of the estuary and occurs intertidally in small numbers wherever there is a suitable substrate of soft mud. No individuals have been taken from the region of lowered salinities above Brantham. In addition to the animals from the Stour, *P. caudatus* has been found in the mud of the large lagoon at Shingle Street in Suffolk and from a similar habitat by the Wade at Hamford Water, Essex. The "Victoria History of Suffolk" (1911) notes that this animal is common in the mud of the Deben at Waldringfield. *Priapulus* is an unusual unsegmented worm. The genus appears to have only slight affinities with other groups of invertebrates and is usually placed in a phylum of its own—*phylum* Priapulida.

CIBA Foundation

The seventy-fifth anniversary issue of the *Journal of the CIBA Foundation*, the publication of the chemical firm in Basle, gives an account of the development of the concern, and also brief historical sketches of the branches of science which are concerned in its processes. The *Journal* is richly illustrated, largely in colour, and although some of the text is in the style of popular journalism, it is on the whole instructive and attractive. The part taken by Basle in the development of science, learning and industry is explained, but the field covered is generally wider, the development of science and industry from early times in many lands being dealt with. The style is in general non-technical. The main interest of the publication is the wealth of illustrative material.

National Research Council of Canada Scholarships

THE National Research Council of Canada has granted 486 scholarships for 1960–61, with a total value of 1,040,000 dollars; of these 423 are for graduate work at Canadian universities. These include 140 bursaries worth 1,800 dollars each, and 283 studentships worth 2,200 dollars each. Awards for study in other countries include 34 special scholarships worth 2,200 dollars each. 27 of these are to be held in the United Kingdom, and 7 in the United States. 29 postdoctorate overseas fellowships, valued at 3,500 dollars for married and 2,700 dollars for single Fellows, have been granted for work in the following countries: 21 in the United Kingdon; 2 in Australia; 2 in France and 2 in Germany; 1 in Belgium and 1 in the Netherlands.

Manchester Literary and Philosophical Society

THE Manchester Literary and Philosophical Society announces the election of officers and committee as follows: *president*, Prof. H. Lipson; *vice-presidents*, Miss A. C. Alexander, Sir Geoffrey Jefferson, Mr. F. G. Glossop, Prof. R. D. Waller; *honorary secretaries*, Dr. G. T. Ashley, Dr. L. Cohen; *honorary treasurer*, Mr. H. Hayhurst; *honorary librarians*, Mr. L. L. Ardern, Dr. W. H. Brindley; *honorary curator*, Dr. J. A. Petch; *council*, Mr. L. Cohen, Mr. A. H. Coulty, Mr. S. M. Milner, Mr. N. G. C. Pearson, Miss M. Pilkington, Mr. M. P. Pariser, Mr. B. Rodgers, Mr. F. C. Toy, Mr. C. E. Young.

The Institution of Metallurgists

MR. W. E. BARDGETT, research manager of the United Steel Companies, Ltd., was elected president of the Institution of Metallurgists in succession to Prof. A. J. Murphy. The following appointments to officers and council are also announced: *president-elect*, Dr. N. P. Allen (National Physical Laboratory); *vice-presidents*, E. A. Bolton (I.C.I., Metals Division), and E. G. West (Aluminium Development Association); *honorary treasurer*, L. W. Derry (Battersea College of Technology); *members of council*, I. Jenkins (General Electric Co., Ltd., Wembley, Middlesex), Dr. A. H. Sully (British Steel Castings Research Association, Sheffield), Prof. C. R. Tottle (University of Manchester) and E. Mitchell (Lucas Group Research Centre, Birmingham).

The Institute of Mining and Metallurgy: Awards

THE following awards of the Institute of Mining and Metallurgy are announced: *Gold Medals*, to Mr. E. D. McDermott, in recognition of his services to the mining industry and profession, and of his services to the Institution as its representative on the Governing Body of the Imperial College of Science and Technology for fifteen years; and to Mr. J. Kruttschnitt, in recognition of his services to the mining industry in Australia; *Honorary Membership*, to the Right Hon. Lord Robins, in recognition of his services to the mineral industry, particularly in southern Africa; to Sir Patrick Linstead, in recognition of his services to the profession of mining and metallurgical engineering in the field of education; and to George Augustus Whitworth, in recognition of his services to the mining industry and profession on the occasion of his retirement from the principalship of the Camborne School of Metalliferous Mining.

Announcements

DR. GERALD B. COOK has been appointed chief chemist of the International Atomic Energy Agency. Dr. Cook, a graduate of the University of Birmingham, has worked at the Cavendish Laboratory, the Canadian atomic energy project in Montreal and at Chalk River, and at the Atomic Energy Research Establishment at Harwell, first in the Chemistry Division and from 1954 as head of the Chemistry Group of the Isotope Research Division.

THE Challenger Society is prepared to make small grants for research in marine biology or oceanography at a recognized laboratory during the year June 1960/61. Applications, accompanied by details of the proposed research, should reach the Hon. Secretary, Challenger Society, National Institute of Oceanography, Wormley, Godalming, Surrey, not later than June 30.

"THE Register of Current Scientific Research at South African Universities, 1959" is based on replies to questionnaires, and the 587 entries are printed as received, English translations being provided for Afrikaan entries (edited by D. Ryle Masson. Pp. vii+113. Pretoria: South African Council for Scientific and Industrial Research, 1960). The material is arranged under nine main headings, with sub-divisions, and in the sub-divisions under the university alphabetically. The Register is well printed and most entries are provided with a brief description of the scope of the research. There are author and subject indexes.

A BOOKLET published by the Biochemical Society, copies of which are obtainable from Mr. R. E. Sherriff, 133–5 Oxford Street, London, W.1, explains for the benefit of school-leavers what biochemistry is about, how one can train to become a biochemist and the opportunities and prospects that exist for a biochemist (Careers in Biochemistry. Pp. 8. London: Biochemical Society, 1960. 8*d*.). Some of the information has already appeared in the publications, "Biology as a Career" and "Looking to Chemistry for a Career", of the Institute of Biology and the Royal Institute of Chemistry, respectively, and to these publications prospective biochemists are referred for fuller information.

"CIVILIAN Application Releases through 1959", issued by the Technical Information Division, Sandia Corporation, gives a cumulative bibliography of technical reports, memoranda and manuscripts, including a section on engineering materials (drawings and specifications) released from the Atomic Energy Corporation's Engineering Materials Branch at Oak Ridge (pp. 88. Washington, D.C.: Office of Technical Services, Department of Commerce, 1960. 2.25 dollars). Prices for printed, or photostat, or microfilm copies are listed for many of the entries. There are some 900 entries arranged numerically.

THE INTERNATIONAL ATOMIC ENERGY AGENCY

ASSISTANCE PROGRAMME

IT was decided at a recent session of the Board of Governors to the International Atomic Energy Agency to supply twenty scientists and legal experts, who would assist and advise in various projects being developed, to ten countries. This decision was taken when the Board of Governors was allocating 60 per cent of the Agency's own technical assistance fund for the current year. The countries to receive such support are Afghanistan, Austria, Brazil, Iran, Iraq, Korea, Philippines, Turkey, Venezuela and Yugoslavia. Of these countries, Austria, Iraq, Philippines and Yugoslavia will receive equipment to a total value of 47,200 dollars in connexion with the work to be undertaken. The allocation was made on the basis of requests for assistance under the 1960 programme received by the end of January, the remainder of the funds being left for requests received by the end of May. In addition, the Agency implements an assistance programme under the United Nations Expanded Programme of Technical Assistance.

Afghanistan

Progress in the nuclear development field in Afghanistan has been retarded by a lack of trained personnel and training facilities. Since experience in these fields is very limited in Afghanistan, the Government has requested the International Atomic Energy Agency to provide the services of a nuclear physicist to assist in drawing up a programme; he will also train staff and lecture at the Faculty of Science in the University of Kabul, and assist in establishing a nuclear physics laboratory within the University.

Austria

One biochemist will work at the Austrian Cancer Research Institute in Vienna to advise on the use of radioisotopes in cancer research and on the establishment of a radioisotope laboratory. He will train Austrian scientists in the techniques of determining the distribution of labelled tumour cells in experimental animals. The Agency will also provide some nuclear equipment for this project.

Brazil

One expert in prospecting for nuclear raw materials will visit Brazil to assist the Government's prospecting programme. He will also assist in organizing field training of geologists and prospectors. The Brazilian authorities plan to co-ordinate the country's activities in the field of radioactive minerals and prospecting. The Agency will provide the services of a nuclear geologist to assist in this project, and particularly in planning and organizing a large-scale geological programme.

In connexion with creating a division of nuclear metallurgy at the Institute of Atomic Energy in São Paolo, a nuclear metallurgy expert will be sent to Brazil. He will advise on the organization and working plans of metallurgical laboratories, on the training of specialists and on the co-ordination of work with other institutions in Brazil.

Another expert will work at the Institute of Atomic Energy at São Paolo and assist in training chemists in radiochemistry and isotope separation as applied to the production of radioisotopes. He will also be concerned with the organization and preparation of the research programme of the radiochemical laboratories, and assist in the activities of the Research Institute at Belo Horizonte and other research organizations in Brazil.

The Government of Brazil plans to work out legal rules on third-party liability and insurance for nuclear hazards in connexion with its nuclear power programme, and particularly the Mambucaba nuclear power project. A legal expert will be sent to Brazil to advise the authority for the Mambucaba project on these questions.

Iran

The National Iranian Atomic Energy Commission and the Ministry of Industry are conducting a thorough exploration of Iran's radioactive mineral resources and a survey of the possibilities of mining and producing uranium in the future. Two experts from the International Agency will be attached to this project. One of them will work at the Prospecting Section of the Geological Department of the Ministry of Industry and Mines and advise on organization and methods of radiometric surveys and give further training to the staff. The second expert will work at the Mining Section of the same Department and will assist in installing uranium ore processing equipment and instruct laboratory staff in methods of testing and processing uranium ores as well as in geochemical methods of prospecting for uranium.

Iraq

Two experts, one in the agricultural and one in medical applications of radioisotopes, will visit Iraq, and some equipment will be supplied.

One expert will work on investigations into soil reclamation, fertility surveys and crop improvement; he will also supervise the establishment of an agricultural radioisotope laboratory and direct the research work in the laboratory on soil–plant–water relationships.

The expert in the medical application of radioisotopes will work at the Radioisotope Department of the Republic Hospital in Baghdad and train new Iraqi staff in the medical uses of radioisotopes, in particular in their diagnostic and therapeutic applications.

Korea

The Korean authorities have established an Atomic Energy Research Institute near Seoul, where a swimming-pool reactor, *Triga Mark II*, will be put into operation during 1960. In connexion with the reactor project, the Government of Korea will be assisted by an Agency health physicist, who will advise on all health physics matters relating to the project.

Philippines

A radiochemist will be sent to the Philippines to advise the Atomic Energy Commission on the organization of radioisotope courses and on the radiochemical facilities of the reactor to be built at the projected nuclear research centre near the University of the Philippines.

The International Atomic Energy Agency will also provide some equipment, including counters, ionization chambers, rate-meters and other instruments.

Turkey

An expert in atomic energy planning will go to Turkey at the request of the Government to advise it on working out a detailed long-range atomic energy programme, on the establishment and operation of the necessary facilities and laboratories to implement this programme and on the setting up of new training and research centres.

A research and training reactor is under construction near Istanbul. To elaborate a detailed and effective research and utilization programme for the reactor the Turkish Atomic Energy Committee has established a committee of scientists and requested the International Atomic Energy Agency to provide the services of an expert on reactor utilization to assist in the activities of the Committee. In addition, the expert will advise on setting up and utilizing a sub-critical assembly in the Faculty of Science at the University of Ankara.

Venezuela

A legal expert will be sent to Venezuela to advise the Government on legislative and administrative problems relating to its atomic energy programmes, and assist in planning and drafting the required legislation as well as in training Venezuelan staff on legal matters.

Yugoslavia

An expert in the agricultural applications of isotopes will work at the Yugoslav Institute for the Application of Nuclear Energy in Agriculture, Veterinary Sciences and Forestry in Belgrade. He will assist in equipping the Institute and in the organization and development of a laboratory. To assist the expert in his work and to help in setting up the laboratory the Agency will provide counting and dosimetry equipment.

An expert in the medical uses of atomic energy will be sent to Yugoslavia to initiate clinical research work at the medical radioisotope laboratories in Belgrade, Ljubljana and Zagreb. He will also lecture on the applications of isotopes at a course organized by the Federal Nuclear Energy Commission and advise the Commission on future activities related to the medical applications of radioisotopes.

One biochemist will be attached to the Institute for Biology at Zagreb to help its staff to fight fasciolosis, a cattle disease which is estimated by the Government to cost Yugoslavia 8,000 million dinars annually. He will assist in equipping the radioisotope laboratory of the Institute and train the local staff in the applications of tracers to research. Some nuclear laboratory equipment will also be provided.

THE RESEARCH ASSOCIATION OF BRITISH FLOUR MILLERS

NEW LABORATORIES

CONSIDERABLE extensions to the laboratories of the Cereals Research Station, provided by the Millers Mutual Association, and which include new analytical and research laboratories, animal unit, workshop, committee, lecture and common rooms and canteen, were opened by Lord Rank on May 4. In his speech, he said that there was no need now to remind any industrialist that to be successful he must have the best scientific advice and stimulus at his elbow. While individual milling companies had their own scientific units, the industry looked to the Research Association for leads on major scientific developments; the Research Association was, in fact, the scientific headquarters of the milling industry. After stressing the importance of nutritional research, he went on to say that in Great Britain we had the best and probably the cheapest bread in the world, and in this achievement the Research Association had played a big part. He could say this with authority, because he was president of the Association during 1930–52.

At the luncheon that followed, the president, Mr. L. Hector Read, proposed the health of the guests. Before doing so, he thanked Lord Rank and his colleagues for providing the additions to the laboratories and he also expressed the indebtedness of the Research Association for the great help and encouragement received from the Department of Scientific and Industrial Research during the thirty-seven years since the Association was founded. In welcoming the principal guest, Lord Cohen of Birkenhead, he spoke of him as a leader in his profession, as one who has always been keenly interested in scientific and medical research, and as the outstanding medical statesman of the age. In replying, Lord Cohen pointed out that biology, of which medicine is simply an aspect, had advanced mainly by the application of physics and chemistry to the elucidation of complex biological phenomena. For this reason it was to him of immense significance to see such application being made by the Research Association to the problems of cereals. He noted, too, investigations involving engineering, bacteriology, mycology, entomology, zoology and genetics. With regard to the latter, "Bread and Breed" was indeed a most appropriate title. The æsthetics of bread, its palatability and appearance, and other fields of the arts also entered into the work of the Association, and he wondered whether here in these laboratories would be found the appropriate marriage of the two cultures, science and art, of which Sir Charles Snow spoke recently.

The laboratories were afterwards opened for inspection, and a number of demonstrations were given illustrating the current research programme. These included the structure and chemistry of the

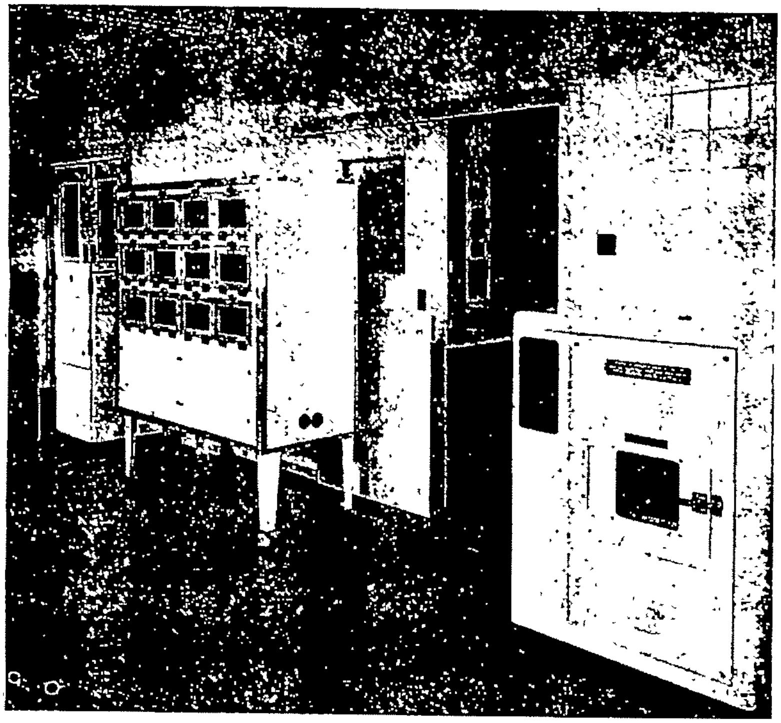

Fig. 1. Corner of Bread Bakery, Cereals Research Station, St. Albans, leading to the Constant Temperature Laboratory

wheat grain, with the distribution of the B vitamins and vitamin E, varietal differences in wheat and how they affect milling and baking properties, the chemistry of the wheat proteins, nutritional studies on wheat and flour as shown by experiments on the rat, experiments on dental caries, the chemistry of cereal lipids, certain aspects of flour milling technology, including the air classification of flour, rheological studies on dough, problems specific to oats and oat products and the avoidance of rodent contamination of cereals on the farm.

To mark the occasion, a book was prepared, entitled "The Research Association of British Flour Millers, 1923–1960", which includes abstracts of the 376 scientific and technical papers published by the Association. The abstracts are grouped in three categories—basic, agricultural and technological. In the introduction, the president writes: "Speaking for my Council, I would like to stress that in our opinion the main function of the Research Association is to carry out basal research. I would add, too, that in our experience the practical results that have followed amply justify this policy. That does not mean that some routine and *ad hoc* work is not necessary. It is, if only to keep the staff in touch and in sympathy with millers' day to day problems. Nor has research on flour milling as such been neglected. I have only to refer to our recent work on the separation from ordinary flour, by air classification, of fractions rich or poor in protein. This may be a major development in the history of flour milling. I believe therefore that the Research Association has for some years struck about the right balance between basal and applied research". T. MORAN

NATURE AND EXPLOITATION OF CROP PLANT RESISTANCE TO DISEASE

A SYMPOSIUM on the nature and exploitation of crop plant resistance to disease, organized jointly by the Association of Applied Biologists (president, Dr. R. V. Harris) and the British Mycological Society (president, Mr. E. C. Large), was held at the London School of Hygiene and Tropical Medicine during January 8–9.

The first day's proceedings were devoted to studies on the host plant, and, in a general introduction, Dr. G. D. H. Bell said how much he appreciated the initiative of the sponsors in arranging this important symposium. The efficient exploitation of disease resistance required the collaboration of both the pathologist and the plant breeder. Obviously the breeder tended to be more concerned with the host than with the pathogen, and although it was accepted as sound breeding policy to handle disease resistance in much the same way as other breeding characters, the genetics of the pathogen had to be considered as well as that of the host. Disease resistance was, of course, expressed in different ways, while various systems of genetic control were known. Major gene resistance in the host had been exploited extensively, but that based on minor genes was undoubtedly safer in many circumstances.

Dr. R. C. F. Macer (Plant Breeding Institute, Cambridge), who considered developments in breeding disease-resistant cereals, suggested that the problems were for the first time being dealt with adequately in Great Britain. The synthesis of wheat lines with genes for resistance to *Puccinia glumarum*, *Erysiphe graminis* and *Cercosporella herpotrichoides* were given as examples of progress being made; in some cases it had been found desirable to use sources of resistance found in allied species and genera. The closed-flowering character of barley was described as an escape mechanism giving protection from all races of *Ustilago nuda*.

Some of the difficulties in breeding for resistance to certain diseases in vegetable crops were outlined by Dr. J. C. Haigh (Wellesbourne), who described the present position in lettuce with regard to mosaic disease, downy mildew (*Bremia lactucae*) and mould (*Botrytis cinerea*). He also referred to the difficulties of using *Lycopersicum pimpinellifolium* and *L. hirsutum* as sources of resistance to *Cladosporium* *fulvum* and *Didymella lycopersici* in breeding outdoor tomatoes.

Dr. R. L. Knight, Miss E. Keep and Mr. J. B. Briggs (East Malling) gave an interesting account of the possible control of a disease by breeding for resistance to its vector. *Amphophora rubi* is the aphid vector of several raspberry viruses, and specific genes have been found in the hosts which give resistance to particular strains of the aphid. The authors considered that there was a good chance of the breeding work being able to keep ahead of the aphid for some time to come.

Dr. D. S. Kirkham and Dr. A. E. Flood (East Malling) discussed apple and pear scab, and they described a resistance mechanism based on biochemical differences. Characteristic phenolic substances were found to be present in the two-host species and quantitative differences in these have been demonstrated between resistant and susceptible varieties. Using the sporulation of the fungi (*Venturia inaequalis* and *V. pirina*) as a measure of biological activity, chlorogenic acid was found to have an inhibitory effect. These fungi have a narrow host specialization, and resistance to them can apparently be conferred by one or more major genes.

Another type of biochemical resistance, but in this case acting outside the plant through root exudates, was described by Dr. E. W. Buxton (Rothamsted) in relation to studies with pea wilt resistance. Pea varieties differ in their susceptibility to individual races of *Fusarium oxysporum* f. *pisi* and resistance appears to be associated with inhibition of growth by the root exudates. The exact nature of the exudate is unknown, but it probably took effect in the rhizosphere, acting either directly upon the parasite, or indirectly by first affecting the associated micro-organisms.

Prof. S. C. Harland, introducing the discussion, said that such joint meetings between scientists of different disciplines were long overdue. He believed that the fundamental information necessary in breeding for disease resistance was a knowledge of the breeding system and the genetic architecture of both the host and the pathogen. He felt that it was necessary, on a long-term basis, to recognize the fact that single major gene resistance was less stable than that based on a number of minor genes, and further consideration should be given to the exploitation of types of resistance known variously as field resistance and adult plant resistance. Prof. Harland wondered whether the time had not come to reconsider the use of induced mutations as a practical method of increasing the variability of the host plants.

The papers on the second day were introduced by Prof. D. Lewis, who briefly summarized the ways in which fungal variability may occur: by mutation, by genetic recombination in sexual reproduction, by segregation of nuclei from heterocaryons and by the parasexual phenomenon. Variation in pathogenicity was now known to occur so rapidly that it often seemed capable of overcoming resistance available to the plant breeder, particularly where reliance was placed upon major gene resistance, which exerted vigorous selection upon the pathogens. Prof. Lewis then contrasted the ability of fungi to break down the resistance of plants with their apparent failure to overcome the toxicity of fungicides.

The paper by Mr. A. C. Hastie (Rothamsted) on "Variation in *Verticillium albo-atrum* isolated from Hops" described experiments, using nutritionally deficient mutants, to determine the mechanisms responsible for variation in this imperfect fungus. Mixed inoculum of isolates differing in nutritional deficiencies, when grown on an unaugmented agar medium, resulted in heterocaryon formation. It may now be inferred that a system similar to parasexuality may give rise to novel progeny. This work is at present being extended to include an investigation of the possibility of these mechanisms also being responsible for variation in pathogenicity.

Dr. R. D. Tinline of the Canada Department of Agriculture, at present working at Rothamsted, reported in his paper "Pathogenic and Cultural Variation in *Cochliobolus sativus*" that variation in culture of this fungus was brought about by mutation, by heterokaryosis and by hybridization. He was, however, unable to demonstrate the existence of 'parasitic races' of this fungus; virulent isolates tended to be highly pathogenic on all thirty-six wheat varieties used in the tests.

In her paper "Interaction, or Genetic Recombination, between Potato Viruses *Y* and *C*", Dr. Marion Watson (Rothamsted) suggested that variation in the symptoms produced by inoculation of closely related virus strains may indicate the formation of mixed isolates of viruses. Experiments using potato viruses *Y* and *C*, which are serologically related, and are strains of the same virus, showed that viruses with attributes of both *Y* and *C* could be obtained from lesions produced by inoculating a mixture of viruses *Y* and *C*. Such new strains were obtained only when the viruses inoculated were related strains, and also possibly when the multiplication took place within the same host cells.

Physiological specialization in *Puccinia glumarum* and *Phytophthora infestans* was discussed by Dr. D. A. Doling (National Institute of Agricultural Botany, Cambridge) with particular reference to race surveys. Such surveys supply information upon the number of races present and their relative frequency and distribution in particular areas. The value of the information obtained, however, depends very much on the organization of the actual collections. The identification of races presents problems of selection of suitable differential host varieties and of methods of inoculation and incubation. The most satisfactory host varieties are those containing known combinations of resistance genes.

Dr. C. C. V. Batts (London) gave a historical account of the distribution of physiological races of *Puccinia glumarum* in Britain since 1946. During this period the number of races identified each year has declined, but new biotypes of two races were now important and were associated with the wheat varieties being grown. The system of international trials being carried out in Western Europe were an extension of the race survey technique discussed by Dr. Doling and were useful in determining the distribution of physiological races over a larger area and also in suggesting suitable resistant varieties. The race position in *Ustilago tritici* was discussed in relation to the reactions of differential varieties. The type of reaction produced is apparently dependent upon the location of the mycelium within the embryo.

The problem of resistance to potato blight (*Phytophthora infestans*) was discussed by Dr. W. Black (Scottish Plant Breeding Station). *Solanum demissum* was a valuable source of resistance due to the hypersensitivity reaction, but from 1932 onwards the fungus has produced new races (now numbering at least 20) which could attack seedlings containing the *R* genes from *S. demissum*. However, in addition to the *R* gene resistance, 'field resistance' was also known which is at present effective against all races. The approach now being made is to combine *R* genes with the 'field resistance', which is inherited polygenically, so that varieties could be produced with a high level of resistance to some, and 'field resistance' to all, races.

The final discussion was opened by Prof. C. T. Ingold who, after surveying the various methods used for identifying physiological races of pathogenic fungi, turned to the more genetical aspects of problems. He considered that the importance of the parasexual cycle was not fully appreciated and in the future needed further investigation on a broad front.

This symposium drew together geneticists, virologists, pathologists and plant breeders who were involved in improving the productivity of crop plants. It is to be hoped that this will be the first of a series of such joint meetings in which scientists of different disciplines can consider together topics of common interest. These discussions were, however, particularly opportune as the rapid advances made in microbial genetics, the information collected as a result of expanded breeding programmes and the experience gained in handling resistant varieties in the past decade, need careful integration if the undoubted benefits of disease resistance are to be fully exploited. Although few fundamentally new ideas emerged from the papers it was clear that the complexities of incorporating stable forms of resistance in commercially acceptable varieties were fully realized. There was nevertheless a feeling that, at least for some crops, the future promised an improved standard of disease resistance based largely upon mechanisms controlled by minor gene systems.

R. C. F. MACER

THE DEVELOPMENT OF SCIENCE IN SOUTH-EAST ASIA

A REGIONAL meeting, to discuss problems of organizing scientific research in South-East Asian countries, was held at Bandung, Indonesia, during December 9–12, 1959. It was organized jointly by the Unesco South-East Asia Science Co-operation Office and the Indonesian Council of Sciences, and was attended by senior representatives of the national research organizations or other appropriate bodies of the following countries: Australia, Hong Kong, India, Indonesia, Japan, Malaya, Philippines, Thailand, Republic of Vietnam, and New Zealand. The meeting was inaugurated with an opening address by the Minister of Education, Instruction and Culture of Indonesia, Prof. Prijono, in the National Planning Board building in Bandung, which had been the scene of the historic Afro-Asian Conference in 1955. Prof. Prijono emphasized that the development of science and technology has not always been accompanied by moral progress, and appealed to the delegates to apply their learning for universal development, based on the common needs of man. The president of the Council of Sciences of Indonesia, Prof. Sarwono Prawirohardjo, was elected chairman of the meeting.

The business sessions of the meeting were held in the impressive headquarters of the National Science Foundation of Indonesia. From the outset of the discussions, stress was laid on informality. It was believed that a frank exchange of views would be more beneficial than formal debates on a number of fixed points, and this indeed proved to be the case. The stages of scientific development of the countries attending the meeting varied considerably—some had long-established government scientific research organizations, whereas others had only recently set up such bodies. After a survey of the main features of government research organization in each country, delegates discussed some of the major organizational problems which they faced. One of these was to determine the optimum balance between fundamental and applied research which they should undertake. It was recognized that developing countries have many urgent problems requiring immediate practical solution, and that it is usually easier to persuade governments to provide funds for research which has a definite practical objective. The traditional role of the universities in research is also to undertake fundamental work. Nevertheless, the meeting felt most strongly that it is essential for the health of national research organizations that they should be free to undertake fundamental work as they think desirable, and to approach any applied problem as basically as is necessary.

Another problem was concerned with the proper responsibilities of a national research organization. These, of course, vary with the country concerned. In some countries of the region the national scientific organizations are operating bodies, maintaining their own laboratories and employing their own staff; in others they are co-ordinating bodies advising their governments on development of policy and distribution of funds. The meeting stressed that in either case it is essential that the national scientific organization should have the maximum possible degree of autonomy of operation and in administering the funds provided for it by its government.

The relative functions of universities and national research organizations were also discussed. It is essential that university research should be effective in training students in the practice and philosophy of research, and for this reason governments should be prepared to provide funds for university research without any conditions as to the projects on which they should be employed.

One particularly interesting discussion covered the conditions for attracting and holding good scientists in the service of national research organizations. This is a vital matter, particularly for countries with national organizations in the early stages of development. The meeting placed great weight on the need for providing as liberal employment conditions as possible. Scientists look for autonomy of the organization, and freedom from political interference and rigid departmental control; the provision of suitable salaries and other conditions of service such as adequate equipment and trained assistance; freedom of publication; liberal travel grants and study leave, etc. It was also agreed that it is most important that the management of scientific organizations should be in the hands of scientists.

As was inevitable at such a meeting, the provision of finance and resources for research came in for considerable discussion. It was recognized that the main burden for this falls on governments, particularly in developing countries where the situation is made more difficult because there is little or no industry to provide additional funds. It was suggested that countries providing assistance for developing countries should be prepared to allocate a larger proportion of their aid funds for scientific research. It is essential, however, that a proper balance should be maintained between the provision of training opportunities in the shape of fellowships, etc., and the provision of equipment and facilities. Training is useless if the trainees do not have equipment and facilities available on their return to their home countries; on the other hand, it is useless to provide expensive and complicated equipment if skilled staff is not available to use it properly.

The encouragement of scientific research in developing countries through regional collaboration in such activities as conferences, symposia and training courses was a major topic of discussion. This led naturally to a discussion of the programme of the Unesco South-East Asia Science Co-operation Office, which is already fulfilling such an important role in the region. In relation to the needs, however, its resources are much too limited, and the meeting agreed that Unesco should be asked to make a greatly increased budgetary provision for its work in the area. The meeting agreed that the following activities, which are all urgently needed in the region, could appropriately be undertaken by Unesco: the provision of information on research programmes being undertaken in the region and on facilities for training and technical assistance; the encouragement of symposia on scientific subjects of special interest to South-East Asia; the provision of training courses for technicians, and refresher courses for science teachers; the encouragement of more visits to the region by scientists. The meeting suggested that the Unesco South-East Asia Science Co-operation Office should consider the possibility of arranging a meeting of librarians and documentation experts of the area, and it recommended that the present and proposed programmes of the Office in the fields of science teacher training, marine science research and humid tropics research should be confirmed and strengthened.

The whole conference demonstrated clearly how effective international meetings on a limited scale can be in promoting understanding and friendship. I believe that the meeting will have valuable practical results in increasing active collaboration between countries of the region in scientific matters. Many of them have scientific problems in common, and it was clear from the discussions at Bandung that they face many similar organizational and administrative problems in building up and strengthening their scientific organizations. The Unesco South-East Asia Science Co-operation Office is to be congratulated in taking the initiative in arranging the meeting, and it is obvious from the discussions that it can play a much greater part in the scientific life of the region if it can be provided with greater support. Such increased activity would be welcomed by all countries represented at the meeting.

All the delegates to the meeting would agree that it was a most successful one, and they have carried away with them the happiest memories of the gracious hospitality of their Indonesian colleagues, and the exquisite beauty of the Java countryside.

GUY B. GRESFORD

RECENT ADVANCES IN COCONUT RESEARCH IN INDIA

THE Agricultural College, Vellayani, Trivandrum, was the venue of the first conference of the coconut research workers in India organized by the Indian Central Coconut Committee, Ernakulam. India is the second largest producer of coconuts, a commodity occupying an important place in international commerce. With the advent of the Indian Central Coconut Committee in 1945 and with the establishment of two Central Coconut Research Stations and seven Regional Research Stations in the different coconut-growing States of the country, coconut research has in recent years gained considerable impetus and it was therefore quite opportune that research workers engaged from all over India should meet and discuss recent advances achieved in their field of work. The Conference was held during December 21–23, 1959, and was attended by more than seventy research workers, representatives of the Kerala Department of Agriculture and the Agricultural College, and some prominent coconut growers. Prof. L. S. S. Kumar, principal of the Agricultural College, presided. Some forty-five papers were presented and discussed at the conference.

Eleven papers covered the subjects falling under the purview of agronomy and general plant nutrition. In the first paper, by Mr. M. M. Krishna Marar and Dr. K. M. Pandalai (Kasaragod), the results of observations made in some long-term (40-year) experimental plots on the coconut were presented. The more important of the conclusions drawn were that (1) regular inter-cultivation and manuring are necessary to step up and maintain the yield at high level, and (2) regular inter-cultivation by itself is highly effective in increasing the yields even in the absence of manuring.

The same authors discussed in another paper the beneficial effects of nitrogen, phosphorus and potassium manuring on inducing flowering and bearing in adult non-bearing palms. Messrs. C. M. John and K. Jacob (Bangalore) reviewed the results of the extensive fertilizer demonstration scheme on coconuts carried out in growers' holdings on the west coast of India and established that manuring with the standard dose of 0·75 lb. nitrogen, 0·75 lb. phosphate and 1·5 lb. potassium together with 50–100 lb. green leaves per tree per year resulted in an increase of 35 per cent in terms of nuts, or 44 per cent in terms of copra, providing a net profit of Rs. 88·00 per acre. Miss K. Vijayalakshmi (Kasaragod) dealt with the various factors regarding moisture in soils of coconut plantations and outlined the various steps to be taken to conserve it. Messrs. T. Kailas Rao and T. Srirama Rao (Ambajipet) showed that for the alluvial soils of the coconut areas of Andhra Pradesh, sunnhemp is the most suitable green manure crop. The practices that have to be tackled when introducing coconut cultivation on a large scale in new regions such as Assam were discussed by Mr. P. R. Nath (Kahikuchi).

Certain aspects of the nutrition of the coconut palm were discussed by Dr. K. M. Pandalai and co-workers (Kasaragod). Dr. Pandalai showed that in the disorders or abnormal conditions such as foliar yellowing, chlorotic condition of the seedlings, petiole breaking, barren nut production, etc., met with in the coconut palm, there is a characteristic accumulation of nitrogen, phosphorus and potassium, etc., as compared with healthy tissues, suggesting some disturbance of optimum nutrient ratios, consequent inadequate metabolism and/or impaired translocation. Mrs. C. K. Thankam (Kasaragod) provided relevant data to justify the above general biochemical pattern of nutrient maladjustment in respect of barren nuts. Mr. P. L. Ramanandan (Kasaragod) dealing with the foliar yellowing condition of the palms, showed that it could be ameliorated to some extent by balanced nitrogen, phosphorus and potassium manuring supplemented with micronutrients such as molybdenum, copper and boron. Mr. C. K. Balakrishnan Nambiar (Kasaragod) showed that, in coconut seedlings, growth as well as leaf composition was correlated to a large extent with the composition of the growth medium, and that unbalanced nitrogen, phosphorus and potassium supply decreased growth and vigour and produced characteristic deficiency symptoms. Mr. N. G. Pillai (Kasaragod) traced the changes in the mineral composition of the different parts of the nuts, such as husk, shell, kernel and nut water, in the course of development from the button stage to ripe nut.

Five papers dealt with subjects of botanical interest. Messrs. S. R. Gangolly, T. P. Gopalakrishnan and co-workers (Kasaragod) presented data to show that synthetic growth-promoting substances such as β-indole propionic acid, β-indole butyric acid in suitable concentrations can be used instead of coconut water along with 2,4-dichlorophenoxy acetic acid for arresting button shedding in the coconut and promoting satisfactory growth of nuts. In another paper Messrs. S. R. Gangolly, M. C. Nambiar, Rama Varma and K. M. Pandalai discussed the distribution of coconut pollen in the atmosphere in relation to weather factors such as humidity, maximum and minimum temperature, sunshine, etc. Mr. R. Gopinathan Nair (Kasaragod), in tracing the anatomical development of the coconut fibre, showed that the fibre strands begin to differentiate in the ovary wall of the female flowers four to five months prior to the opening of the spathes, and that they grow for the main part into typical fibrovascular bundles having a few xylem and phloem elements surrounded by a sheath of fibrous cells. Messrs. R. V. Pillai and K. Satyabalan (Kasaragod) in their paper described the seasonal variations in the yield and nut characteristics of thirteen exotic cultivars of the coconut, and showed the existence of inherent variations among them. Mr. Josy Joseph (Kasaragod) in his paper showed that F_2 progeny seedlings of $T \times D$ (open pollinated or control pollinated) were better than F_1 in vigour as judged by vegetative characters relating to growth.

As many as thirteen papers dealt with the different aspects of the investigations on the diseases of the coconut palm. Mr. U. K. Nair and Dr. K. Radha (Kayangulam) presented data to show that manuring and spraying were generally effective in reducing the adverse effects of the leaf disease. Miss T. O. Prasannakumari, Dr. K. Radha and Mr. V. C. Kurian (Kayangulam) dealing with the efficiency of different copper fungicides for the control of leaf disease concluded that Bordeaux mixture, Kirti copper and 'Fungimar' were more effective than the others tried.

Dr. P. Shanta, Dr. K. P. V. Menon and co-workers (Kayangulam) presented four papers dealing with their investigations on the virological aspects of the wilt disease of the coconut palm. In the first paper they presented results that tend to support the virus hypothesis of the wilt disease. In their second paper they described the host-range of the virus, and showed that the virus can be experimentally transmitted to cowpea seedlings by sap inoculation. In another paper Dr. P. Shanta, Dr. K. P. V. Menon and Mr. K. J. Thommen (Kayangulam) adduced evidence to show that chlorosis and flaccidity of the leaves in the diseased coconut palms are only secondary symptoms brought about by the formation and accumulation of toxic materials in the leaves. Dr. K. Radha and Mr. T. S. S. Rawther (Kayangulam) reported negative correlation between the rhizosphere fungi and rainfall conditions in their studies on the influence of seasonal factors on the rhizosphere microflora with reference to the wilt disease in the coconut palm.

A series of seven papers on the chemical studies on the leaf and wilt disease of the coconut were presented by Messrs. E. J. Verghese, M. P. Sankaranarayanan, S. Robert Cecil, M. K. C. Nair and A. S. Mathew (Kayangulam). In the first two papers they reiterated the salient features of observations made on the incidence of the root and leaf diseases of the palms, and provided data which confirmed the earlier findings regarding the accumulation of major nutritient factors in the diseased tissues. Different aspects relating to the changes in the concentration under water-logged conditions, particularly of possible toxic agents such as ferrous iron, aluminium, organic acids, etc., which could injure plant tissue, were discussed in the third paper. The results of soil survey of healthy and diseased coconut gardens to throw light on the influence of soil conditions in relation to the disease formed the subject of another paper. The ineffectiveness of lime, ash and Chilean nitrate to improve the condition of diseased trees was reported in two other papers by Messrs. M. R. Chettiar, E. J. Verghese, P. C. John, P. V. Channey and M. P. Sankaranarayanan. In the last paper of the series it was concluded that cadmium toxicity is not a factor associated with the disease condition of the coconut palm.

Six papers presented results of investigation on the pests of the coconut palm. Messrs. K. R. Mohan Rao and C. Seshagiri Rao (Ambajipet) described the different pests of the palm prevalent in the Andhra Pradesh, and gave an account of the biological method of control adopted by them against *Nephantis serinopa*. Mr. G. B. Pillai and Dr. C. Kurian (Kayangulam) in their work on the insecticidal efficiency of dieldrin concluded that 0·05 per cent is the optimum minimum concentration for use against *Nephantis serinopa*. Reporting the results of several insecticidal trials against *Rhynchophorus ferrugineus* F., Mr. K. Mathen and Dr. C. Kurian (Kayangulam) held the view that both larvæ and adults suffered 92 per cent mortality of grubs at 0·5 per cent and 100 per cent mortality of adults at 0·1 per cent, seven days after treatment, endrine giving best results.

The results of observation on the incidence of the rhinoceros beetle and the extent of damage done by it under field conditions were presented by Mr. C. P. Ramachandran and Dr. C. Kurian (Kayangulam). Detailed studies of *Perisierola nephantidis*, an ectophagous larval parasite of *Nephantis serinopa*, were reported by Mr. J. Antony and Dr. C. Kurian. Mr. K. V. Joseph (Vellayani), based on the work done by him, emphasized the need to exercise caution in the matter of using DDT for large-scale spraying in coconut areas because of the risk involves in adversely affecting the population of parasites and predators that normally help to keep pests under control in Nature.

Other papers were presented and discussed, and some were submitted only. All the papers submitted for the Conference are being printed as a special volume of the *Indian Coconut Journal* (published by the Indian Central Coconut Committee, Ernakulam, South India).

K. M. PANDALAI

MEDICAL RESEARCH IN THE BRITISH CARIBBEAN

THE fifth annual scientific conference organized by the Standing Advisory Committee for Medical Research in the British Caribbean was held at the University College of the West Indies, Jamaica, during April 2–4. The topic for the meeting was the application of the laboratory to problems of clinical medicine. Doctors from the Caribbean islands, British Guiana, British Honduras, the Bahamas, Great Britain and the United States attended. Thirty-five papers were read and discussed. Prof. A. C. Frazer (University of Birmingham) took the chair on the first day.

The first session was devoted to cardiovascular disorders. A number of hospital studies and field surveys were reported from Jamaica, Trinidad, British Guiana and St. Kitts, by Drs. J. A. Tulloch, G. Wattley, H. Hamilton and K. Stuart. Hypertensive heart disease was the most common cardiac cause for hospital admission followed by luetic and then rheumatic heart disease. Acute rheumatic fever was common, and in Trinidad affected the East Indian to a greater extent than the Negro. Cor pulmonale was uncommon in both Trinidad and Jamaica, but was seen with greater frequency in British Guiana. In British Guiana and Trinidad it occurred almost exclusively in the East Indian. No satisfactory explanation of this racial difference was forthcoming. Myocardial infarction was uncommon in all the territories. This was of interest as aortic atheroma is as common in Jamaica as in the United States of America, although coronary artery atheroma is less severe in Jamaica than in the United States. The association of aortic and coronary atheroma with essential hypertension, diabetes, age and sex was discussed by Dr. W. B. Robertson. The importance of heart disease in the general population was illustrated by the report from Barbados of a chest X-ray survey of 3,000 subjects. This showed a 10·7 per cent incidence of cardiovascular abnormality, and a considerable proportion of these had a positive serological test for syphilis. Yaws has not been recognized in Barbados for many years. This stressed the fact that symptomless cardiovascular syphilis may be more common than has been thought and therefore poses an important public health problem. In the discussion of this paper the urgent need for a test, serological or otherwise, that will differentiate syphilis from yaws was stressed.

Hypertension is common and field surveys carried out in Jamaica and St. Kitts were reported by Dr. K. L. Stuart. The levels of blood pressure in St. Kitts were slightly higher than those reported by the Medical Research Council team in South Wales, whereas in Jamaica the figures were comparable to those from South Wales. An investigation into the occurrence of significant bacilluria in the general population was also reported by Dr. Stuart. There was a considerably higher incidence of bacilluria in the hypertensive female, and this increased with parity. The relationship of bacilluria to hypertension was discussed, and the possibility that pyelonephritis was responsible for the greater incidence of hypertension in the elderly female was suggested. A post-mortem study of hypertensive cases reported by Drs. Ling and Stuart did show that renal hypertension was responsible for 50 per cent of the cases, and that chronic pyelonephritis accounted for one-third of the renal cases.

Diabetes mellitus was discussed at the second session. It was pointed out by Dr. J. A. Tulloch that the prevalence of diabetes in Jamaica was a little more than 1 per cent of the adult population, and that only about 40 per cent of the cases were already known to have diabetes. The ætiology was reviewed and was considered to be very similar to that reported from temperate countries. A consideration of the *J* type cases was reported by Drs. D. MacIntosh and J. Tulloch, which indicated that this was not a distinct type, but was a phase in the natural history of the badly treated type II patient. The results of treatment with chlorpropamide were reported from Trinidad by Dr. T. Poon-King. A considerable proportion of his cases responded satisfactorily. The distribution of blood groups in diabetic subjects was also reported from Trinidad. In both male and female cases there was a low incidence in group O. Males showed an excessive group B and females an excess of group A over that occurring in the local population. A study of liver enzymes in human diabetes was reported by Dr. S. J. Patrick. This largely confirmed animal experiments.

On the second day Prof. E. T. C. Spooner (London School of Hygiene and Tropical Medicine) took the chair. Dr. R. D. Montgomery of the Medical Research Council Tropical Metabolism Unit reported that the oxygen uptake per unit of body weight was not reduced even in severe malnutrition. During recovery the increase became much greater and evidence was given that this was related to thyroid activity. Drs. J. C. Waterlow and D. I. M. Picou reported preliminary observations from isotope studies that, in protein malnutrition, the economy of protein is achieved not by a decreased rate of katabolism but by an increased degree of re-utilization. Although the extent of protein synthesis may be reduced through shortage of supplies, the capacity for synthesis seemed in most cases to be unimpaired. The occurrence of magnesium deficiency in malnutrition was reported by Dr. R. D. Montgomery. This paralleled potassium deficiency and supported the concept of a primary loss of intra-cellular constituents. Further investigations into the megaloblastic anæmia noted in malnourished infants was reported by Drs. MacIver and Back. They showed that the cause was a dietary deficiency of folic acid, and vitamin B_{12} was not implicated. Dr. MacIver also reported on the nature of the severe anæmic episodes in sickle-cell disease and showed that these were of two types. In one folic acid deficiency was the ætiological factor and in the other there was an acute aplastic state. A possible relationship of this latter state to preceding infection was suggested. Non-Addisonian vitamin B_{12} deficiency in the adult was reported from Trinidad by Dr. G. Habib. All the cases were Hindus and with one exception they were strict vegetarians eating no eggs, meat, fowl or fish. It was considered that poverty and a vegetarian diet combined to produce this deficiency state.

A field survey on the size of liver in apparently healthy children was reported by Dr. C. G. Miller. Hepatomegaly was found in about 95 per cent of all children under the age of 12 years. Its presence was not related to malnutrition, but the possible role of infection was considered. The autopsy incidence of cirrhosis of the liver, as noted at the University College Hospital of the West Indies, was much the same as in America. One-third of all cirrhosis cases resulted from veno-occlusive disease of the liver. Liver cancer occurred with moderate frequency. This was a more common finding than in Denmark, but was much less common than in Africa. Hepatocellular carcinoma was more common than cholangio carcinoma and occurred particularly in the young adult male.

Virological investigation of human yellow fever cases in Trinidad was reported by Dr. W. G. Downs of the Trinidad Regional Virus Laboratory. The cases noted in 1959 were diagnosed by isolation of virus from the blood and the difficulty of serological diagnosis was stressed. The clinical occurrence of encephalitis in Jamaica was analysed by Dr. R. A. Irvine and it was noted that sequelæ were a common occurrence. The intra-dermal innoculation against Asian influenza was discussed by Drs. M. M. Sigel (Miami University) and L. S. Grant. In their opinion the intra-dermal injection of antigen would engender an antibody response and such a method could well be adopted in an emergency during epidemics before large supplies of suitable antigens became available.

Prof. G. Bras took the chair on the third day. The possibility that the unusual spastic neuropathies seen and reported from Jamaica were related to treponemal infection was considered by Dr. R. D. Montgomery (Medical Research Council). It was argued that the neuropathy could be a late manifestation of treponemal infection, whether venereal or otherwise, and that it could be due to a strain acting as a poor antigenic stimulus, but producing a typical meningo-vascular lesion in the nervous system. A second neurological disorder noted in Jamaica, that of spinal arachnoiditis, was reported by Prof. E. K. Cruickshank and Dr. P. E. Rodgers. The ætiology of the condition was largely unknown, but it had been found that cases seen early in the disease responded well to cortisone administration. An investigation into tropical plants used for medicinal purposes was reported by Prof. Haynes. It had been found that the breadfruit contained γ-aminobutyric acid, and this factor gave rise to a slight reduction of blood pressure in the anæsthetized dog. Other plants had also been shown to contain this substance.

The meeting was brought to a close by Prof. Bras who thanked all contributors and all visitors from the many islands, Great Britain and the United States for attending the conference.

J. A. Tulloch

ABUNDANCES OF THE RARE-EARTH ELEMENTS, LANTHANUM TO LUTETIUM, IN CHONDRITIC METEORITES

By Dr. R. A. SCHMITT, A. W. MOSEN, C. S. SUFFREDINI, J. E. LASCH,
Dr. R. A. SHARP* and D. A. OLEHY

John Jay Hopkins Laboratory for Pure and Applied Science, General Atomic
Division of General Dynamics Corporation, San Diego, California

THE abundance distribution of nuclear species is considered an important requisite for a satisfactory theory of nucleogenesis[1-3]. Compilations of cosmic abundances of the elements have been published by Goldschmidt, Brown, Urey, Aller, Suess and Urey[1], and Cameron[2], and others. It has been found that the relative cosmic abundances vary by a factor of $\sim 10^{13}$, and decrease logarithmically and rather smoothly from the lightest to the heaviest elements.

Rules of relative atomic abundances, for example, regular and smooth decrease in the abundances of those odd-mass-number nuclides which have masses greater than ~ 50, were assumed to be valid for all elements, because it had been observed that the rare-earth elements (lanthanum to lutetium) showed a regular and smooth decrease in their abundances[1]. Since it is well known that the fourteen rare earths possess a high degree of chemical similarity, because of the filling of the 4-*f* electron shell far inside the valence electrons, the rare earths are assumed to have migrated geochemically through time and space as an 'entity'[4]. Consequently, accurate determinations of the abundances of rare earths in primordial matter are required in order to establish empirical relationships among the abundances of elements formed in nucleogenesis.

Noddack, using X-ray spectroscopic techniques[5], has determined the abundances of the rare earths in composite mixtures of chondritic and achondritic meteorites (~ 9 parts of chondrite to 1 part of achondrite in the mixtures); and Minami[6] has used

---

* Present address: Sharp Laboratories, Inc., La Jolla, California.

Table 1. ABUNDANCES OF RARE EARTHS IN THE CHONDRITIC METEORITES: ALLEGAN AND RICHARDTON

Element	Isotope measured	Radioactive isotope	Isotopic abundance[a] (atoms/10^6 Si atoms)		Elemental abundances

[a] Abundances are given for the isotopes listed in column 2. Measurements of the abundances of the isotopes in column 2 were obtained from the radioisotopes listed in column 3. Errors represent the over-all standard deviation error, which is primarily due to counting statistics.

[b] Elemental abundances were calculated by assuming that terrestrial isotopic ratios are identical to meteoritic isotopic ratios. Errors in the elemental abundances may be obtained from the isotopic abundance errors given in columns 4 and 5.

[c] Ratios are expressed as grams of element per 10^6 gm. of meteorite. Errors may be obtained from the isotopic abundance errors in columns 4 and 5.

[d] See ref. 5. Abundances are given only to significant values.

[e] See ref. 6. Abundances are given only to significant values.

[f] See ref. 1. Suess and Urey chose the rare-earth abundances of Minami (see ref. 6) for inclusion in their cosmic-abundance table. The abundances listed in column 12 are the Suess–Urey interpolated values which gave the best fit between lower and higher mass-elements immediately preceding and following the rare-earth elements.

[g] See ref. 2. Cameron chose the rare-earth abundances of Noddack (see ref. 5) for inclusion in his abundance table and normalized the Noddack abundances by fitting the lanthanum and barium abundances in an approximate manner. We have listed the values of Cameron to two significant numbers.

[h] Elemental abundances of cerium were also determined through the neutron-capture reaction Ce-140 (n,γ)32-day Ce-141 and were found to be 0·88 and 0·90 atoms/10^6 silicon atoms for Allegan and Richardton, respectively. These values may be high due to possible contamination. The abundances of cerium are being checked by different chemical manipulations. The abundance of cerium as determined through 33-hr. Ce-143 is considered to be reliable.

[i] Abundances were determined via the 9·3-hr. upper isomeric state of Eu-152^m.

[j] Abundances were determined via the 13-yr. lower isomeric state of Eu-152.

[k] It was calculated that the abundance of Lu-176 may be too high by ~5 per cent, because the Lu-176 abundance was determined through the radioisotope Lu-177, which is produced by two rare-earth neutron-capture reactions in Lu-176 and Yb-176, with the activated radioisotope Yb-177 decaying to Lu-177.

X-ray spectroscopy to ascertain the rare-earth abundances in shales ($\sim 10^8$ yr. old). If meteoritic and terrestrial matter originated from the same process, then the relative abundances of the rare earths in shales and in meteorites should be very similar. By comparing the data of Minami[6] and Noddack[5], it was found that the abundances of the light rare earths relative to those of the heavy rare earths were about eight times greater in shales than in meteorites (see Table 1).

In order to resolve this difference, it was suggested by Hans E. Suess, of the University of California, La Jolla, that the abundances of the rare earths in chondritic meteorites should be accurately determined by using the new and powerful technique of neutron activation.

At the initiation of the present work, chondritic meteorites had been considered by Urey[1] as most representative of the non-volatile primordial matter of the solar system. The feasibility and reliability of measuring the abundances of elements present in concentrations of one part per million or less in meteorites has been demonstrated by a great many geochemists[7].

Abundances of all the rare-earth elements (lanthanum to lutetium), with the exception of the unstable element promethium, were determined in two chondritic meteorites, Allegan and Richardton, by the neutron activation technique. Five-gram samples of the meteorites and all fourteen rare-earth standards (spectroscopic purity grade) were irradiated simultaneously in the General Atomic *Triga* reactor

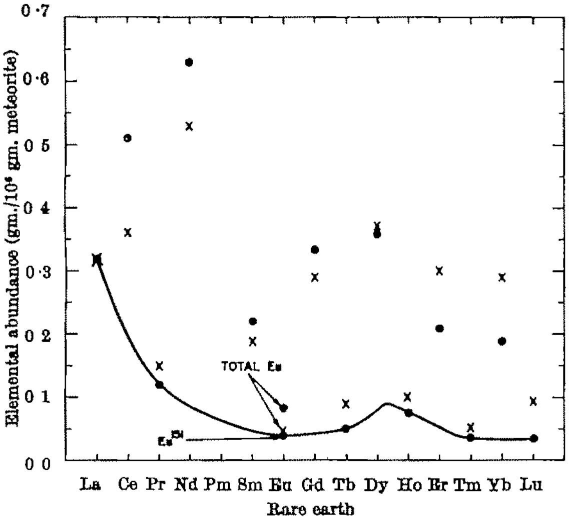

Fig. 1. Average elemental abundances (in gm. of rare earth per 10^6 gm. of meteorite) in the chondrites Allegan and Richardton. Solid circles are values of this work; crosses are values by Noddack (see ref. 5) normalized to the lanthanum abundance of this work. The solid curve connects the odd-*A* abundances of this work. The average standard deviation (*SD*) errors for average elemental abundances of this work are ±9 per cent; Noddack's errors are given as equal to or less than ±4 per cent as *SD*

in a neutron flux of about 2×10^{12} neutrons/cm.^{2}/sec. The meteoritic specimens and the rare-earth standards were placed in separate containers in a rotating circular rack in the reactor, so that all the containers were exposed to the same neutron flux. Subsidiary experiments showed that the neutron spectra were identical (± 3 per cent) in the flux for the pertinent neutron-capture energies in both the meteoritic specimens and in the standards.

After neutron irradiations of about 2 hr., the meteorite samples were immediately subjected to standard radiochemical manipulations in order to separate the activated rare earths resulting from neutron-capture reactions from other activated elements present in the highly radioactive meteoritic specimens. Pure rare-earth carriers in the form of rare-earth oxides were added to the irradiated meteorites before the sodium peroxide fusion of the meteoritic sample. After radiochemical decontamination, the activated rare earths were separated[8] by being passed through 'Dowex 50*W*' × 12, minus 400 mesh, ion-exchange resin. (The resin was especially prepared by Bio-Rad Laboratories, Richmond, California. The settling-rate of the fine resin was 0·5–2·0 cm./min.)

In the determination of the abundances, the final separated rare-earth carriers and the irradiated rare-earth standards were counted in both ordinary and automatically operated well-type scintillation spectrometers, with 1¾ in. × 2 in. sodium iodide (Tl) crystals. Almost all neutron-activated rare earths decay by negatron emission accompanied by gamma emission, and thus lend themselves to γ-ray spectroscopy. It was necessary to count only two of the rare earths by the standard beta-counting method—thulium-170 and erbium-169. Each of the rare earths was identified: (1) by observing the order of ion-exchange elution; (2) by comparing the rare-earth gamma spectra, taken by a 256-channel analyser, with the spectra of the rare-earth standards; and (3) by following the decay of the rare-earth elution peaks and of the rare-earth standards over a few half-lives, either by counting all gamma disintegrations (integral counting), or by counting selected gamma rays of the radioisotopes. The radiochemical yields of the rare-earth carriers were ascertained by comparing the activities resulting from neutron activation analysis of the decayed carriers with those resulting from analysis of a known amount of the individual rare earths.

Results of the determination of rare-earth abundances in the two chondritic meteorites, Allegan and Richardton, are given in columns 1–5 of Table 1. The elemental abundances have been calculated with the assumption of identical isotopic abundances for rare-earth elements in meteoritic and terrestrial matter and are given in columns 6–9 of Table 1. (The validity of this assumption is verified for the rare-earth region by comparing the meteoritic abundance ratios of the isotope pairs gadolinium-158/gadolinium-160, erbium-168/erbium-170, ytterbium-168/ytterbium-174 and lutetium-175/lutetium-176 with terrestrial abundance ratios.) For comparative purposes, the X-ray spectroscopic elemental abundances in meteorites, as determined by Noddack, and in shales, as determined by Minami, are included in the table. Also included are the values given by Suess and Urey[1] and by Cameron[2] in their cosmic abundance compilations.

The average elemental abundances in the chondrites Allegan and Richardton, expressed in grams of rare earth per 10^6 gm. of meteorite (p.p.m.), are plotted in Fig. 1 as solid circles. For comparison, Noddack's meteoritic values (crosses) have been

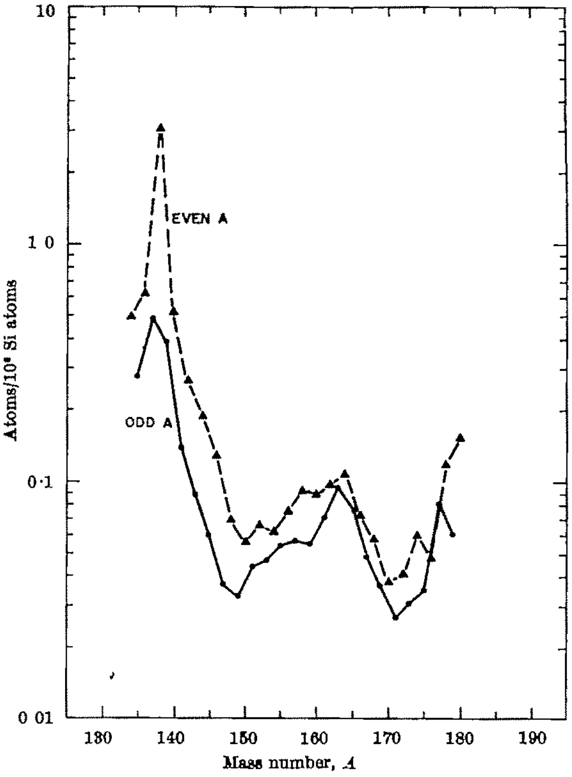

Fig. 2. Average abundances (in atoms per 10^6 silicon atoms of the rare earths) in the chondrites Allegan and Richardton, for both even *A* and odd *A*. Solid circles are odd-*A* and solid triangles are total even-*A* abundances. Solid and dashed lines connect the odd-*A* and total even-*A* abundances, respectively. Average errors of abundances for $A < 176$ are ~10 per cent as *SD*. Errors for $A > 177$ are somewhat indeterminate

included in the figure and are normalized to our lanthanum abundance. A solid curve has been drawn through the odd-mass abundances in Fig. 1.

Again assuming terrestrial isotopic abundances for the rare earths in meteorites, the abundances for all rare-earth isotopes were calculated. These were then used to calculate total isobaric abundances of even A and odd A and were incorporated with the abundances for elements immediately preceding and following the rare-earth group. The abundances plotted in Fig. 2 are the average values for the chondrites Allegan and Richardton and are expressed in units of atoms per 10^6 silicon atom. The elemental abundance peaks at $A = 137$ and 138 were calculated from the recent barium abundance values in 'ordinary' chondrites given by G. W. Reed *et al.*[8]. Values for $A \leqslant 138$ and $A \geqslant 176$ are those of G. W. Reed *et al.*[9], and of Suess and Urey[1]. The solid line in Fig. 2 connects the odd-A abundances and the dashed line connects the total even-A abundances.

From the data presented in Table 1 and in Figs. 1 and 2, the following observations are noted. First, after normalization of the Noddack data to these data, the X-ray spectroscopic data are about ± 30 per cent at variance with the abundances of the present work. Secondly, the abundances of even-atomic-number elements are indeed larger, by roughly a factor of four, than those of the odd-atomic-number elements. Thirdly, the elemental abundance of europium in Richardton (0·080 p.p.m.) as determined in this work agrees well with the abundance of europium in Richardton (0·079 p.p.m.) found by Bate *et al.*[10]. Fourthly, a smooth decrease in abundances is found for both odd A and total even A from $A \approx 137$ to $A \approx 150$. A smooth perturbation in the gradual decline in abundance of both odd A and total even A is noted between $A \approx 150$ and $A \approx 170$, with a peak at $A \approx 163$. This has been explained by Becker and Fowler[11] from considerations of the rapid neutron-capture process in supernovæ and the spheroidal nuclear deformations in the rare-earth region. Fifthly, the meteoritic isotopic ratios of gadolinium-158/gadolinium-160, erbium-168/erbium-170, ytterbium-168/ytterbium-174 and lutetium-175/lutetium-176 agree, within experimental error, with the corresponding terrestrial abundances.

At General Atomic, work is in progress to re-determine the cerium-140/cerium-142 isotopic ratio in chondritic meteorites, and it is planned to ascertain the rare-earth abundances in achondrites and irons. Complete details of this work will be published elsewhere.

We wish to thank Prof. Hans E. Suess, of the University of California, La Jolla, for suggesting this problem and for helpful discussions. Also, we thank Prof. Harold C. Urey, of the University of California, La Jolla, and Prof. John W. Irvine, jun., of the Massachusetts Institute of Technology, for their suggestions. The Allegan meteorite was obtained through the courtesy of Prof. Hans E. Suess; Richardton was obtained through the courtesy of Dr. Brian Mason, of the American Museum of Natural History.

INHIBITION OF THE ANAPHYLACTIC RELEASE OF HISTAMINE FROM CHOPPED GUINEA PIG LUNG BY CHYMOTRYPSIN SUBSTRATES AND INHIBITORS

By DR. K. F. AUSTEN* and DR. W. E. BROCKLEHURST

National Institute for Medical Research, Mill Hill, London, N.W.7

IT has been observed that the anaphylactic release of histamine from sensitized guinea pig lung requires a heat-labile factor[1], which is probably enzymic, and can be inhibited by di*iso*propylfluorophosphate[2]. These findings prompted us to study the effect of peptidase substrates and inhibitors on the anaphylactic release of histamine from sensitized guinea pig lung.

Guinea pigs were sensitized by injection of 10 per cent egg albumin in 0·5 per cent phenol, 1 ml. intraperitoneally and 1 ml. subcutaneously. Approximately three weeks later the lungs were excised and blood was removed by perfusion through the pulmonary artery for 10 min. with Tyrode's solution at 37° C. The lung tissue was chopped into rods 0·4 mm. × 0·4 mm. × 5 mm., washed, and divided into some 24 samples of about 100 mgm. wet weight. These were incubated in Tyrode's solution at 37° C. for 45 min. and then washed twice with Tyrode's solution. Immediately after the second wash each sample of tissue was immersed in 3·0 ml. Tyrode's solution with or without the potential inhibitor and 10 sec. later the antigen, 0·1 mgm. ovalbumin per ml. reaction mixture, was added. After incubation for 15 min. at 37° C. the supernatant fluid was removed from the tissue and kept at 0° C. until it was assayed the same day using the isolated ileum of the guinea pig. Addition of antigen caused the release of 0·3–0·6 μgm. histamine per sample. Any potential inhibitor was always studied in four replicate tubes; three of the samples received antigen and the fourth served as a control for spontaneous release of histamine.

Table 1. COMPOUNDS WHICH FAIL TO INHIBIT THE ANAPHYLACTIC RELEASE OF HISTAMINE FROM CHOPPED, SENSITIZED GUINEA PIG LUNG*

Amino-acids	Esters, amides and hydrazides	Peptides and polypeptides
L-Tryptophan L-Tyrosine** L-Phenylalanine L-Arginine L-Lysine L-Leucine L-Valine L-Glutamic acid L-Cysteine Glycine DL-Alanine DL-Aspartic acid	Benzoyl-L-arginine methyl ester Benzoyl-L-argininamide L-Lysine methyl ester Diacetyl L-lysine ethyl ester† Diacetyl L-lysine hydrazide† L-Glutamic ethyl ester	Glycylglycine DL-Alanylglycine Acetylglycine Acetyl-L-lysine L-Glutathione (reduced) Soy bean trypsin inhibitor‡

* Compounds producing less than 25 per cent inhibition at a concentration of 20 m*M* were termed non-inhibitory.

** Because of water insolubility L-tyrosine could not be tested at greater than 5 m*M*.

† Because of limited supply these compounds could not be tested at greater than 10 m*M*.

‡ Test concentration was 2 mgm./ml. reaction mixture.

In Table 1 are listed the compounds which failed to inhibit histamine release at a concentration of 20 m*M*. The lævorotatory forms of all amino-acids studied were non-inhibitory. The esters and amides of arginine and lysine, which are specific trypsin substrates[3], were not inhibitory, and neither was soy bean trypsin inhibitor at 2 mgm./ml. In addition, γ-glutamylcysteinylglycine (glutathione), and several dipeptides and N-acetyl amino-acids were non-inhibitory.

The compounds which consistently produced more than 50 per cent inhibition of the anaphylactic release of histamine are recorded in Table 2. The first group are esters or amides of L-tyrosine and L-phenylalanine which are typical chymotrypsin substrates[3]. The observation that the esters are better inhibitors than the amide is consistent with the fact that the esters are much more susceptible substrates than the amide[3]. The bifunctional chymotrypsin inhibitors β-phenyl-propionic acid, β-indoleacetic acid and β-(β-indole)propionic acid produced more than 50 per cent inhibition at 2·5 m*M* while the racemic aromatic amino-acids and their dipeptides or N-acetyl derivatives required a concentration of eight times as much to accomplish the same inhibition. Indole, the most potent monofunctional chymotrypsin inhibitor studied by Huang and Niemann[4], was also the most effective inhibitor of histamine release. A concentration of indole of 0·5 m*M* gave more than 50 per cent inhibition whereas virtually total inhibition was obtained with 2·0 m*M*. Di*iso*propylfluorophosphate which is capable of inhibiting chymotrypsin[5], as well as a variety of other esterases, was very effective at 5 m*M*. The finding that di*iso*propylfluorophosphate, which is capable of inhibiting purified chymotrypsin on a 1 : 1 molar basis[6], was not more effective, may be explained by the fact that di*iso*propylfluorophosphate had a relatively short time to inhibit the antigen-activated enzyme and had to do so in the presence of substrate for that enzyme. Histamine release begins within 15 sec. of antigen addition and reaches a maximum rate within 100 sec. Furthermore, the effective concentration of di*iso*propylfluorophosphate may have been significantly diminished by binding to other proteins[7].

In order to ascertain that the inhibitors did not destroy or release antibody, or otherwise impair the ability of the sensitized tissue to respond to antigen, the sensitized tissue was incubated with several of the most potent inhibitors for 15 min. and then thoroughly washed before addition of antigen. The concentration of the inhibitors, L-phenylalanine ethyl ester, phenylacetic acid, indole and di*iso*propylfluorophosphate was selected so as to give more than 80 per cent inhibition. In each instance, after removal of the inhibitor and the addition of antigen, the tissue gave the same histamine release as control tissue treated in a similar fashion with Tyrode's solution. This indicates that the inhibitors are acting exclusively on a reaction activated by the antigen. Furthermore, the failure of di*iso*propylfluorophosphate to inhibit when added and removed before antigen addition implies that the antigen-activated enzyme is present in an inactive precursor form which, like trypsinogen and chymotrypsinogen, is resistant to di*iso*propylfluorophosphate[5].

The failure of trypsin substrates and the soy bean trypsin inhibitor to prevent anaphylactic release of histamine from sensitized guinea pig lung is consistent with the observation that soy bean trypsin inhibitor fails to prevent the antigen-induced histamine release from sensitized rabbit blood[8].

It has been demonstrated that the first component of complement ($C'1$) is capable of exhibiting esterase activity against esters of arginine and tyrosine[9], and is inhibited by di*iso*propylfluorophosphate[9] or sulphydryl-containing compounds like cysteine or reduced glutathione[10]. In our system esters of tyrosine are inhibitory, but esters of arginine or sulphydryl compounds are not; this suggests that $C'1$ is not directly involved. It has also been observed that immune hæmolysis can be inhibited by sulphydryl compounds, esters of arginine and lysine, amides and esters of tyrosine, and peptides with a terminal aromatic amino-acid exhibiting a free carboxyl group[11]. Although sulphydryl compounds and esters of arginine and lysine were not inhibitory in our system, esters of aromatic amino-acids or compounds ending with an aromatic amino-acid with a free carboxyl group were inhibitory. There is thus only partial correspondence between immune hæmolysis and anaphylactic release of histamine. This would be most readily explained by the participation in anaphylaxis of a factor with a substrate specificity similar to that of one of the components of complement.

Table 2. COMPOUNDS WHICH INHIBIT THE ANAPHYLACTIC RELEASE OF HISTAMINE FROM CHOPPED, SENSITIZED GUINEA PIG LUNG

Class of inhibitor	Minimal concentration in m*M* giving greater than 50 per cent inhibition
I. *Chymotrypsin substrates*	
Glycyl-L-tyrosinamide	20
L-Tyrosine ethyl ester	5
N-Acetyl-L-tyrosine ethyl ester	5
L-Phenylalanine ethyl ester	5
II. *Bifunctional chymotrypsin inhibitors*	
DL-Phenylalanine	20
DL-Tryptophan	20
Acetyl-DL-phenylalanine	20
Glycyl-DL-phenylalanine	20
Acetyl-DL-tryptophan	20
Phenylacetic acid	5
β-Phenylpropionic acid	2·5
β-Indoleacetic acid	2·5
β-(β-Indole)propionic acid	2·5
III. *Monofunctional chymotrypsin inhibitors*	
Phenol	1
Skatole	1
Indole	0·5
IV. *Organophosphorus esterase inhibitor*	
Di*iso*propylfluorophosphate	5

The fact that cysteine does not release histamine or enhance antigenic release of histamine suggests that the chymotrypsin-like step is not a simple activation of the intracellular peptidase, cathepsin *C*; furthermore, cathepsin *C* is not inhibited by di*iso*propylfluorophosphate[12]. On the other hand, the chymotrypsin-like activity which is exhibited by suspensions of isolated, intact mast cells from non-sensitized rats is different from cathepsin *C* in that it does not require dipeptide substrates and is inhibited by di*iso*propylfluorophosphate[13]. The participation of such a chymotrypsin-like enzyme in histamine release is compatible with our findings. However, the rat mast cell activity was demonstrated without prior activation by an antigen-antibody reaction. Thus, unless the enzyme was activated during isolation or assay, it follows that the rat mast cells do not contain the inactive precursor form which appears to exist in guinea pig lung tissue.

The observation that the anaphylactic release of histamine from sensitized guinea pig lung is prevented by chymotrypsin substrates and inhibitors but not by trypsin substrates and inhibitors implies that activation of a chymotrypsin-like enzyme is a necessary condition for the anaphylactic release of histamine from guinea pig lung. It does not imply, however, that this alone is a sufficient condition. Indeed, since bifunctional chymotrypsin inhibitors are also effective carboxypeptidase inhibitors, enzymes of the latter group could also play a part in the guinea pig system studied. All our evidence is against a trypsin-like enzyme being involved and, contrary to previous reports[14], trypsin (Armour crystalline trypsin 1,600 μgm./ml. reaction mixture) did not release histamine from the blood-free tissue used in these experiments. Chymotrypsin (Armour crystalline chymotrypsin 1,600 μgm./ml. reaction mixture) also failed to release significant quantities of histamine, but this simply means that extracellular chymotrypsin of pancreatic origin is not an adequate substitute for the antigen-activated chymotrypsin-like enzyme.

HERITABLE CHANGES IN LACTIC STREPTOCOCCI INDUCED BY PHYSICAL TREATMENTS

By B. S. GOSSLING

Research Laboratories of the General Electric Co., Ltd., Wembley, England

LYSIS of cultures of lactic streptococci by bacteriophage was unexpectedly found to be prevented by a violent electrical treatment of the host alone, and this resistance was heritable. In further investigations other physical treatments were similarly effective, and all treatments produced additional heritable changes, two of which were common to the whole surviving population.

The strains of lactic streptococci used were all received by courtesy of Dr. A. A. Nichols of United Dairies, Ltd., and had been selected for early and rapid production of lactic acid from milk. Each responded to a specific phage preparation provided with it.

Six methods of treatment were used, though most of the work was done with the first and sixth to be described.

(1) By strong pulses of ionic current as described in a previous communication[1] and shown in Fig. 1; the lethal effects of this can be ascribed to violent disturbances of the ionic double-layer at the surface of the organism. This was the treatment which first revealed the main effects.

(2) Change of ionic environment[2] following resuspension in phosphate buffer of a deposit centrifuged from Ringer's solution, or vice versa; the resulting sudden disturbance of the double-layer reproduces several of the lethal effects of the more violent ionic currents[1].

(3) Irradiation with germicidal ultra-violet light.

(4) Thermal shock by moderate rapid heating with a rise of 10–15 deg. C. in 5 sec. in a heat-exchanger, repeated 15 or 20 times after intermediate coolings.

(5) Similar repeated heating in 1/50 sec. by 1,500 c./s. alternating current, the small lethal effects of which are not electrical[1].

(6) Heating to a near-lethal temperature reached in 4 min. and thereafter held constant for 5–35 min. according to the strain used and to the severity desired.

In spite of their variety, all these kinds of treatment produced substantially the same effects on all strains tested, provided they were carried to a point where a considerable fraction had lost viability; differences between strains were in degree and not in kind.

Besides suppressing lysis, all the treatments caused other properties of the culture to change, all changes showing continuously progressive development according to the amount or severity of the treatment. Most of the characteristic changes are illustrated in Figs. 1 and 2.

Fig. 1 shows what can be learnt from turbidimetric growth curves[3]. The 'control' curve shows the growth of the untreated culture, and the increasing mortality in the uninfected samples is indicated by the progressive displacements of curves 1–6, curve 6 corresponding to about 10 per cent survival. The 'infected control' curve shows the lysis loss on infection, with a final rise which is the growth of

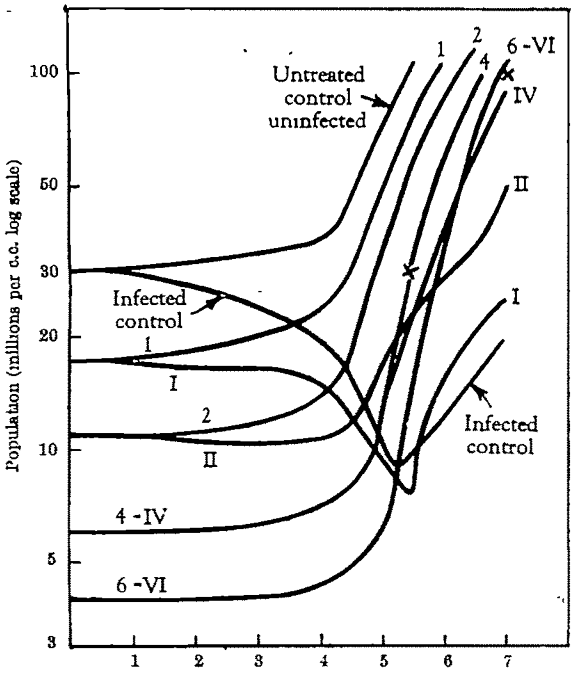

Fig. 1. Turbidimetric growth curves for *Str. lactis* strain M_1S_1 after treatment by pulses of current. Samples taken at six stages of treatment in yeast–dextrose broth with 1·8 μsec. current pulses, 10 per stage, at 53 amp. per sq. cm., 18·5 kV. per cm., that is, power-density 750 kW. per c.c.; temperature rise, 3 deg. C. per stage, annulled by cooling between stages. Control curves from the same culture untreated, curves 1–6 treated but uninfected, curves I–VI infected after treatment, curves 6 and VI are coincident. The points × × exemplify the log-phase growth of the 1/10 dilution of the control; hence curve 6 represents about 10 per cent survival (ref. 2)

A near-lethal heat-treatment gave after 8 min. at 55° C. curves identical with curves 1 and I, and after 25 min. at 55° C. curves identical with curves 6 and VI

the unlysable fraction, 1 in 5,000 by colony counts, of the culture. After the first stage, curve I, there is less lysis, after the second, curve II, scarcely any; but with this strain, though not with some others, growth is delayed by infection and displacements of growth curves are the inverse of those of the uninfected until, after the sixth stage, infection has no effect. This phase of delayed growth does not imply loss of viability, for samples 2–6 give the same colony counts after infection as before. It was the observation of a curve such as VI and later of the coincidence of curves such as 6 and VI that initiated the work.

The growth of the survivors in curve VI, some 10 per cent of the original culture, greatly exceeds the after-growth of the infected control, leaving out of account probable mortality[1] in the treated unlysables, which have been identified as streptococcal. This excess is more clearly shown when survivals and the effects of infection are determined by colony counts; infection which only 0·02 per cent of the control survive has negligible effect on the 10 per cent of the culture which are viable after treatment.

From these quantitative considerations, which are universally applicable to the results of experiments using all the methods of treatment, it is inferred that resistance to lysis has been induced in the entire surviving population and in their descendants, whether during the 7-hr. incubation of Fig. 1 or on the plates. This heritable change has been found to persist during as many as eighty subculturings of one strain, M_1S_1 (Nichols).

Fig. 2, typical of all observed cases, shows by fall of *p*H the progressive changes in acid production from milk inoculated from over-night subcultures from the uninfected samples of Fig. 1: tests by titration or clotting time are concordant. The treatment itself, curves 1–6, causes a progressive slowing of acid production; infection increases this greatly at first, but thereafter less and less until the coincidence of curves 6 and VI shows its effect to have vanished. Later subcultures, again up to 80, have yielded identical curves. One strain susceptible to two phages has had this response to both phages similarly modified by treatment.

The complex process of spontaneous reproduction can apparently be interrupted without the simpler process of acid production being affected, for when tests immediately after treatment are compared with those after subculture, it is always found that mortalities of well over 90 per cent in the first test do not prevent the production of just as much acid as does the restored fully viable population in the subculture. Again, revival of half the non-viables by visible light (after ultra-violet irradiation), or by addition of sodium thioglycollate except after near-lethal heating, produces little or no more acid.

The simultaneous disappearances of the slowing of acid production in all strains, Fig. 2, and of the delay in growth, Fig. 1, of some only, may represent suppression of non-lethal 'reversible' phage-attachments at different sites. Some sites for acid-slowing can be restored by subculture in presence of whey, autolytic products, or even live organisms of the same strain, but not by those from a different strain.

Acid production being a quantitative property, not 'all or nothing' like lysis, the distributions of heritable changes in acid production among the population have been studied by the method of colony isolations.

In Figs. 3*a*, *b* and *c*, typical histograms show no great departures from homogeneity at all stages of a rather gentle heat treatment. Fig. 3*b* represents isolations after a first treatment in bulk of the culture which gave Fig. 3*a*. Further treatments followed, each of a culture from a single average isolation from the preceding. Fig. 3*c* shows the histograms after the third treatment, the majority being then unchanged by infection.

The compact groups of Fig. 3*b* have moved as did the 5-hr. points for a bulk culture in curves 1 and I of Fig. 2, but there are no overlaps with the groups of Fig. 3*a*. This cannot be ascribed to selective elimination of all trace of representatives of the

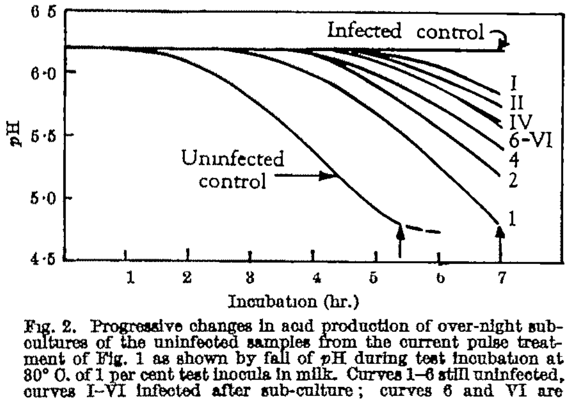

Fig. 2. Progressive changes in acid production of over-night subcultures of the uninfected samples from the current pulse treatment of Fig. 1 as shown by fall of *p*H during test incubation at 30° C. of 1 per cent test inocula in milk. Curves 1–6 still uninfected, curves I–VI infected after sub-culture; curves 6 and VI are coincident. ↑ ↑, clotting points

The near-lethal heat-treatment gave after 8 min. at 55° C. curves identical with curves 1 and I, and after 25 min. at 55° C curves identical with curves 4 and IV

untreated distribution: the mortality was much too small for that.

For the changes in acid production, the inference is again that the entire population, whether infected or uninfected, has experienced continuous changes, the heritability of which is exemplified by the arrows below Fig. 3c after nine subcultures of a single isolation, supported by other cases of continued subculture of isolations from earlier stages of treatment.

The comprehensiveness of the changes is supported by 198 untreated isolations, and by 106 treated, all showing similar compact distributions and displacements after treatment. The original objective of the isolations was to locate individuals the acid production of which was less seriously impaired, but in the event there was little promise of that.

Many of the tests were made using dispersed colonies as the inocula. This was done to avoid any changes of the distributions during subculture. However, when in a number of cases tests were repeated after a subculture, the difference in the results for each isolation was insignificant.

It is common experience that the selected property of rapid production of acid is usually retained only if daily subculturing is not interrupted for more than two days. After freeze-drying it is also lost, but only transitorily, being restored after a few subculturings[3]. In contrast, the modifications induced in the degree of lysis and in acid production by the more drastic physical treatments described here are much more persistent, and are found in all members of the surviving population, perhaps because propagation has been by binary fission[4]. Since other properties besides these are also heritably affected, it would seem that these sensitive strains of lactic streptococci provide a field for the study of induced heritable changes which may prove to be of similar universal incidence.

A detailed account of this work has been prepared for publication.

INCREASE OF SETTLEMENT SIZE AND POPULATION SINCE THE INCEPTION OF AGRICULTURE

By Dr. MAX PETTERSSON
Brunel College of Technology, London, W.3

THE encampments of mesolithic food-gatherers commonly occupied no more than 500 m.^{2}; and the first agricultural settlement was probably about that size. To-day, Greater London occupies more than 10^9 m.^{2}. How has 'maximum size of settlement' varied, during the long period in between? Some relevant data are assembled in Table 1. Most are from the late Prof. V. Gordon Childe. It will be seen that the criteria which he employs lead to estimates which are somewhat on the low side. The logarithms of the area of the largest of these settlements at each period (with asterisk) are plotted in Fig. 1. Hence during the proto-agricultural stage[1], maximum settlement size has, as a first approximation, increased exponentially. Its doubling time is about 600 years; and there seems little doubt that this upsurge is primarily due to the inception and development of food-production, by farming. Since about A.D. 1500, however, in the scientific stage of social evolution[1], maximum settlement area seems (Fig. 1) to have increased still more steeply.

One may, of course, estimate the coefficient of correlation between maximum settlement size and time. For this purpose, the following points were used: Greater London, Greater Rome, Alexandria, Ninevah, Erech, Ur, Naqada, Merimde, Jericho, and a mesolithic camp as at 9000 B.C. A significant coefficient of $+0.96$ was obtained, with $P \ll 0.01$.

The inception of agriculture (*sens. lat.*), in the form of vegeculture[2], may well have been effected by a

Table 1. AREA AND POPULATION OF SETTLEMENTS

Emphasis is on the largest settlements of each period, but a few smaller settlements are included to give perspective. The terms used in columns 8 and 9 are explained in the text

hitherto mesolithic group of only some 25 persons. Agriculture presumably arose in the parallelograms of Figs. 1 and 2; and probably between 8,000 and 10,000 B.C.

The estimates of the populations of ancient settlements are still more tentative than those of their area. Even for modern settlements, regions and countries, we seem to need, for conceptual purposes, some more precise way of expressing the order of magnitude of their populations. Hence let any number between $10^{2\cdot5}$ and $10^{3\cdot5}$ be regarded as a 'power-3' number, and so forth. (Compare *p*H and *pF*.) Then, with regard to their populations, the Vatican State or City and the village of Caerwent in Monmouthshire are both power-3; while London and the Netherlands are both power-7. Over a range of time, there is the notorious difficulty that what is called a city in one age would be called a town, or merely a village, in another. Hence let a 'settlement of power-4-population', such as Third Millenium Ur or Roman London, be regarded as a 'tetrapol', and so forth, as in Table 1. (Gr. *polis*, a city; and compare tetravalent and tetraploid.) 'Power-3' is a much wider category than 'about a thousand'; yet also a precise category. Due to this great width, or 'height', of category, far more than half the entries in columns 8 and 9 of Table 1 will be correct. For the proto-agricultural stage, though not for modern industrial society, column 7 entries can, very roughly, be obtained by subtracting 1·5 from those in column 5. But for the climatic zone containing the Near East[7] it is an improvement to use 1·4, and for the more northerly zone[11] evidently 1·7 or so.

An interesting by-product of this study is an elucidation of the status of Mycenæ, the capital of 'King Agamemnon', and of the Troy of 'King Priam'

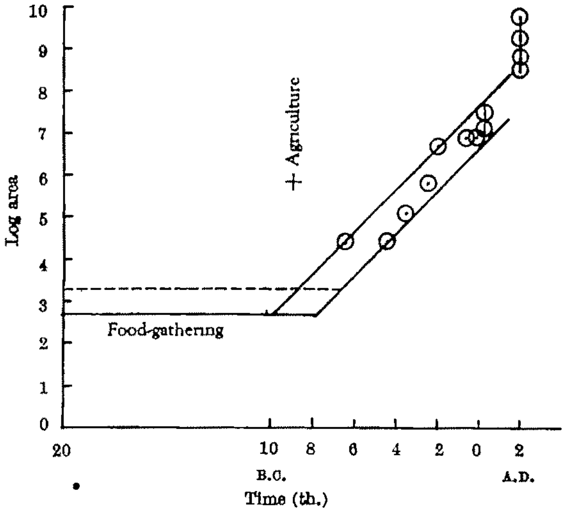

Fig 1. Logarithm of maximum settlement, against time. The levels and points plotted may be identified from Table 1, where they are marked by an asterisk. The two points for Rome have been linked, as also the four points for modern London

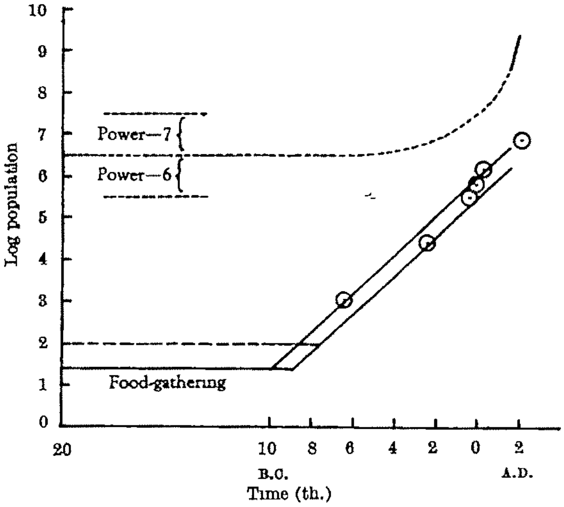

Fig. 2. Logarithm of population, against time. Below, the levels and points plotted refer to maximum settlements, and may be identified from Table 1. Above, the probable course of world population, little known before A.D. 1500

and Homer's "Iliad". Intramural Mycenæ and the famous Troy were—like Caerwent, Aldeburgh and the Vatican City—both tripols.

What is the commonest or modal settlement size at different periods ? Data on England and Wales to-day are provided by the Automobile Association Handbook. Making allowance for conurbations, a sample of 300 settlements was grouped logarithmically according to population, and showed the following distribution of frequencies :

Hexapols		1 per cent
Pentapols		7 ,,
Tetrapols		25 ,,
Tripols		44 ,,
Dipols	? 21	23 ,,
Monopols	? 2	

Thus the modal category is that centred at 10^3 ; and the population of the modal settlement is rather less than the square root of that of the region's largest. But a more exhaustive enumeration of smaller settlements might well take the mode down towards $10^{2.5}$. Hence in England and Wales at A.D. 1500, the modal settlement is likely to have had not more than some $10^{2.5}$ inhabitants. But in mesolithic times, the modal settlement seems likely to have had at least $10^{1.4}$ members[4]. Thus throughout the long proto-agricultural period, the modal settlement population seems to have increased by a factor of only about 10. In contrast, maximum settlements have increased by a factor of about 10^5 (Figs. 1 and 2), and at a far greater rate than total population.

A fairly firm estimate can be deduced for world population in A.D. 1500, being $10^{8.5}$, or about 350 million[14]. A tentative estimate of the population of mesolithic England and Wales is $10^{3.5}$, or about 3,250 (ref. 3, 1). The world population of food-gathering *Homo sapiens* at 10,000 B.C. will, clearly, be between these two limits. The world land area happens to be 10^3 times that of England and Wales. Thus if England and Wales were an averagely populated mesolithic habitat, the pre-agricultural world population would be about $10^{3.5+3} = 10^{6.5}$. On the other hand, if the proto-agricultural increase in total population were by 10^2, or by about the square of increase in modal settlement, the world population at 10,000 B.C. would be $10^{8.5-2}$; and thus also $10^{6.5}$. Hence the population at 10,000 B.C. seems likely to have been somewhere between one million and ten million ; and *Homo sapiens* is almost certain to have been, at that time, either a power-6 or power-7 species (Fig. 2).

The curve of world population in the upper part of Fig. 2 would scarcely be expected to be step-like, due to the relatively slow diffusion of cultural innovations from their centres of origin. For example, South Africa was still mesolithic at the time that Britain was neolithic and when Iraq and Egypt had many tetrapol cities. But the three main stages[1] may be characterized thus :

(1) *Food-gathering.* In the half-million years up to 10,000 B.C., world population may possibly have increased overall by a factor of about 10^2, or less, corresponding to a doubling time of at least 75,000 years.

(2) *Proto-agricultural.* From 10,000 B.C. to A.D. 1500, world population probably increased overall by a factor of about 10^2, corresponding to a doubling time of about 1,730 years ; and during this period, the maximum size of settlement increased by a factor of about 10^5.

(3) *Early part of Scientific stage.* From 1500 to 1950, world population increased overall by a factor of about $10^{0.82}$, corresponding to a doubling time of about 164 years.

With regard to doubling time of population, the greater change is between (1) and (2), rather than (2) and (3).

RADIOASTRONOMY

Roughness of the Moon as a Radar Reflector

THE early work on radar reflexions from the Moon was carried out at metre wave-lengths with long pulses or with continuous wave giving a returned signal which was the total scattering from the lunar surface. Measurements showed that apart from a long-period fading produced by Faraday rotation of the linearly polarized waves in passing through the ionosphere, the reflected signal also had a short-period amplitude modulation produced by lunar libration. If a frequency analysis is carried out on these more rapid fluctuations, the different frequency components can be related to the Doppler frequency from the various regions on the Moon[1], and in this way Evans[2] indicated that most of the radiation was scattered from a central part of the optical disk of a radius only one-third of the lunar radius. More recently, with radars of higher peak power and μsec. pulse-lengths, it has been possible to confirm this result by direct measurement over the wave-length range of at least 10 cm. to 1·5 m. (refs. 3–5).

Senior and Siegel[6] have attempted to explain the radar echo as due mainly to specular reflexions from four or five regions concentrated towards the centre of the Moon which have dimensions comparable to a Fresnel zone and which are smooth to a fraction of a wave-length. To account for the shape of the radar echo each of these regions would have to reflect a signal comparable in amplitude to the signal that would be reflected from a smooth sphere of diameter equal to that of the Moon, and the leading edge of the echo would then remain sensibly constant in amplitude. However, the amplitude of the leading edge of the Moon echo as measured in Malvern with a 5-μsec. pulse-length shows no steady component but fluctuates in a random fashion with period closely related to the Doppler fading; also, a comparison of the signal at the leading edge with that obtained by Yaplee[4] using a 2-μsec. pulse-length shows that the mean amplitude is proportional to the pulse-length and hence to the area of surface illuminated. Further confirmation of the lack of single specular region from the near surface was obtained in a joint experiment with Straiton and Tolbert of the University of Texas[7], who received the pulses transmitted from Malvern after reflexion from the Moon. In this case the mean amplitude of the echo showed a gradual increase reaching a maximum after a time corresponding to a distance of 7·5 km. from the start of the echo. If the lunar surface consists of a large number of small random scatterers such as would be the case of an irregular surface, the expected delay would be about 9 km., in reasonable agreement with the observations, especially as the small difference could be accounted for by the initial rise being lost in the noise-level.

There is thus no evidence that the whole of the echo is due to components from a few large and comparatively smooth regions on the surface of the Moon, but rather that the echo is the result of scattering from a rough surface such that many irregularities contribute. It may be assumed that the surface has vertical irregularities which are greater than a wave-length and a horizontal scale which is considerably larger. If the scale of the irregularities were to increase or their amplitude to decrease, the surface would become smoother and the resulting scattering would tend more towards specular. If the scale were smaller then the scattering would become more isotropic. This latter type of surface would account for the nearly uniform scattering that we see at optical wave-lengths, but in this case it is the microscopic variation in the surface with scales measured in microns or less that predominates. The intermediate case would appear to represent the behaviour of the lunar surface at radio wave-lengths.

To determine the order of magnitude for the roughness, it was decided to measure more accurately the angular scattering properties of the lunar surface at the wave-length of 10 cm., using the 2-MW. radar transmitter in the 45-ft. diameter radio telescope and a pulse-length of 5 μsec. corresponding to a range-resolution of 0·75 km. Since the area of the lunar surface illuminated by the pulse at any one time is constant, the angular scattering law may be obtained by converting the distance travelled by the pulse after first contact with the Moon to angle of incidence at the surface. Because the maximum signal is only a few times greater than the noise-level, a 'range gate' was constructed which enables part of the echo to pass through an integrating stage; the range gate is automatically swept across the echo and the output of the integrator is displayed on a recorder. The duration of the gate was 20 μsec. and with an integration time of 2 sec. it was possible to measure signals which were about 3 per cent of the noise-level.

Thirty-one runs were obtained during the period November 27–December 11, and the mean of these, with corrections for finite width of the gate, shows a very close fit to an exponential law over a range of angles from about 3° to at least 14°. The ratio of the scattered power per unit surface area to the incident power flux, which we define as the effective scattering area per unit surface area, is given by:

$$\sigma = \sigma_0 \exp\{-10\,\theta\}$$

where θ is the angle of incidence and σ_0 is about 0·7.

This law of scattering is consistent with scattering from a rough surface which has irregularities much greater than a wave-length and a horizontal scale equivalent to about twenty times the vertical deviations. We can say that over representative areas of 8,000 km.^{2}, corresponding to the area of the Moon illuminated by a 5-μsec. pulse, the slope would appear to have a random distribution with a root mean square value of about 1 in 20. It is of interest that if we compare the scattering law of the lunar surface with that for the Sea[8] a similar high directivity is observed, but the value of σ_0 is of the order 10 to 100 depending on the state of the Sea. Since the dielectric constant of the Sea is high, and hence the reflectivity of the surface will be close to unity, this would indicate that the reflectivity of the surface of the Moon lies between 10^{-1} and 10^{-2}.

It may be possible to extend these results to the case of radar echoes from planets; but since the planets from which it is most likely that radar echoes can be obtained, Venus, Mars and Jupiter, probably have surfaces of much higher dielectric constant than the Moon, the value of σ_0 at normal incidence is expected to be greater by a factor of 10–100. On the other hand, σ_0 may be modified if the scattering law is appreciably different from that of the Moon, or if there is appreciable absorption due to ionization in the atmosphere of the planet. The total scattering area of the Moon, σ_T, is given by integrating σ over the whole of the surface and we get $\sigma_T = 1{\cdot}4 \times 10^{-2}\pi a^2$, where a is the lunar radius. The total scattering area of a planet would then be approximately equal to the projected area.

ASTROPHYSICS

Solar Terrestrial Relationships

THE proper formulation of a theory of propagation of disturbance from the Sun to Earth must rest upon knowledge of the magnetic field and material density of the intervening space. An interplanetary density, at the Earth's orbit, of order 10^3 protons and electrons per cm.^{3} has been frequently assumed for theoretical purposes. There is now growing evidence that the density is considerably lower than this.

Recently, Sonett *et al.*[1] reported a rocket survey of the distant geomagnetic field carried out on a magnetically quiet day, October 11, 1958. They reported an inverse cube variation of field-strength out to 13·6 Earth radii, suggesting that at most the proton density in interplanetary space is 10^2 per cm.^{3}. However, disturbance recorded in the region 12·3–14·8 Earth radii may be explicable in terms of tangling of the geomagnetic field with an interplanetary magnetic field of order 10^{-4} gauss. In this case the estimate of 10^2 per cm.^{3} could be significantly reduced. Support for this view is found in the work of Block[2], who considers that a solar magnetic field of 10^{-4} gauss may exist in the vicinity of the Earth and that the proton density may be as low as 10^{-1} per cm.^{3}.

Pope[3] recently determined from a study of whistlers an electron density of 80 per cm.^{3} at 4 Earth radii, decreasing steadily to 15 per cm.^{3} at 5·8 Earth radii. This trend indicates lower values farther out. Allcock's[4] distribution of electron density determined from whistler observations extrapolates to 5 electrons per cm.^{3} at 5 Earth radii. Obayashi and Jacobs[5] have inferred from micropulsation studies that the interplanetary density may be of order 1 per cm.^{3}.

Lyman α observations have led Kupperian *et al.*[6] to a determination of between 15 and 45 protons per cm.^{3} in interplanetary space, while Shklovsky[7] derives an upper limit of 200. The latter points out that we cannot be certain whether the scattered Lyman α arises chiefly in the Earth's exosphere or in interplanetary space.

Considerable evidence then exists in favour of much lower proton densities in interplanetary space than was commonly assumed. Should the interplanetary density be as low as 1 proton per cm.^{3} and the resident magnetic field of order 10^{-4} gauss then hydromagnetic waves may be propagated from Sun to Earth all the time. It is just some such constant source of energy which is required to explain the quasi-permanence of magnetic disturbance and auroræ in high latitudes. I have initiated a theory[8,9] of solar terrestrial relationships based upon such a model. Hydromagnetic waves traverse 1 A.U. of such a medium in about a day.

One would expect the Earth to present a large capture cross-section to these waves (perhaps > 10 Earth diameters), for on reaching the vicinity of the Earth where the Earth's field is the same value as the interplanetary field, the waves may be guided down the geomagnetic field lines in the ordinary mode while suffering considerable refraction towards the Earth in the extraordinary mode. Moreover, these waves can cause corpuscular bombardment of the atmosphere[8]. In this way energy may be transmitted from the Sun to the Earth without actual transit of particles. Certainly the Earth may capture enough energy by this means to explain magnetic disturbance and auroræ. Assuming a perturbation magnetic field of a few gammas in interplanetary space, the Alfvén speed 10^8 cm. per sec. and a capture cross-section of 10 Earth diameters, then the rate of delivery of energy to the Earth is 10^{18} ergs per sec. This is adequate to explain intense magnetic disturbance.

I thank Dr. F. Jacka, chief physicist of this Division, for criticism.

Secular and Periodic Motions of the Node of an Artificial Earth-Satellite

IN a recent paper on the effect of the Earth's oblateness on the orbit of a near satellite, King-Hele[1] mars an otherwise commendable presentation by abundant criticism of some earlier papers on this subject by myself and collaborators[2,3]. Although King-Hele's remarks were not so intended, his statements have had the effect of raising serious doubts about the validity of my early solutions and in particular about the usefulness of my approach to the problem of satellite orbit perturbations.

The particular comments by King-Hele that give cause for concern are: "Furthermore, the solution given by Blitzer *et al.* would seem to be incorrect, since a term is omitted in the equations leading up to it. Correct or not, the solution is so lengthy that no progress can be made towards higher-order solutions, and the rotation of the major axis is not obtained".

To set the record straight: (i) The solution referred to is quite correct, as a simple check against the differential equation would show. It so happens that a term in an intermediate step was inadvertently omitted—a mere typographical error. (ii) Concerning the rotation of the major axis, suffice it to say that this had been obtained and the result published[4] almost a year prior to publication of King-Hele's paper, which I now understand was written in 1957. (iii) I am glad to state that the extension of the method to include the higher-order terms proceeds in a direct and straightforward manner. Moreover, the procedure yields detailed information not only regarding the secular motions of the node and perigee but also for the periodic terms, including orbit inclination, major axis and eccentricity.

Due to space limitations only the following expression for the regression of the nodes (those points on the celestial sphere where the satellite crosses the equator) is presented at this time, because of its relevance to determination of the oblateness parameters from satellite observations.

$$\Delta\varphi = \frac{2\pi JR^2\cos i}{a^2(1-e^2)^2}\left\{1 - \frac{JR^2}{24a^2(1-e^2)^2}\left[4(3-20\sin^2 i) - e^2(4 + 5\sin^2 i)\right]\right.$$

$$\left. - \frac{JR^2}{12a^2(1-e^2)^2}\left[16(2-5\sin^2 i)e\cos\omega - (7-15\sin^2 i)e^2\cos 2\omega\right]\right\}$$

$$+ \frac{3\pi DR^4\cos i}{7a^4(1-e^2)^4}\left[(1+\frac{3}{2}e^2)(4-7\sin^2 i) - (3-7\sin^2 i)e^2\cos 2\omega\right]$$

Here $\Delta\varphi$ is the difference in right ascension between two successive ascending nodes, J and D are the coefficients of the second- and fourth-order harmonics in the potential function for the oblate Earth[5], R is the equatorial radius of the Earth, i is the inclination of the orbit to the equator, a and e are the semi-major axis and eccentricity of the osculating ellipse corresponding to the satellite at the node, and ω is the argument of perigee (angular distance from the node to perigee).

Note that: (1) The above expression is valid for arbitrary orbit inclination and eccentricity. (2) The linear term in J contributes only to the secular motion of the node. (3) The quadratic J^2-term contributes a constant (secular) plus two periodic terms; one periodic term has the period of precession of perigee, the other is a smaller term with half the period of perigee motion. (4) The D-term also contributes a constant (secular) term plus a periodic term having half the period of perigee motion. (5) The secular contribution of the D-term is a regression of the nodes for orbit inclinations less than 49·1° ($\sin^2 i = 4/7$); while for $i > 49{\cdot}1°$, the nodes advance. However, this motion is overshadowed by the dominant J-term.

It is of interest to calculate the magnitudes of the secular and periodic terms for satellite 1958β2 (*Vanguard* I). On the basis of the following data[6,7]: $(a/R) = 1{\cdot}3603$; $i = 34{\cdot}26°$; $e = 0{\cdot}1896$; $J = 1{\cdot}6232 \times 10^{-3}$; $D = 0{\cdot}885 = 10^{-5}$; we find the separate contributions of the J and D terms to be:

$$\Delta\varphi \text{ (deg./rev.)} = (0{\cdot}281 - 2{\cdot}79 \times 10^{-4}\cos\omega + 1{\cdot}79 \times 10^{-6}\cos 2\omega)_J + (3{\cdot}58 \times 10^{-4} - 5{\cdot}37 \times 10^{-6}\cos 2\omega)_D.$$

The dominance of the linear (secular) term in J is quite evident.

PROF. BLITZER has, I fear, misinterpreted my comments on his papers. First, I am glad to know that his solution for radial distance was correct. When I found the error in the intermediate equation, it did not seem worth carrying on with checking the analysis, which was extremely lengthy. I made it clear that my doubts about the correctness of the solution were based solely on the error in the intermediate equation. I then went on to say, "the solution is so lengthy that no progress can be made towards higher-order solutions, and the rotation of the major axis is not obtained". Here I was not making a prophecy but only a statement of fact: in the papers I was referring to, there was no progress towards a higher-order solution, and the rotation of the major axis was not obtained. My statement was therefore correct. Next, as is clearly stated on its second page, my paper was "a shortened version of a Ministry of Supply report issued in October 1957", and was written in the summer of 1957. It is therefore scarcely surprising that I made no reference to the paper (his ref. 4) by Prof. Blitzer, which was not published until November 1957.

Finally, Prof. Blitzer may be glad to know that I believe his equation for $\Delta\varphi$ is correct, if osculating elements are used, since it agrees with results obtained by other authors.

PHYSICS

Reduced Temperatures for Nucleation in Supercooled Liquids

THE various methods available for detecting a phase change may depend on spontaneous nucleation-rates which differ greatly in magnitude. Thus although, as nucleation theory shows, critical conditions for the threshold of change may be much the same for methods of widely different sensitivity they are nevertheless quite arbitrary. It therefore seems particularly interesting that critical supercoolings θ for droplets of molten metals and molecular liquids are roughly proportional to the absolute melting temperatures T_f (refs. 1, 2, and 3). Thus where $T_s = T_f - \theta$ is the freezing threshold these results indicate a value of about 0·8 for the reduced tempera-

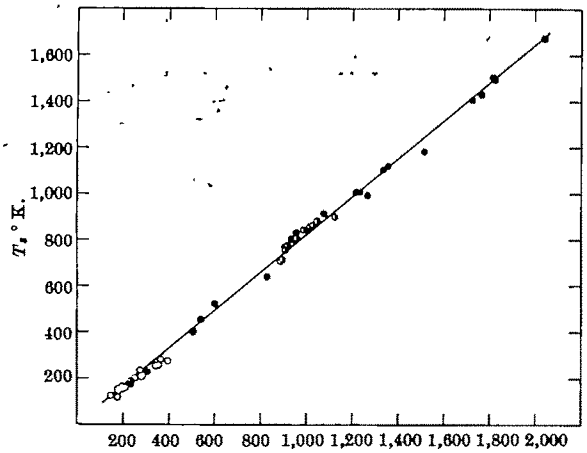

Fig. 1. Threshold of nucleation in supercooled liquids. ○, Molecular compounds (Staveley *et al.*, refs. 2 and 8); ◐, alkali halides (Buckle and Ubbelohde, refs. 4 and 5); ●, metals (Turnbull and Cech, ref. 1, and Turnbull, ref. 8)

ture $\theta = T_s/T_f$. Recent results for alkali halides[4,5] show that for these compounds $\theta \sim 0{\cdot}85$. In all these experiments the observation time was about 10 sec. irrespective of drop size. Collectively the results indicate a value of θ close to 0·82 (Fig. 1).

The parallelism between T_s and T_f, which extends over a very large range of temperature, does not seem to have been previously noted. It suggests some underlying connexion between the irreversible transformation of liquid to solid at the freezing point and the stable co-existence of these phases at the melting point. The value $\theta = 0{\cdot}82$ refers to the quite arbitrary limitations of present methods of observing nucleation. It therefore appears likely that θ will be constant at any given nucleation-rate.

In view of current interest in the problem of liquid structure it seems important to point out that the constancy of θ also shows that the sizes of crystal nuclei, as measured by the number of molecules g^* comprising them, are the same to within an order of magnitude for all the compounds examined. The specific rate of nucleation in supercooled liquids may be written[6]:

$$J = K\exp(-\Delta\Phi^*/kT)\ \text{sec.}^{-1}\ \text{cm.}^{-3}$$

where $\Delta\Phi^*$ is the free energy of nucleation and K is a factor which is relatively insensitive to temperature for liquids which do not form glasses. By specifying the rate J the values of both θ and $\Delta\Phi^*/kT$ are determined for any such liquid. For the nucleation threshold, therefore:

$$\Delta\Phi^*/kT_s = \ln(K/J_s) = c_s \text{ (a constant)};$$
$$\Delta\Phi^* = c_s\theta kT_f$$

Assuming that a crystal nucleus is adequately described by a simple model of the Volmer type[7]:

$$g^* = 2\Delta\Phi^*/\Delta\psi$$

where $\Delta\psi$ is the decrease of free energy per bulk molecule. By means of the relation[4]:

$$N\Delta\psi = \theta\Delta S_f$$

where ΔS_f is the molar entropy of fusion, the following expression is obtained for the number of molecules in the threshold nucleus:

$$g_s^* = 2c_sR\theta/[(1-\theta)\Delta S_f]$$

As c_s is roughly 60 (refs. 2, 4 and 8) a rule of thumb is:

$$g_s^* \sim 1{,}000/\Delta S_f$$

Metallic nuclei contain 200–400 atoms, while for molecular compounds g_s^* is mostly less than 200. Previous estimates of g_s^* for alkali halides[4] were based on inadequate fusion data. Recent determinations[9] of entropies of fusion show that the nuclei contain about 300 ions.

Self-Quenching Geiger Counters containing Mixtures of Permanent Gases

In a recent communication, Collinson, Demetsopoullos, Dennis and Zarzycki[1] refer to a paper of mine[2] as negating the earlier work of Shore[3].

My paper, it is true, reports the failure of a mixture composed according to Shore's prescription, but it also states that xenon–oxygen fillings worked very well if a low oxygen content was chosen. Besides that, the paper says that no harm was done even by a continuous discharge, running for 1 hr. at 50 μamp. The startling quenching mechanism was explained by me as due to a certain resonance phenomenon, which had been found by the spectroscopists[4] and which occurs at very low oxygen contents only.

Perhaps the addition of nitrogen or argon results in a still unknown, but no less effectual mechanism, even at higher oxygen contents. Only by 'burning out' in a continuous discharge, however, can it be certain that no unintentional admixture of other gases or vapours provokes self-quenching behaviour in apparently pure permanent gases, as discovered by Bosch[5].

Oswald Riedel

[5] Bosch, C., *Ann. Physik*, 19, 65 (1934).

We feel that the xenon–oxygen phenomenon referred to by Dr. Riedel, although interesting, is only of importance in mixtures where xenon is the main gas. While such an effect is possibly a small contributory factor in the quenching mechanism of the argon–xenon–oxygen–nitrogen mixtures which we have investigated, our results show that the important mechanism is the interaction of xenon with argon metastable states.

It is most unlikely that the behaviour of these mixtures could be accounted for, as Dr. Riedel suggests, by the unintentional introduction of some other gas or vapour. This was shown by the constancy of the starting voltages of the counter even after many hours of continuous discharge. One counter in particular was run steadily for two months, recording 10^9 counts and operated in continuous discharge for about 30 min. each day. At the end of this period the starting voltage was unaltered, although the plateau length was increased.

We consider that Dr. Riedel's lack of success in obtaining Geiger counting regions with the Shore mixture can be attributed to the choice of cathode, namely, aluminium, and to the use of hard rubber in the construction of the counter, which precluded the possibility of baking, etc., during evacuation.

MINERALOGY

A Regular Mixed-Layer Chlorite–Vermiculite Mineral

Various mixed-layer clay minerals have been reported in many publications. So far as the structure is concerned, the main interest in this field of investigations has been in examining the way of stacking in the direction along the perpendicular to the layer, and the order–disorder problem involved in these minerals has only been discussed in terms of the variations of X-ray basal reflexions.

The present work has been undertaken for a regular mixed-layer chlorite–vermiculite mineral with two main objectives in view: (1) to examine the change in basal reflexions in the course of dehydration; (2) to clarify the regularity of stacking parallel to the layer, which is shown by the presence of reflexions other than the (00*l*)'s.

A regular mixed-layer mineral was found in the alteration zone of mudstone belonging to a tertiary bed in Noto Peninsula, Japan, and its pure specimen was obtained by elutriating the crude clay. In view of the complexity of X-ray diffraction pattern of the mineral, two different specimens were provided for its X-ray examinations. The basal reflexions of the mineral were examined without ambiguity by using a completely oriented specimen which was obtained by the sedimentation method. The 29·2 Å. reflexion and the presence of the rational sequence of its higher-order reflexions indicate that the mineral is of regular mixed-layer type. A randomly oriented specimen yielded diffraction peaks corresponding to the (020), (20*l*), (13*l*) and (060) reflexions. The chemical composition, differential thermal analysis curve and *d*-spacing of the (060)—1·53 Å.—strongly suggest that the mineral is made up of the chlorite and vermiculite layers rather than the chlorite–montmorillonite.

By means of an X-ray diffractometer with a heating furnace, measurements were made of the changes in the diffraction lines when the specimens were subjected to heat treatment. As has been described by Walker[1], the dehydration process of vermiculite is somewhat complicated. It proceeds from the 14·8 Å. phase (fully hydrated), through the 13·6 Å. and 11·6 Å. phases, finally to the 9·1 Å. phase. Therefore, one may predict that heating of this mineral at 300° C. might result in the formation of a random mixed-layer lattice with the components of 26 Å. (14·4 + 11·6) and 23·5 Å. (14·4 + 9·1) layers. Of this mineral, however, a striking feature is that this is not the case. The close examination of the line profiles at 6–8° and 10–13° in 2θ with copper *Kα* radiation shows that there is a tendency for crystallites to segregate into two parts, namely, the 26 Å. and 23·5 Å. phases respectively. Further heating to 500° C. brings about a monophase again with the layer thickness of about 24 Å.

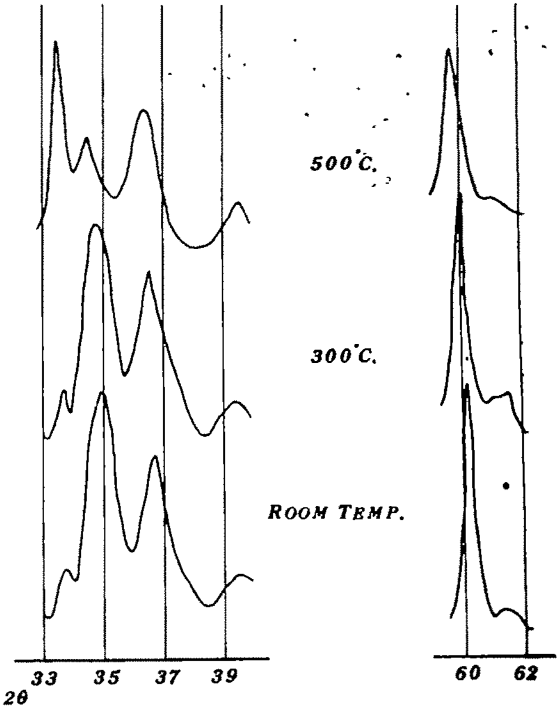

Fig. 1. Diffractometer traces at various temperatures

The evidence for a three-dimensional order in this mineral rests largely on the presence of diffraction peaks ranging from 30° to 40°. These reflexions are not observed in the diffraction pattern of the oriented specimen and are tentatively indexed as (20*l*) and (13*l*). The changes which occurred in the position and intensity of these reflexions on heating are shown in Fig. 1 together with the (060) reflexion. An expansion of the *b*-periodicity upon heating can be seen. It is not certain whether the expansion is merely due to the thermal vibration of atoms or to some structural change within the layer. Judging by the change in intensities of the (20*l*) and (13*l*) reflexions, however, we are inclined to think that the migration of atoms and the decrease in the degree of distortion of the silica-layer on heating would give rise to the lattice expansion of the layer.

The shrinkage in the *c*-periodicity would move the positions of the (20*l*) and (13*l*) reflexions toward the higher-angle side, whereas the expansion of the layer would result in the displacement of these reflexions toward the lower-angle side. In view of the small number of reflexions, little can be said concerning the indices of these reflexions or of the detailed structure of the mineral.

A detailed description of this work will be given in the near future.

RADIATION CHEMISTRY

Use of Nitrous Oxide to discriminate between the Forms of Hydrogen Atoms ($H^{\bullet}$ and H_2^+ ?) produced by γ-Irradiation of Aqueous Solutions

IN 1958 Proskurnin and Chernova[1] reported that $G(Fe^{3+})$ for oxygen-free solutions of ferrous sulphate saturated with nitrous oxide in 0·8 N sulphuric acid irradiated with cobalt-60 γ-rays has a value of between 12 and 13 which depends on the concentration of ferrous ion. This is larger than the value of 8·2 obtained for completely degassed solutions[2,3] and Proskurnin and Chernova suggested that the difference might be due to the occurrence of reactions (1) and (2):

$$NNO + H \rightarrow NNOH \quad (1)$$

$$NNOH + Fe^{2+} \rightarrow N_2 + OH^- + Fe^{3+} \quad (2)$$

However, since every hydrogen atom generated in a completely degassed solution of ferrous sulphate in 0·8 N sulphuric acid always oxidizes a ferrous ion according to reaction (3a) or (3b) or to the reaction sequence (3c):

$$H + Fe^{2+} . H_2O \rightarrow H_2 + Fe^{3+} + CH^- \quad (3a)$$

$$H + H^+ + Fe^{2+} \rightarrow H_2 + Fe^{3+} \quad (3b)$$

$$H + H^+ \rightarrow H_2^+ ;\ H_2^+ + Fe^{2+} \rightarrow H_2 + Fe^{3+} \quad (3c)$$

it is not clear why the presence of nitrous oxide should have any effect on $G(Fe^{3+})$.

In order to clarify the situation and because reaction (1) may in fact be (4):

$$N_2O + H \rightarrow N_2 + OH \quad (4)$$

and thus provide a much-needed ready means of converting hydrogen atoms into hydroxyl radicals, we have undertaken a more detailed investigation of the radiation chemistry of aqueous solutions containing nitrous oxide. Some of the results for ferrous sulphate solutions are shown in Table 1, from which it is evident that: (a) $G(Fe^{3+})$ has the same value in the deaerated nitrous oxide-containing solution as in a nitrous oxide-free solution; (b) the total gas yield is the same in both systems and equal to $G_{H_2} + G_H$; (c) in the nitrous oxide-containing system some nitrogen is always produced and the ratio $G(N_2)/G(H_2)$ increases slightly as the pH is increased to 2 and then rises sharply with further increase of pH.

Table 1. γ-RAY YIELDS IN OXYGEN-FREE, NITROUS OXIDE-CONTAINING ACIDIFIED mM FERROUS SULPHATE SOLUTION

Dose-rate = 1·05 × 10^{18} eV. ml.$^{-1}$ min.$^{-1}$

3·30	,,	0·57	2·61	3·18	6·2

* 0·8 N sulphuric acid solution.

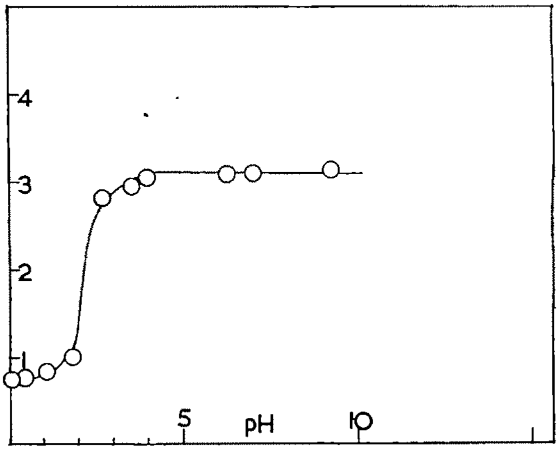

Fig. 1. $G(N_2)$ as a function of pH for cobalt-60 γ-irradiated solutions of nitrous oxide in pure water at room temperature. P_{N_2O} = 395 mm. mercury; dose-rate = 1·05 × 10^{18} eV. ml.$^{-1}$ min.$^{-1}$; pH varied by addition of sulphuric acid or sodium hydroxide

Result (a) indicates that reaction (5) does not occur, a conclusion which we have verified by a study of the effect of N_2O on the stoichiometry of the Fenton reaction:

$$HO + N_2O \rightarrow HO_2 + N_2 \quad (5)$$

All the results require that a large fraction, but by no means all, of those species which in acid solution oxidize ferrous ion according to (3) are incapable of reacting with nitrous oxide at $p\mathrm{H} < 2$, but become able to do so according to reaction (1) or (4) at $p\mathrm{H} >$ 2·3. To test this hypothesis we have measured $G(H_2)$, $G(N_2)$, $G(O_2)$ and $G(H_2O_2)$ for solutions of nitrous oxide in pure water over a wide range of pH. The variation of $G(N_2)$ with pH is shown in Fig. 1.

The value of $G(N_2)$ at $p\mathrm{H} > 2·7$ is that expected on the hypothesis that all the available hydrogen atoms or their stoichiometrical equivalents are scavenged by nitrous oxide in a reaction in which 1 mole of nitrogen appears for every mole of hydrogen atoms so scavenged, for example, by reaction (4). Below this pH, $G(N_2)$ falls sharply because a large proportion of these species reacts with acid and is thereby rendered incapable of reducing nitrous oxide. We consider this fraction to consist of hydrogen atoms which in their protonated form (H_2^+) are incapable of reacting with nitrous oxide and for which $pK_a(H_2^+) \simeq$ 2·3.

The fact that $G(N_2)$ does not become zero in solutions containing nitrous oxide at $p\mathrm{H} < 2$ is especially significant, and we interpret this as evidence for the possible existence of two different species of H atom or H atom precursor, only one of which is capable of reducing nitrous oxide in this low pH range. At present we are unable to say whether the form reactive to nitrous oxide is a solvated electron ($e^-_{aq.}$) or some other entity such as an excited water molecule. The existence of more than one form of hydrogen atom has been postulated by several groups of workers, but nitrous oxide affords perhaps the clearest evidence for this and the related ionic equilibria. A more detailed account of this and related work will be published elsewhere.

Use of Nitrous Oxide to discriminate between Various Forms of Hydrogen Atoms existing in Aqueous Solutions of Potassium Iodide irradiated with Ultra-violet Light

Deaerated, acidified, aqueous solutions of potassium iodide decompose to form equimolar amounts of hydrogen and iodine under the influence of light of wave-length less than 2600 Å. which is absorbed by the hydrated iodide ion ($I^-_{aq.}$). The quantum yield is small, but increases with increasing iodide and hydrion concentration. A postulated cause[1] of the effect of *p*H on the quantum yield is that hydrogen atoms found in the primary act can be protonated to form the hydrogen molecule ion, H_2^+, which will oxidize iodide ions in the reaction (1), whereas hydrogen atoms serve only to reduce iodine atoms and molecules. In the preceding communication[2] it was shown that nitrous oxide is inert to H_2^+, but reacts rapidly with hydrogen atoms most probably according to equation (3), and that $pK_a(H_2^+) \simeq 2{\cdot}3$:

$$H_2^+ + I^- \rightarrow H_2 + I \qquad (1)$$

$$H + I \rightarrow HI \qquad (2a)$$

$$H + I_2 \rightarrow HI + I \qquad (2b)$$

$$H + N_2O \rightarrow N_2 + OH \qquad (3)$$

Therefore, if solutions of potassium iodide saturated with nitrous oxide are irradiated with ultra-violet light it would be expected that little or no nitrogen would be produced until the *p*H of the solution exceeded 2, when reaction (3) becomes possible and $\varphi(N_2)$ should increase steeply to a limiting value which would be the true primary quantum yield of the iodide photolysis. The hydroxyl radicals liberated in reaction (3) will oxidize iodide ions very rapidly according to equation (4):

$$OH + I^- \rightarrow OH^- + I \qquad (4)$$

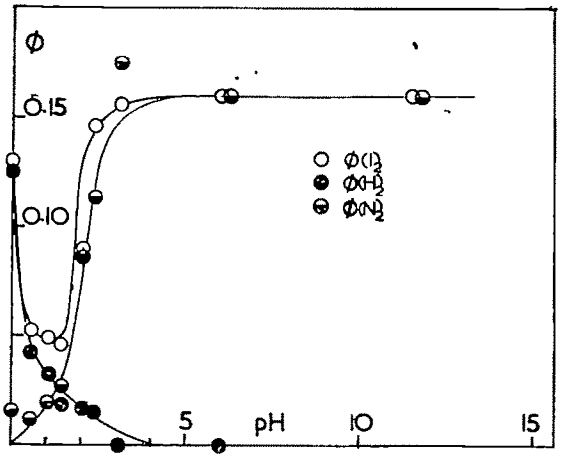

Fig. 1. $\varphi(H_2)$, $\varphi(I_2)$ and $\varphi(N_2)$ of aqueous solutions of potassium iodide containing nitrous oxide. [KI] = 0·276 *M*; P_{N_2O} = 810 mm. mercury; incident light intensity = 7 5 × 10^{14} quanta cm.$^{-2}$ sec.$^{-1}$ in wave-length range 2000–2600 Å. *p*H varied by addition of sulphuric acid or potassium hydroxide

We have recently measured the quantum yields of formation of hydrogen, nitrogen and iodine for this system over a wide range of *p*H, and the results, which are shown in Fig. 1, entirely confirm these predictions. It will be noticed that $\varphi(N_2)$ remains constant at 0·16 over the *p*H range 3–11 and therefore whatever forms hydrogen atoms assume in strong alkali, for example, $e^-_{aq.}$ or H_2O^-, also react rapidly with nitrous oxide in a reaction which is stoichiometrically equivalent to reaction (3).

As the *p*H is decreased below 3, $\varphi(N_2)$ diminishes rapidly and ultimately becomes zero, whereas $\varphi(H_2)$ increases steadily to a value which in $\sim 2\ N$ sulphuric acid approaches the primary quantum yield, and $\varphi(I_2)$ passes through a minimum value but is always equal to $\varphi(H_2) + \varphi(N_2)$. These and related results, in particular the observation that, contrary to the predictions of the Rigg and Weiss mechanism, $\varphi(H_2)$ and $\varphi(I_2)$ for deaerated iodide solutions are independent of the light intensity, have led us to the view that the mechanism of the photolysis of deaerated iodide solutions more nearly approaches the following than any of those hitherto published[1]:

$$I^-_{aq.} \xrightarrow{h\nu} I^-_{aq.}{}^* \text{ (electronically excited aquated iodide ion)} \qquad (4)$$

$$I^-_{aq.}{}^* \rightarrow I^-_{aq.} \text{ (degradation)} \qquad (5)$$

$$I^-_{aq.}{}^* + I^- \rightarrow I_2^- + OH^- + H \qquad (6)$$

$$H + H^+ \rightarrow H_2^+ \qquad (7)$$

$$H_2^+ \rightarrow H + H^+ \qquad (8)$$

$$H_2^+ + I_2^- \rightarrow H_2 + I_2 \qquad (9)$$

$$H + I_2^- \rightarrow H^+ + 2I^- \qquad (10)$$

Further details of these and related experiments will be published elsewhere. One of us (S. A. S.) is indebted to the Distillers Co. for financial help.

CHEMISTRY

A Reversible Nitrate Electrode

Following some earlier work in this Laboratory, a number of electrodes have been constructed which are capable of displaying a more or less reproducible nitrate function. The electrodes are of interest in that they make possible the determination of nitrates by potentiometric methods.

To make the electrodes, a slightly lumpy (½–1 mm.) sample of powdered zinc fluoride was made up to a viscous paste with 'Diakon' plastic (Imperial Chemical Industries, Ltd.) in chloroform, and coated on to a zinc rod (5 mm. diam.), such that several fragments of the salt were in contact both with the zinc core and with the surrounding solution. The electrodes were 'aged' by standing in 0·4 *M* calcium nitrate solution for 1–7 days.

The gelatinous coating of a basic zinc salt produced on the hydrolysis of the fluoride is apparently able to

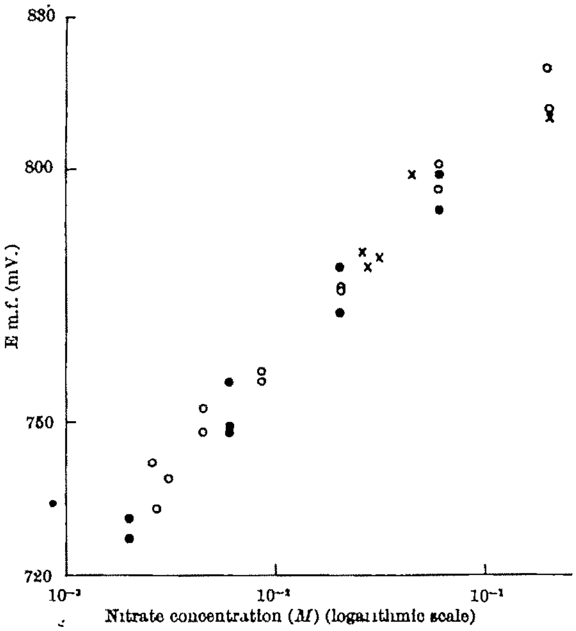

Fig. 1. Electrode potentials, relative to saturated calomel standard, in solutions of calcium and potassium nitrates ●, Calcium nitrate (four series); ○, calcium nitrate + 0 0025 *M* potassium nitrate (two series); ×, calcium nitrate + 0·025 *M* potassium nitrate (one series)

display an electrode function for the anion of the solution in which the electrode has been aged. Fig. 1 shows the electrode potentials in solutions of calcium and potassium nitrate, relative to saturated calomel, of such an electrode after it had been aged for 12 hr. in 0·4 *M* calcium nitrate solution. This particular electrode has been aged first in 0·1 *M* calcium chloride solution, following which it showed a reversible chloride function. Chloride ageing is not necessary for an electrode to show a nitrate function. Stable potentials were achieved after 15 min. provided that the air/solution interface on the electrode surface was protected by a coating of impermeable plastic. No electrode function was shown in nitrate solutions of concentrations less than 0·001 *M*.

This work was carried out during the tenure of an Agricultural Research Council Postgraduate Studentship.

Heats and Entropies of Reaction of Transition Metal Ions with Ethylenediamine

The heats of formation of complexes between ligands and metal ions are very important to further the ligand field-theory and check its implications. Until now, only the heats of hydration of the first transition group ions have been used for this purpose[1] as the thermochemical data on the complexes formed by ligands other than water are very incomplete. The transition metal complexes of ethylenediamine, which have a very nearly octahedral configuration, could also be fruitfully studied in terms of ligand field-theory. Unfortunately only the thermal data on nickel (II), copper (II) and zinc (II) complexes are known[2], and so the formation constants have been used instead of the values of enthalpy changes, with the optimistic assumption that the entropy changes remain constant[1,3].

For this reason we have measured calorimetrically under similar conditions the heats of the stepwise formation of the ethylenediamine complexes of manganese (II), iron (II), cobalt (II), which are easily oxidized, as well as of nickel (II) and zinc (II). Copper was not taken into consideration since, because of the Jahn–Teller effect, the ligand field stabilization energy is difficult to estimate. Moreover, the third molecule of ethylenediamine is probably bound to the metal through only one nitrogen atom[4].

The calorimetric measurements were carried out using a calorimeter similar to that described by Davies, Singer and Staveley[2a]. The systems investigated were $2 \cdot 5 \times 10^{-2}$ *M* in metal sulphate and 1 *M* in potassium chloride. In the case of manganese, iron and cobalt, oxidation was prevented by bubbling nitrogen slowly through the calorimetric liquid during the measurements. The actual ionic composition of the solution was calculated from a knowledge of the stability constants[5]. The values of ΔH_1, ΔH_{1-2} and ΔH_{1-3} were obtained by combining the results of the measurements made at three different $\bar{n}$ values. For the measurements at low $\bar{n}$ values, the solutions were buffered with hydrochloric acid in order to prevent the precipitation of basic salts. Experimental conditions made it necessary for us to correct the heats of reaction for the side reactions:

$$2\,\mathrm{enH^+} \rightleftharpoons \mathrm{en} + \mathrm{enH_2^{++}} \quad \text{and}$$
$$\mathrm{en} + \mathrm{H_2O} \rightleftharpoons \mathrm{enH^+} + \mathrm{OH^-}$$

The heats of reaction have been combined with the known free-energy changes to obtain the entropy changes.

Table 1 gives the values of ΔH, ΔF and ΔS at 25° for the formation of mono-, di- and *tris*-ethylenediamine complexes. The values of ΔH_1, ΔH_{1-2} and ΔH_{1-3} are roughly in the ratio 1 : 2 : 3, that is, $\Delta H_1 \approx \Delta H_2 \approx \Delta H_3$. This confirms Poulsen and Bjerrum's statement[2b] that such a ratio is to be

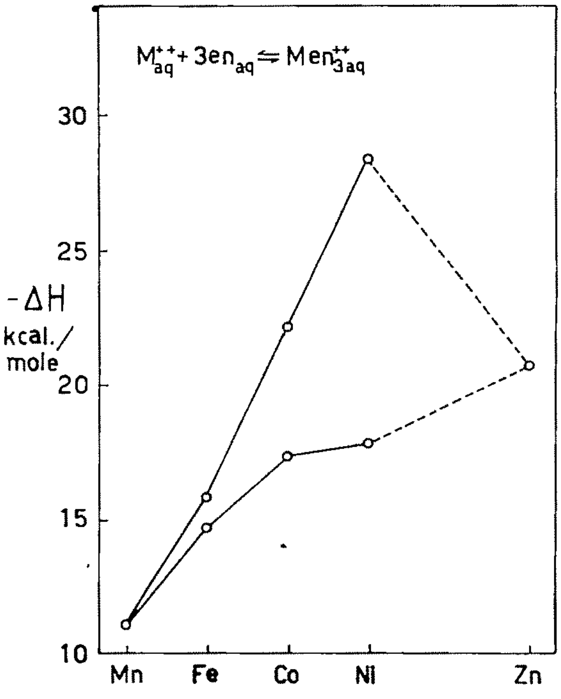

Fig. 1. Heats of formation of metal(II).3en complexes plotted against atomic number

Table 1. THERMODYNAMIC FUNCTIONS FOR SOME METAL(II)-ETHYLENEDIAMINE SYSTEMS IN 1 M POTASSIUM CHLORIDE AT 25°

	Mn^{++}	Fe^{++}	Co^{++}	Ni^{++}	Zn^{++}
$-\Delta H_1$	2·80	5·05	6 90	8·90	6·65
$-\Delta H_{1-2}$	6 00	10 40	13·95	18·35	13 75
$-\Delta H_{1-3}$ (kcal./mole)	11 05	15·85	22·15	28·35	20 70
$-\Delta F_1$	3·75	5·90	8·10	10·50	7·90
$-\Delta F_{1-2}$	6 65	10·45	14 55	19 20	14·40
$-\Delta F_{1-3}$ (kcal./mole)	7 90	13·25	18·65	25·10	16·80
ΔS_1	+3·2	+2 9	+4·0	+5·4	+4·2
ΔS_{1-2}	+2·2	+0 2	+2·0	+2 9	+2·2
ΔS_{1-3} (e.u.)	−10·5	−8 7	−11 8	−10·9	−13·1

expected for all normal complexes, that is, complexes free from steric strains and which undergo no change in multiplicity during stepwise complex formation. Only in the case of manganese is the ΔH_2 value very much higher than either ΔH_1 or ΔH_3. In Fig. 1 the experimental ΔH_{1-3} values (upper line) as well as the corrected values for the ligand-field stabilization energy (lower line) are plotted against the atomic number of the metal. The $\Delta H_{1-3\text{ cryst.}}$ corrections were calculated according to the formula:

$$\Delta H_{1-3\text{ cryst.}} = (4n_{\epsilon} - 6n_{y})\,(Dq_{6\,\text{H}_2\text{O}} - Dq_{3\,\text{en}})$$

The corrected values all lie above the straight line joining manganese to zinc. Therefore the hypothesis according to which the corrected values for the ligand-field stabilization energy vary linearly with atomic number[1] is not verified in this case.

A more detailed account of this work will be published elsewhere.

Molecular Quadrupole Moment of Nitric Oxide

IT is known that nitric oxide is an interesting case of a three-electron bond. Taking the x-axis along the line of centres, the isolated atoms may be described as:

$$\text{N}\ (1s)^2\,(2s)^2\,(2p_x)\,(2p_y)\,(2p_z)$$
$$\text{O}\ (1s)^2\,(2s)^2\,(2p_x)\,(2p_y)\,(2p_z)^2$$

The molecular orbital description of the molecule is then[1]:

$$\text{NO}\ KK(2s_N)^2\,(2s_O)^2\,(\sigma 2p_x)^2\,(\pi 2p_y)^2\,(\pi 2p_z)^2\,(\pi^* 2p_z)$$

The two electrons in the MO $(\sigma 2p_x)$ form a σ bond, the four in $(\pi 2p_y)$, $(\pi 2p_z)$—degenerate orbitals—form π bonds, whereas the remaining single electron in $(\pi^* 2p_z)$ is antibonding.

The quadrupole moment $Q_{\overline{\text{mol.}}}$ due to the charge distribution of the nuclei and electrons may be defined[2] as:

$$Q_{\text{mol.}} = \tfrac{1}{2}\iiint \nu_i \rho_i 2(3\cos^2\theta_i - 1)\,d\tau \qquad (1)$$

where ν_i is an element of charge (electron or nucleus), ρ_i is the distance of the charge from the mass centre and θ_i is the angle between the internuclear axis and ρ_i. $Q_{\text{mol.}}$ may be treated as a sum of contributions due to the charge distribution of the nuclei N, O ($= Q_n$) and the electrons ($= Q_e$).

The following assumptions are made in the calculations: (1) The mass centre of the system is located at the midpoint of the internuclear line nitric oxide. (2) The bond N—O is of a pure covalent type with no hybridization on N or O atoms. (3) The molecular orbitals are represented by combinations of Slater type atomic orbitals with suitable screening constants for N and O. The contribution of the slight non-orthogonality of the molecular orbitals is negligible[3]. (4) The exchange quadrupole contributions are negligible[3].

Since the four electrons in spherical s shells cancel four units of the nuclear contribution in both N and O, we have:

$$Q_n = 3e\left(\frac{R}{2}\right)^2 + 4e\left(\frac{R}{2}\right)^2 \qquad (2)$$

R being the internuclear distance and e the protonic charge. For evaluating the electronic contribution we may use the equation:

$$Q_e = -\frac{e}{2}\,\Sigma_{MO} < \psi_{MO}\rho_e{}^2\,(3\cos^2\theta_e - 1)\psi^*{}_{MO} > \qquad (3)$$

The calculations are essentially similar to those of Greenhow and Smith[3]. The necessary overlap integrals are read from Mulliken's[4] master tables. The quadrupole integrals of the form:

$$Q(2p_\sigma) = -\frac{e}{2}\int \psi_A(2p_\sigma)x\ \rho_e{}^2(3\cos^2\theta_e - 1)\ \psi_A(2p_\sigma)d\tau$$

are read from Greenhow and Smith[3] as they were conveniently tabulated in units of eR^2.

The final value of $Q_{\text{mol.}}$ comes out as $+\,1{\cdot}57\ ea_H{}^2$ as against the experimental value[5] of $0{\cdot}28 \times 10^{-16}$ E.S.U. or $1{\cdot}01\ ea_H{}^2$, from observation of microwave collision diameters. It may, however, be mentioned that the sign of Q is not given by experiment, and the magnitude may be in error by as much as 50 per cent as a result of some theoretical approximations in deriving Q from microwave line-widths.

It is rather simple to calculate the nuclear contribution Q_n with reference to the exact mass centre of the molecule, which is located at a distance of 8/15 R from the N atom. In this case $Q_{\text{mol.}}$ turns out to be $1{\cdot}45\ ea_H{}^2$. The error introduced in Q_n due to the approximation (1) is estimated as only ~ 1 per cent though it is ~ 8 per cent in the over-all moment. But in evaluating Q_e this makes the integrals complicated.

Concentration-Dependent Sedimentation of Aggregating Proteins in the Ultracentrifuge

PROTEINS are by nature sticky substances, and it is not surprising that many of them form molecular aggregates in solution at well below the concentration needed for the appearance of a stable solid phase. Ultracentrifuge measurements provide a direct method of detecting and estimating such aggregation, and this communication is concerned with the interpretation of these measurements when aggregation is rapidly reversible, and the velocity of each sedimenting species is a function of the total concentration of protein.

The detailed experiments of Schwert[1] with α-chymotrypsin illustrate one of the most noticeable effects of strong aggregation on sedimentation. The sedimentation velocity of α-chymotrypsin was shown to increase sharply with concentration at low concentrations of protein, to reach a maximum value, and then to decrease steadily with further increase of concentration[1]. The effect was sensitive to changes in *p*H and ionic strength.

As is now well understood, this behaviour is due to the opposition of two factors: the increase in relative sedimentation velocity of the protein as a whole, as the average particle size increases with concentration, and the normal decrease in velocity caused by changes in the viscosity and density of the solution and in the back-flow of solvent[2,3]. This can be expressed theoretically by two methods. The first, suggested by Tiselius[4] (see also ref. 2, and Goldberg[5]), calculates the velocity of the boundary as if this remained sharp, and gives the weight-average velocity of the protein molecules. The second method[6,7] takes account of the spreading of the boundary by differential transport, although making no allowance for spreading by diffusion, and calculates the velocity of the median of the boundary.

These two methods are illustrated by curves in Fig. 1, calculated for the simplest case of aggregation, reversible dimerization. It will be found that they resemble closely the types of curve obtained by Schwert in the reference quoted above. More general cases will be considered in a later paper. In the present case, the equilibrium between monomer and dimer has been assumed to be governed by the equation $a_2 = ka^2$, where k is a constant, and a and a_2 are the respective molecular concentrations of monomer and dimer. The velocities of the species have been regarded as decreasing linearly with concentration, as for non-aggregating proteins[8].

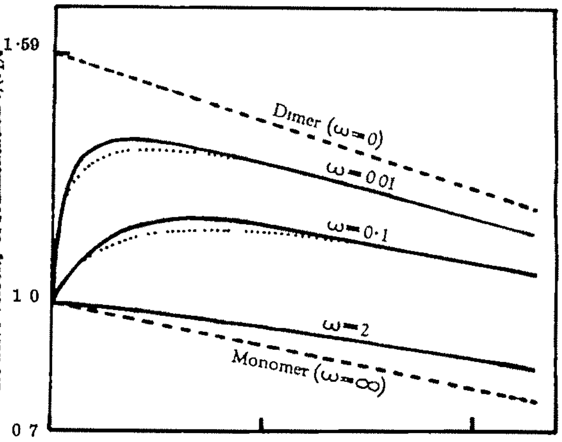

Fig. 1. Velocity of sedimentation in the ultracentrifuge as a function of concentration for monomer–dimer systems in reversible equilibrium. .. .. .., Weight–average velocity; ———, velocity of median of boundary; ----, limiting velocities

Thus:

$$v_1 = (v_1)_0(1 - gc)$$

and

$$v_2 = (v_2)_0(1 - gc)$$

respectively, where $c(= a + 2a_2)$ is the total concentration of protein expressed in base-molecules per unit volume, and g is a constant. Also the monomer and dimer particles have been treated as spheres[8], so that $v_2 = 1{\cdot}59\ v_1$. In the calculations by the second method, the hyper-sharp edge to the boundary on the higher concentration side of the maximum of the curves has been taken into account.

By plotting relative velocity, $v/(v_1)_0$, against relative concentration, gc, as in Fig. 1, it is possible to represent the whole family of curves on one diagram. The determining parameter is the quotient g/k ($= \omega$ say). It can be shown that for any system for which $\omega \gtrsim 1{\cdot}18$ the curve has no maximum, and the velocity falls steadily with increase of concentration. In this region $\omega \gtrsim 1{\cdot}18$, the two methods of calculation are equivalent.

Two practical conclusions can be drawn from the curves in Fig. 1. First, extrapolation backwards of the downward-sloping part of the curves leads to an intercept somewhere between the limiting sedimentation velocities of the monomer and the dimer. Identification of this intercept with the velocity of the dimer will suggest a false, and anomalously high, value for the frictional coefficient of the dimer[8].

Second, it appears that even a slight tendency to aggregate, far too slight for any tell-tale maximum in the curve, will be sufficient to reduce the downward slope measurably. In cases, therefore, where a change of *p*H, ionic strength or electrolyte causes a change in slope greater than would be expected from sedimentation potential effects[9], aggregation should be looked for. Fibrinogen[10] seems to be a case in point. Also, if appreciable differences in slope are found between the curves for rather similar proteins, as, for example, for myeloma globulins[11], for which the values of g could not be expected to differ very much, the cause is again likely to lie in differences in aggregation. The many unpublished records of sedimentation velocity-concentration curves could well repay a search for this effect.

Application of Pyramidone to Detection of Nitrous Acid

PYRAMIDONE (1-phenyl-2,3-dimethyl-4-dimethylaminopyrazolone-5) or antipyrine (1-phenyl-2,3-dimethylpyrazolone-5) have been used in analytical chemistry to detect copper, cobalt, and iron. But there are a few references to the application of pyramidone as a cation and anion reducer[1,2]. I have used a freshly prepared 5 per cent solution of pyramidone (Merck), to detect nitrous acid ions in the presence of other anions and cations.

Method 1. 3–4 drops of pyramidone solution and 1–2 drops of diluted (10 per cent) acetic acid were added to about 1 ml. of, for example, a solution of sodium nitrite or potassium nitrite (Schering–Kahlbaum). A violet coloration, not spreading in ether, chloroform, amyl alcohol, or carbon tetrachloride, appeared immediately or after a few seconds according to the amount of sodium or potassium nitrite present. If the quantity of nitrite ions is small, the reaction may be accelerated by heating. By means of this reaction it is possible to detect 0·0140 gm. of sodium nitrite in 1 litre of water, or 0·009 mgm. of nitrite/ml.

The presence of sulphuric, nitric, iodic, hydrochloric, phosphoric, boric, oxalic, citric, tartaric or hydrobromic acid ions does not impair the reaction. Hydroiodic acid ions give in such a case a brown sediment, which disappears after heating, and the solution turns violet. The appearance of the sediment is at the same time a proof of the presence of nitrites, since there is no sediment in their absence. The reaction is not retarded by the presence of a number of bi- and tri-valent metal ions. Silver ions and pyramidone give a blue-violet colouring. The detection of small quantities of nitrite in the presence of silver is accomplished by the addition of sodium chloride and then of pyramidone and acetic acid to the solution under examination. Ferric iron also interferes. But if the reaction proceeds in the presence of potassium fluoride (and tartaric acid as well), then the test with nitrites is positive. Mercuric salts and pyramidone give a white sediment not interfering with the detection of nitrite; mercurous salts are reduced to metallic mercury. If acetic acid is present in excess, the sediment is dissolved, and in the presence of nitrite ions the solution turns violet.

Method 2. In view of the fact that aqueous solutions of pyramidone decompose rapidly, a dry reagent was also used for the detection of nitrite. The reagent was prepared as follows: 1 gm. of pyramidone and 1·5 gm. of tartaric acid or citric acid are thoroughly mixed in a mortar and then kept in the dark, in tightly closed gallipots. A pinch of the reagent is added to the solution under examination and mixed with it. If nitrites are present, the solution turns violet.

Method 3. A 'wet' reagent in chloroform or alcohol can also be used. (*a*) A drop of the saturated, chloroform solution of pyramidone is added to the acidified solution under investigation and shaken. If nitrites are present in small quantities, the mixture must be slightly heated. The solution turns violet. (*b*) A few drops of a mixture composed of equal parts of saturated, alcoholic (anhydrous) solution of tartaric acid and the same solution of pyramidone are added to about 1 litre of the solution under examination. In the presence of nitrite, the solution turns violet.

Polyvinyl Benzoate Monolayers

MONOLAYERS of polyvinyl benzoate show strong film properties strikingly similar to those of vertically oriented fatty acids and unlike those of horizontally oriented polyvinyl acetate. The polymer was prepared by free-radical bulk polymerization at 82° C. Monolayers were studied at 25° C. on the film balance[1–3]. The spreading solvent was twice-distilled benzene.

Fig. 1 shows duplicate pressure-area isotherms for polyvinyl benzoate and a representative isotherm for polyvinyl acetate[4]. Polyvinyl benzoate gives a surprisingly small extrapolated area—0·38 m.^{2} per mgm., or about 9 Å.^{2} per monomer unit. Film thickness corresponding to this area averages 20 Å. As shown in Table 1, compressibility is not much greater than that for octadecylphosphonic acid[2]. Most unexpected, however, is the high collapse pressure of 53 dynes per cm.; it is much greater than those for many other polymers, somewhat greater than that for stearic acid, and the same as that for octadecylphosphonic acid. Surface pressures are unusually stable throughout the compression, and the film is rigid.

Polyvinyl acetate is typical of many horizontally oriented polar polymers; the isotherm gives a large extrapolated area that corresponds to a film thickness of only 5 Å. The film is highly compressible, and collapse takes place gradually at about 25 dynes per cm.—a pressure hitherto considered high for a film of horizontally oriented molecules.

The strong film properties of polyvinyl benzoate and the marked difference between the benzoate and acetate films are difficult to explain. One might

Table 1. MONOLAYER PROPERTIES

	Area		Collapse pressure (dynes/cm.)	Compressibility (cm./dyne)
	m.^{2}/mgm.	Å.^{2}/mol.		
Polyvinyl benzoate	0 38	9*	53	0 0056
Polyvinyl acetate	1·90	27*	25	0·0252
Stearic acid	0 43	20	42	0 0019
Octadecylphosphonic acid	0 40	22	53	0 0035

* Per monomer unit.

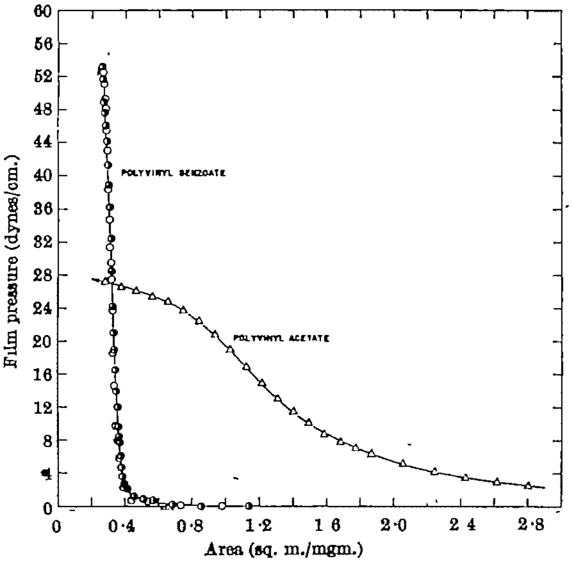

Fig. 1. Pressure-area isotherms for polyvinyl benzoate and polyvinyl acetate

expect aromatic rings to interfere with formation of a strong film, as they do in tri-*p*-cresyl phosphate and related compounds[2]. Molecular models of the polymer indicate that close packing of rings is possible; cohesive forces could be great between coplanar rings in contiguous parallel alignment. Another possibility is that rigid coils or folds rise from the surface and pack tightly. The small area per monomer unit would favour the coiling or folding picture.

Any branching in the polyvinyl benzoate probably could not account for the high collapse pressure. Polar branches would tend to orient horizontally as does the backbone chain. Moreover, a copolymer of vinyl benzoate and vinyl acetate, which presumably has less branching than the homopolymer of vinyl benzoate, gives films that collapse at similar high pressures.

Studies of mixed films may help explain the unusual properties of the monolayer of polyvinyl benzoate. An equiweight mixture with stearic acid gives reproducible monolayers that collapse at 36 dynes per cm.—well below the collapse pressures of the components alone—whereas a corresponding mixture of polyvinyl acetate and stearic acid collapses at a far greater pressure than do the components[4]. Evidently the vertically oriented fatty acid interferes with the packing of the benzoate polymer, in contrast to the marked strengthening produced by the interaction of the acid and the acetate polymer. An equiweight mixture of polyvinyl benzoate and polyvinyl acetate collapses at a pressure close to the average for the two components.

Further monolayer studies of polar polymers and mixtures should shed light on many complex problems of polymer structure and behaviour.

BIOCHEMISTRY

Vanadium Catalysis of the Oxidation of Catechol Amines, Dihydroxyphenylalanine and 5-Hydroxyindoles

IN the course of an investigation of the mechanism of enzymatic oxidation of serotonin (5-hydroxytryptamine) by human serum[1], we found that apparently identical chromatographic reaction products[2] resulted when this oxidation was catalysed non-enzymatically by cupric ion. We became curious as to what extent transitional metals other than copper catalysed this reaction, and expanded our investigation to include a study of the relative catalytic effectiveness of 18 transitional elements in the oxidations of related compounds of biological interest.

Glassware which had been washed in sulphuric acid – dichromate solution was treated with warm nitric acid, 0·01 *M* versene and 12–15 rinses of de-ionized water having a specific resistance $>10^6$ ohms at 25° C. All reagents were made up with de-ionized water. To 0·01 *M* concentrations of substrates in a 0·1 *M* acetate buffer at *p*H 6·0, catalytic amounts of transitional metals were added so that the final concentration of metal was 0·04 m*M*, or about 2γ of metal per ml. of reaction volume. Test-tubes were incubated at 37° C. and the development of colour was followed by measuring the light absorbance at 500 mμ in a Coleman Jr. spectrophotometer. The following metals were tested: copper (I and II), silver (I), zinc (II), lanthanum (III), vanadium (V), chromium (II), manganese (II), iron (III), cobalt (II), nickel (II), gold (III), cadmium (II), mercury (II), yttrium (III), zirconium (II) and palladium (II). The substrates employed were L-tryptophan, tryptamine, 5-hydroxytryptamine, D,L-5-hydroxytryptophan, 5-hydroxyindole-3-acetic acid, L-tyrosine (saturated solution), tyramine, L-3,4-dihydroxyphenylalanine, 3-hydroxytyramine, L-adrenalin and L-noradrenalin. In terms of the rapidity and intensity of colour development, the results were striking: vanadium was by far the most active catalyst of the oxidations of L-3,4-dihydroxyphenylalanine, 3-hydroxytyramine, noradrenalin and D,L-5-hydroxytryptophan. It was also the most active catalyst of the oxidation of adrenalin, although copper (I and II) were nearly as effective in catalysing this reaction. Colour also developed in the vanadium (V)–5-hydroxytryptamine and vanadium (V)–5-hydroxyindole-3-acetic acid systems, but in neither case was it nearly so intense or rapid as in the corresponding systems with cupric or cuprous ions. It was of considerable interest that colour did not develop in any of the systems containing tyrosine, tyramine, tryptamine and tryptophan, even after standing for a week.

Our interest naturally focused on vanadium, and we next tried a series of vanadium compounds including pentavalent V_2O_5 and $NaVO_3$ and the tetravalent $VOSO_4$ and $VOCl_2$. All were quite active in catalysing the oxidations of 5-hydroxytryptamine, 5-hydroxytryptophan, dihydroxyphenylalanine, 3-hydroxytyramine, adrenalin and noradrenalin. There was also slight activity in the vanadium–5-hydroxyindole-3-acetic acid systems. (After 72 hr., a light pink colour developed in test-tubes containing 5-hydroxyindole-3-acetic acid and vanadium salts, while duplicate controls remained colourless.) Niobium (V) and tantalum (V) (Na_2NbF_7 and K_2TaF_7 were obtained from the Kawecki Chemical Company,

Table 1. OXIDATION OF SOME TYROSINE AND TRYPTOPHAN DERIVATIVES IN THE PRESENCE OF VANADIUM AND COPPER

Manometric incubation of 8 m*M* substrates with 0·02 m*M* metals at *p*H 6 0 in 0 1 *M* acetate buffer at 40 0° C. Total flask volume = 2·6 ml. + 0·2 ml. 10 per cent potassium hydroxide in centre well. Shaking rate = 112 oscillations/min. μl. New York), the two other group V*a* elements, were also tested with the different substrates. Results were negative except that there was definite colour (first pink, then gun-metal grey and finally black) in the niobium–5-hydroxytryptophan system. This reaction was slow compared to that obtained when 5-hydroxytryptophan was oxidized in the presence of vanadium. The resulting colours were identical, and a black precipitate finally developed in each case.

We next measured consumption of oxygen in a Warburg apparatus; 8 m*M* substrates were incubated with 0·02 m*M* metals at *p*H 6·0 in an acetate buffer at 40·0° C. Most of the metals listed above were tested in this system. Table 1 represents typical results of many such experiments. Neither oxygen consumption nor colour occurred in any system containing tryptamine. There was considerable oxygen consumption and development of a yellow-brown colour in the copper (I and II) – 5-hydroxytryptamine systems. After 24 hr., although no oxygen was consumed, the vanadium (IV)– and vanadium (V) – 5-hydroxytryptamine systems also developed a yellow-brown colour. With incubation times longer than 24 hr., oxygen consumption was observed following the initial development of colour. In the case of 5-hydroxytryptophan, considerable oxygen uptake occurred in the presence of vanadium (IV and V), but in no other systems with the exception of niobium (V), in which there was a minimal oxygen uptake and a definite pink colour. Vanadium (IV and V) produced marked catalysis of the oxidations of the catechol amines. However, all these oxidations were also catalysed by copper. The only other findings of note were a considerable catalysis by manganese (II) and a slight catalysis by iron (III) of the oxidation of adrenalin.

None of these reactions occurred when the systems were incubated in an atmosphere of nitrogen for periods of up to 24 hr.; when incubated in an atmosphere of oxygen, the rate of development of colour and of consumption of oxygen increased in all cases.

Descending paper chromatography of the vanadium (V) – 5-hydroxytryptophan systems was performed in *n*-butanol/acetic acid/water (125 : 30 : 125, upper layer), but no indolic products could be found other than 5-hydroxytryptophan. Black pigment was noted at the origin.

Because of the relative specificity of the vanadium – 5-hydroxytryptophan reaction, we attempted to develop this reaction as an assay for small amounts of vanadium. While it has been possible to detect as little as 0·02γ of vanadium per ml. of buffered substrate solution, equimolar amounts of copper (II), iron (III) and cobalt (II) have been found to interfere with colour development. The oxidation of dihydroxyphenylalanine is even more sensitive to trace amounts of vanadium, but copper (II), iron (III), chromium (II) and cobalt (II) also catalyse this reaction, in decreasing order of effectiveness. If interfering ions could be removed chromatographically, these reactions might prove useful for the colorimetric determination of trace amounts of vanadium. The hydroxyl ion is a powerful catalyst of all these oxidations, so that *p*H control must be rigorous.

The chief actions of vanadium when administered intravenously to dogs are said[3] to involve the vascular system, with the production of intense peripheral vasoconstriction in the spleen, kidneys and intestines. 'Some time' after an intravenous injection is given, the kidney is said to show an irregular alternating constriction and dilatation of its volume. There is also a marked increase in peristalsis which is 'at once allayed' by injection of adrenalin. It is possible that one or more of the various vanadium-catalysed oxidations described in this communication play a part in the mediation of these important pharmacological actions.

This investigation was supported in part by Research Grant *H*-3174 from the National Heart Institute of the U.S. Public Health Service and by a grant from the State of Washington Fund for Biology and Medicine; a preliminary report has been made[4]. The technical assistance of Mrs. Grace Warren is gratefully acknowledged.

Diffusion of Proteins through Lipophilic Agar Gels

IF agar is used as a gelling agent, the aqueous phase of the gel should not be reduced below 38 per cent, otherwise the gel loses quickly its homogeneity and the necessary rigidity for handling it experimentally. Thus the intermediate gels, through which the diffusion occurs, contain 2 per cent agar ('Bacto-Agar', Difco Laboratories), 38 per cent aqueous buffer solution and 60 per cent of a lipophilic component. In gels Nos. V, VI and VII the latter consists of 48 per cent 1,2-propandiol and 12 per cent (by weight) of a further lipophilic component as indicated in Table 1. These additions raised the lipophilic properties considerably. The gel is formed by pouring 11 ml. of the hot, thoroughly mixed solution on a hot glass plate, such as are used in the 'Elphor' paper strip scanner. After setting, the gel is detached from the glass plate and laid upon the basis gel of 1 per cent agar in buffer. Drops of 2 per cent solutions of pure serum protein fractions, containing 200 μgm. of protein, are now placed, using

Table 1

* Approximate values.

an 'Agla' pipette, at regular intervals on the surface of the intermediate gel. After 48 hr. in a wet chamber the proteins having diffused into the basis gel are measured by a technique which I have already described[1,2] (Fig. 1). The following protein-fractions were used: serum albumin (mol. wt. 69,000); α_1-lipoprotein (mol. wt. approx. 250,000, ref. 3, 45 per cent lipoid-component, ref. 4; Behringwerke, Marburg/Lahn) and α_2-macroglobulin (mol. wt. 846,000, ref. 5; Behringwerke, Marburg/Lahn). Fig. 1 shows results of the standardized technique, allowing 7 diffusion tests per glass plate. If the intermediate gel contains only agar, average values should not differ by more than 5 per cent; with a lipophilic component in the gel the limit is rather 8 per cent. Microphotograms have shown that the latter gels are less homogeneous.

The values given for diffusion in Table 1 are in percentages of those obtained without diffusion (compare *a* in Fig. 1). Differences in dye-uptake of the various fractions are thus avoided. Viscosity of the buffered solutions (without agar) was measured in an Ostwald capillary viscosimeter immersed in a 20° C. constant-temperature glass water-bath. In order to obtain a measure of the lipophilic property, these solutions were shaken with ethanol-soluble aniline blue (Geigy, Basle). Optical density of the filtrate was measured in the Beckman *DU* on wavelength 600 mμ. Values for relative turbidity were measured by the Zeiss Stufenphotometer with a special attachment for the measurement of the stray light.

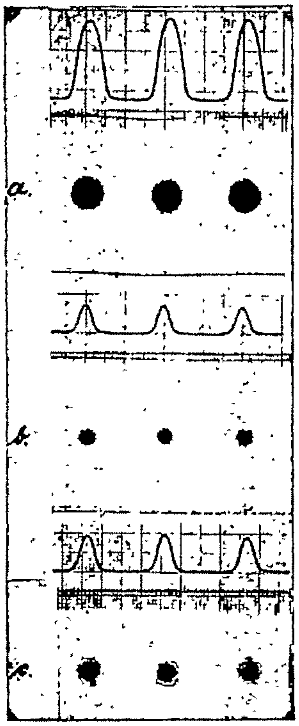

Fig. 1. *a*, Spots of α_1-lipoprotein, placed on a 1 per cent agar gel and stained with naphthalene black. Above each spot is the scanning as delivered by the Zeiss Extinktionsschreiber II; *b*, spots of α_1-lipoprotein after diffusion through a lipophilic agar-gel containing 1,2-propandiol and propanamid (see Table 1, gel No. V); *c*, spots of α_1-lipoprotein after diffusion through an agar gel containing 1,2-propandiol and hexane-1,6-diol (see Table 1, gel No. VI)

It follows that in gels with a lipophilic component (II, III, VI, VII), the diffusion of albumin remains stationary, whereas the diffusion of α_1-lipoprotein increases up to 450 per cent (comparison of gels I and VII). The chemical composition of this lipoprotein seems to be more important than particle-size. The latter interferes with the diffusion of α_2-macroglobulin in gels III, V, VI and VII; no measurable amount passes the intermediate gel within 48 hr. Work on the electrophoretic behaviour in analogous agar-gels is in progress.

Antioxidative Effect of Amino-Acids

Amino-acids are often mentioned as synergistic antioxidants. Their mechanism of enhancing the effect of primary antioxidants can be explained in different ways: by chelation of pro-oxidative metal traces[1] and by regeneration of oxidized primary antioxidants[2-4]. It has also been shown that amino-acids may play the part of synergistic antioxidants as natural constituents of food material[5]. On the other hand, there is a lack of systematic survey on a more general basis of this effect of amino-acids. Certain results have been published, which, however, refer to special conditions[6,7]. No data are available on the effect of amino-acids in absence of other antioxidative substances.

Experiments have been carried out to compare the antioxidative effect of several amino-acids and to study the dependence of this effect on certain factors, both in herring oil emulsions and in model systems with linoleic acid. Originally this work referred to oxidation in fatty fish. Variation of oxidizability in this material made it necessary to pass to the model

Table 1. RATE OF OXIDATION IN HERRING OIL EMULSIONS, WITH ADDED AMINO-ACIDS, RELATIVE TO THE RATE WITHOUT AMINO-ACID

Amino-acid	Molar 0·001	0·01
Glutamic acid	0·92	0·74
Methionine	0·88	0·72
Alanine	0·93	0·68
Asparagine	0·88	0·66
Valine	0·87	0·57
Aspartic acid	0·86	0·56
Serine	0·81	0·47
Lysine	0·69	0·87
Tryptophan	0·45	0·31
Histidine	0·41	0·17

4 ml. emulsion with 33 per cent oil, 1 per cent 'Tween' 20 and 1/150 mol. phosphate buffer, *p*H 5·6, 35° C.

systems. Oxidation has been followed by measurement of oxygen consumption by means of a manometric Warburg apparatus. In the case of herring oil and linoleic acid autoxidation, the course of oxygen consumption did not show any distinct induction period. Oxygen consumed per hour based upon consumption during several hours was taken as a measure of oxidation rate and the relation between oxidation rate with and without addition of the substances examined as a measure of their effect on oxidation.

In the case of herring oil, 10 of 11 amino-acids examined had antioxidative effects of varying degree. The effect was strongest with histidine (Table 1). It was pro-oxidative with cysteine. The tocopherol content of herring oil was determined to be about 0·01 molar.

The results obtained for autoxidation of linoleic acid show that amino-acids may have an antioxidative effect in the absence of tocopherol or other primary antioxidants. Amino-acids are consequently able to act as primary antioxidants themselves. Several amino-acids were examined and showed different effects. The effect is considerably dependent on *p*H : it was, in the case of alanine and histidine, relatively small at *p*H 7·5 and strong at *p*H 9·5 (Fig. 1).

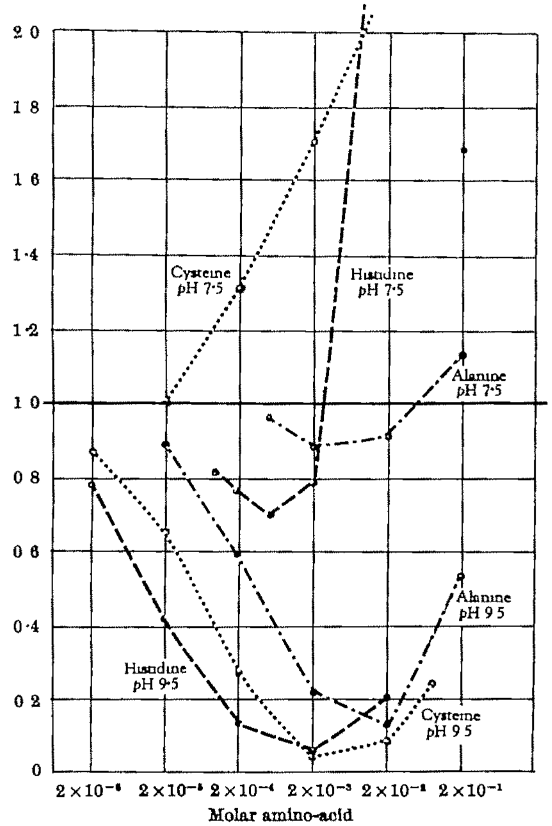

Fig. 1. Rate of oxidation of linoleic acid with amino-acid added, relative to the rate without amino-acid. 1 ml. 0 2 molar linoleate at 30° C.

With increasing concentration of amino-acid, the effect—after having passed a maximum (that is, a minimum oxidation-rate)—decreases and may, at *p*H 7·5, change from antioxidative to pro-oxidative. This phenomenon is well known from other primary antioxidants, for example, tocopherol. The threshold concentration for this inversion was different for the specific amino-acids examined. The effect of cysteine was at *p*H 7·5 pro-oxidative within the whole range. At *p*H 9·5 cysteine was strongly antioxidative like the other amino-acids examined. The results at *p*H 7·5 were in certain respects in agreement with the results of experiments with herring oil emulsions.

The amino-acids could also be shown to have a synergistic effect together with α-tocopherol. When α-tocopherol was added in a concentration which without amino-acids only slightly decreased the rate of oxidation, the relative effect of amino-acid addition was considerably greater than in the absence of tocopherol, at least at *p*H 7·5. At *p*H 9·5 the strong effect of amino-acid addition was only slightly re-inforced by tocopherol.

Work is going on regarding the effect of amino-acids in the hæmin-catalysed oxidation of linoleic acid. In this case quite a different type of curve for oxygen consumption, with a distinctly marked induction period, is obtained. The influence of amino-acid addition on the length of the induction period seems not to be correlated with the effects described above. A final account will be published later.

Mycosides: a New Class of Type-Specific Glycolipids of *Mycobacteria*

STUDIES by the combined techniques of chromatography and infra-red spectroscopy of the lipid content of 85 strains of *Mycobacteria* including human, bovine and avian species and representatives of the atypical acid-fast group[1], have led to the recognition that some of the compounds are limited in distribution to a single species of organism and may in fact serve to distinguish between the various species of *Mycobacteria*. The distribution of these substances in the various species of *Mycobacteria* studied is as follows: phthiocerol dimycocerosate present in the lipids of 28 out of 30 human strains studied; a compound called G_B [2,3] present in the lipids of 7 out of 7 bovine strains studied (G_B is accompanied by phthiocerol dimycocerosate in virulent bovine strains); a compound called G_A [4]

present in the lipids of 17/17 photochromogenic[1] strains; a compound called J_{av}[4] present in the lipids of 11/13 avian strains and also in the lipids of 3/6 non-photochromogenic strains. The purpose of this communication is to propose a more rational nomenclature for these substances.

Chemical investigation has shown that the three categories of substances provisionally named G_A, G_B and J_{av} are glycolipids, containing characteristic *O*-methylated 6-deoxyhexoses in glycosidic linkage.

We wish to propose the general name 'mycoside' for these compounds; a mycoside could be defined as 'a type specific glycolipid of Mycobacterial origin'. —G_A, characteristic of photochromogenic strains, should be called mycoside *A*. —G_B, characteristic of bovine strains, should be called mycoside *B*. —J_{av}, characteristic of avian strains, should be called mycoside *C*. The following preliminary data can be given concerning the chemical structure of these compounds:

(1) Mycoside *A* has been obtained as a nearly colourless solid melting at 105°, $[\alpha]_D^{20}$ − 37° ($CHCl_3$); C, 72·2; H, 11·3; OCH_3, 8·6; N, 0; P, 0 per cent. The ultra-violet absorption spectrum shows maxima at 222, 274 and 278 mμ (in hexane). Mycoside *A* contains three different *O*-methylated-6-deoxyhexoses, which have been identified as 2-*O*-methyl-fucose, 2-*O*-methyl-rhamnose and 2,4-di-*O*-methyl-rhamnose[5]. The lipid moiety of mycoside *A* is a mycocerosate of an aromatic alcohol.

(2) Mycoside *B* is a colourless wax, melting at 25° $[\alpha]_D^{20}$ − 22° ($CHCl_3$); C, 76·6; H, 12·0; OCH_3 4·3; N, 0; P, 0 per cent. Mycoside *B* has about the same ultra-violet absorption maxima as mycoside *A* (222, 274, 281 mμ). Mycoside *B* contains only one sugar, identified as 2-*O*-methyl-rhamnose[5]. The lipid moiety of mycoside *B* is a diester of two molecules of a branched chain acid fraction of mean molecular weight corresponding to $C_{22}H_{44}O_2$ with a phenolic alcohol (Demarteau-Ginsburg, H., and Lederer, E., unpublished experiments). In previous experiments[4] mycocerosic acid was found in mycoside *B*; it is possible that the nature of the acid varies in dependence of strain and culture medium.

(3) Mycoside *C* is a peptide–glycolipid[4] and can be separated by chromatography on silicic acid into several closely related compounds. One of these, melting at 200°, $[\alpha]_D^{20}$ − 31° ($CHCl_3$), has an approximate molecular formula $C_{72}H_{133}N_5O_{24}$; calculated for $C_{72}H_{133}N_5O_{24}$: C, 59·8; H, 9·1; N, 4·8; for 3 OCH_3 6·3 per cent; found: C, 60·1; H, 8·7; N, 5·1; OCH_3, 6·0 per cent.

This particular mycoside *C* preparation contains three different deoxyhexoses, of which two have been tentatively identified as 6-deoxytalose and 3,4-di-*O*-methyl-rhamnose; the third sugar is possibly a monomethyl ether of 6-deoxy-talose (MacLennan, A. P., unpublished experiments).

The peptide portion of mycoside *C* contains three different amino-acids linked in a pentapeptide; one molecule of D-phenyl-alanine, two molecules of *allo*-threonine and two molecules of D-alanine. The lipid moiety of mycoside *C* has not yet been obtained in a pure state, but seems to be a hydroxyacid of approximate molecular formula $C_{24}H_{48}O_3$. Two *O*-acetyl groups are also present in mycoside *C* and can be readily recognized in the infra-red spectrum by a band at 8·1μ.

A more detailed report on the chemical structure of mycoside *C* will be published soon[6].

We are indebted to Drs. M. Ikawa and E. E. Snell (Berkeley) for the determination of the configuration of the amino-acids obtained from mycoside *C*.

Hæmorrhagic Lipæmia in the Rat

Coleman and Beveridge[1] have recently directed attention to the influence of blood sampling on the level of plasma cholesterol in the rat. They observed that a diet containing merely corn oil did not increase the plasma cholesterol-level; but when it was combined with frequent blood sampling a significant increase followed. Further, blood sampling on alternate days even in the absence of fat in the diet was sufficient to cause an increase in the plasma

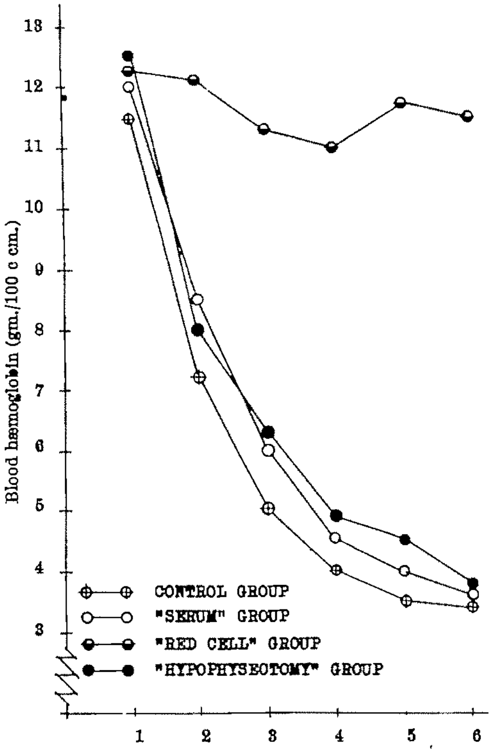

Fig. 1. Mean group values for blood hæmoglobin during the experiment

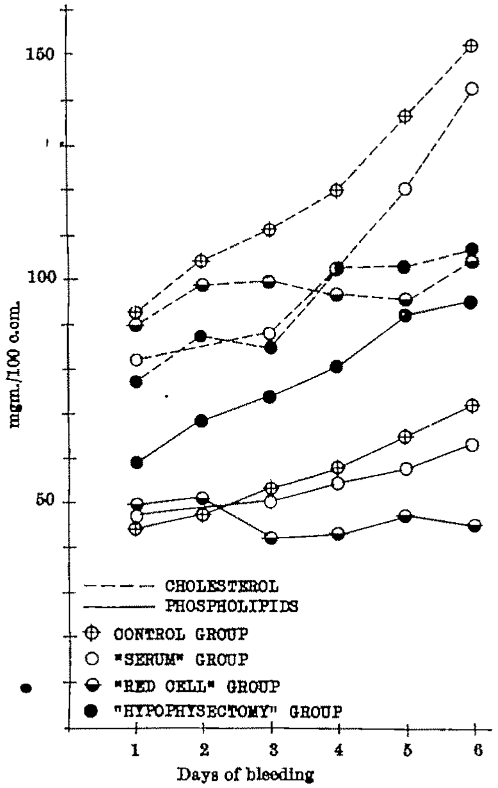

Fig. 2. Mean group values for serum total cholesterol and phospholipids during the experiment

cholesterol. Since some important earlier studies on hæmorrhagic lipæmia in experimental animals are not mentioned, we wish to give the following brief references and to present some additional data of our own.

Miettinen[2] has shown that in the rat bleeding causes a lipæmic turbidity of the serum and that relatively the greatest rise occurs in the total lipids. The phospholipids increase significantly more than the cholesterol. He further showed that the increase in cholesterol and phospholipids occurs chiefly in the α-2 lipoprotein fraction separated by paper electrophoresis. The administration of heparin to such lipæmic rats caused changes which were opposite to those resulting from bleeding[3]. In these experiments the bleeding was heavy enough to make the rats markedly anæmic.

In an extensive and thorough work Starup[4] showed that the development of hæmorrhagic lipæmia in the rabbit correlated best to the changes in the blood hæmoglobin-level. A similar lipæmia resulted from exposure of the animals to low atmospheric pressures. Starup regarded hypoxæmia as the cause of the lipæmia.

We have recently investigated some of the factors connected with the development of hæmorrhagic lipæmia in the rat[6]. Three groups of rats, each consisting of eight intact male animals on a standard low-fat diet, were subjected to a daily withdrawal of an amount of blood corresponding to 2 per cent of body-weight. The first group served as a control group and developed a marked anæmia, together with a definite increase in the serum cholesterol and phospholipid concentrations and visible lipæmia. The animals of the second group received after each bleeding an amount of rat serum approximately corresponding to the amount withdrawn. In this group anæmia and lipæmia developed similarly to the control group. The rats of the third group received after each bleeding an amount of washed red cells sufficient to prevent the development of anæmia. In this group no lipæmia occurred. These results are in accordance with those obtained on rabbits by Starup[4,5].

A fourth group of rats consisted of seven hypophysectomized animals which were bled sufficiently to produce an anæmia of the same degree as that of the control rats. Also in hypophysectomized rats the bleeding caused an increase in the serum cholesterol- and phospholipid-levels, but in the sera of these animals there occurred no visible turbidity.

It thus seems probable that the anæmic anoxia is the cause of the hæmorrhagic lipæmia. As to the mechanism of development of the hæmorrhagic lipæmia, it cannot be considered to be due solely to a reaction dependent on the hypophysis, such as stress, since the serum cholesterol- and phospholipid-levels rose also in the hypophysectomized rats. The lack of an apparent increase of serum neutral fats in these rats can be explained in several ways, for example, by an acceleration in 'the lipæmia clearing activity' in hypophysectomized rats[7], or by an impaired neutral fat mobilization from the depots. There remains the possibility, however, that in bleeding anæmia the elevation of neutral fats, on one hand, and that of cholesterol and phospholipids, on the other hand, are mediated by different mechanisms, the former possibly through the hypophysis.

PHYSIOLOGY

Action Potentials in Active Tissue with Delayed Potassium Permeability

In 1952, Hodgkin and Huxley[1] published a model which describes with considerable accuracy the electrical activity of nerve axons. The action potential in this tissue is accounted for by a large temporary increase in the permeability of the cell membrane, first to sodium ions, and then a millisecond or so later to potassium ions.

In the course of an investigation into the applicability of this model to the action potential in cardiac muscle tissue, I was led to explore the solution to the Hodgkin–Huxley equations when the increase in potassium permeability is suppressed. Under this condition active tissue was found to have two stable states which may be understood by reference to Fig. 1.

The equation to be solved[1] is:

$$C\frac{\mathrm{d}V}{\mathrm{d}t} + G_{\mathrm{K}}(V - V_{\mathrm{K}}) + g_{\mathrm{Na}}\, m^3 h\,(V - V_{\mathrm{Na}}) + g_l\,(V - V_l) = 0 \qquad (1)$$

The first term is the capacity current, the remaining terms give the potassium, sodium and leakage currents respectively.

For a steady state the first term is zero, and for simplicity I put the leakage current equal to zero also as it is in any event quite a small term. V_{K} and V_{Na} are reference potentials depending on the internal and external ionic concentrations, which in squid axon are $V_{\mathrm{K}} = +12$ mV., $V_{\mathrm{Na}} = -115$ mV.

If the potassium permeability G_{K} is constant, then the curve representing the second term in the above equation is a straight line, which has been drawn with sign reversed in Fig. 1 (*AB*). In the term giving the sodium permeability, g_{Na} is a constant and *m* and *h* are functions of *V* and *t* given by Hodgkin and Huxley. The steady-state values of these variables have been taken from ref. 1 and the resulting current is plotted on Fig. 1.

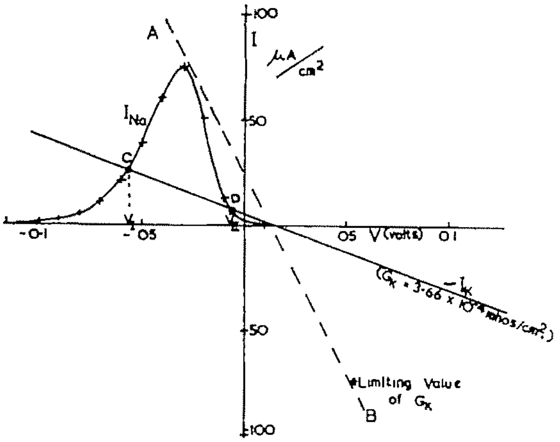

Fig. 1. Equilibrium values of sodium and potassium currents for various voltage displacements from the resting value and for constant potassium conductivity. The potassium current is plotted with sign reversed, and the intersections of these two curves give possible equilibrium values of V, V_{I} and V_{II}

The voltage corresponding to the steady state will then be given by the intersection of these two lines. It is immediately obvious that provided G_{K} is less than a certain limiting value, there are two points of intersection *C* and *D* corresponding to two stable potentials V_{I} and V_{II}. Fig. 1 has been drawn with the value $G_{\mathrm{K}} = 3{\cdot}66 \times 10^{-4}$ mhos/cm.^{2}, the resting value measured by Hodgkin and Huxley, when the values of V_{I} and V_{II} are found to be $V_{\mathrm{I}} = -56$ mV., $V_{\mathrm{II}} = -6$ mV. The limiting value of G_{K} corresponding to the dotted line in Fig. 1 is found to be $G_0 = 1{\cdot}9 \times 10^{-3}$ mhos/cm.^{2}.

The general solution to equation 1 for G_{K} = constant $= 3{\cdot}66 \times 10^{-4}$ mhos/cm.^{2} has been integrated using the fast digital computer *Silliac* in the School of Physics, University of Sydney. The result is shown in Fig. 2 and bears a striking resemblance to the early part of the action potential of Purkinje fibres[2].

Tasaki and collaborators[3-5] have presented evidence demonstrating the existence of a bistable state of the nerve membrane under certain conditions. For example, Tasaki and Hagiwara[3] showed that the effect of tetraethylammonium is to prolong the action potential in the squid axon and abolish the delayed rise in potassium conductivity. These authors were unable to explain their results in terms of the Hodgkin–Huxley model, but it appears that they can be so explained along the lines indicated above. Similarly, the other conditions for producing bistable states[4,5] may be understood in terms of Fig. 1.

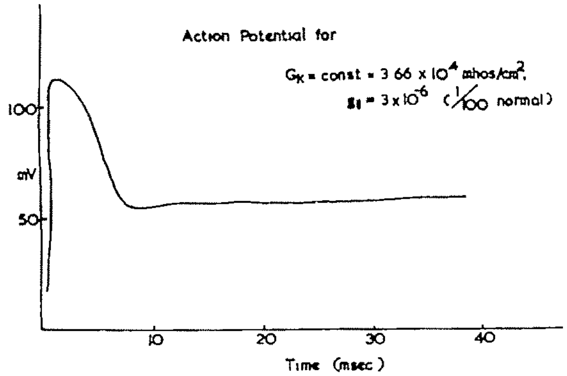

Fig. 2. Form of action potential calculated for G_{K} = constant = 3·66 × 10^{-4} mhos/cm.^{2}. Following the initial spike due to the sodium current, the potential settles down at the alternative steady level (V_{I} of Fig. 1)

A fuller description of these results is in the course of publication.

Thyroid-Powder Feeding and Liver Nitrogen in Mice

IT is known that thyroid hormone increases liver-weight in animals[1], accelerates the regeneration of liver in partially hepatectomized animals[2] and induces changes in liver cells representing typical growth[3]. The effect of thyroid hormone on liver nitrogen appears to have been less well studied. We have therefore investigated the effect on liver protein and glutamine in mice of feeding thyroid powder. Glutamine is found in relatively large quantities in various tissues, and the ability of these tissues both to synthesize and to break down proteins suggests that glutamine may serve as an important reservoir of ammonia nitrogen[4].

The experiments were carried out in male mice of Swiss strain weighing 23–25 gm. The animals were fed a standard stock food *ad libitum*. To produce hyperthyroidism, 0·5 per cent desiccated thyroid powder was added to the standard food for 10 days. On the eleventh day the animals were autopsied and liver-weight, protein and glutamine were measured. Liver protein for homogenized tissues was determined by the Kjeldahl–Pregl method. For determination of glutamine, the homogenates were deproteinized by the Folin–Wu method, and glutamine in the filtrate was determined by Whitehead and Whittaker's method[5]. The results are shown in Table 1. Increased weight of liver was observed in thyroid-fed animals. This increase is not related to a change

Table 1. EFFECT OF FEEDING THYROID POWDER ON LIVER-WEIGHT, PROTEIN AND GLUTAMINE

Treatment and No. of animals	Body-weight (gm.)		Liver: Weight		Liver: Protein†		Liver: Glutamine‡	
	Before	After	Actual (gm.)	Relative*	(mgm./100 gm.)	Total (gm.)	(mgm./100 gm.)	Total (mgm.)
Control (33)	24	23·9	1·187±0·090	4·98±0·01	23·50±0·30	0·278±0·030	106·3±5·1	1·250±0·071
Experimental (36)	24	23·7	1·346±0·080	5·85±0·03	23·43±0·22	0·321±0·020	126·4±8·1	1·620±0·084

* Relative liver-weight is the actual weight of liver per 100 gm. body-weight.
† Liver protein is calculated in gm. per 100 gm. Total protein is that in the whole liver in gm.
‡ Glutamine is calculated in mgm./100 gm. Total glutamine is the estimated value in mgm. in the whole liver.

in body-weight, since the relative liver-weight is also increased. The gain in liver-weight is also accompanied by a significant increase in total protein ($P < 0·02$), but there is no change in the percentage of liver protein. The increase in liver glutamine was more pronounced; there is a significant increase in percentage ($P = 0·02$) as well as in the total liver glutamine ($P = 0·001$).

These findings are in conformity with the fact that hypophysectomy reduced kidney glutamine in dogs, but the administration of growth hormone produced increased glutamine in kidneys and plasma along with nitrogen storage and gain in weight[4].

If glutamine is taken as a measure of the metabolic nitrogen pool, the action of thyroid hormone in promoting protein anabolism may be associated with the rise in the amount of glutamine.

Effect of Curare on Conduction in Myelinated, Isolated Nerve Fibres of the Frog

THE inhibitory effect of curare on the transmission of nerve impulses across myoneural junctions is generally attributed to its binding with the specific acetylcholine receptors in the motor end-plate membranes in competition with the acetylcholine, thereby preventing the ester from exerting its depolarizing action. Since the work of Claude Bernard, it has been known that curare acts specifically on the motor end-plates without any effect on axonal conduction. The failure of externally applied acetylcholine to affect conduction of nerve fibres was explained by Nachmansohn[1] as being due to permeability barriers surrounding the axon which are impermeable to lipid-insoluble compounds, such as methylated quaternary nitrogen derivatives, and cannot reach, therefore, the interior of the axon. These permeability barriers also explain the absence of any action of curare on axonal conduction: if monoquaternary ammonium salts are unable to penetrate these barriers, it is certainly to be expected that diquaternary salts will not enter. This does not indicate that the acetylcholine receptor upon which curare is supposed to act at the myoneural junction is not present and functional in the axon, only that it cannot be reached. If this viewpoint is correct, then diquaternary compounds which have two cationic nitrogens at the proper distance but are in addition soluble in lipid, such as stilbamidine, should have curare-like action. Block of conduction by stilbamidine was obtained by Bergmann, Wilson and Nachmansohn[2] on the axon, and by Schoffeniels and Nachmansohn[3] on the conducting membrane of the electroplax of *Electrophorus electricus*.

Another possibility to test this point of view is the use of a preparation where there is reason to believe that the structural barrier around the conducting membrane is relatively weak. Electron-microscope studies have revealed that at the nodes of Ranvier the conducting membrane is covered by a very thin structure. *d*-Tubocurarine chloride was applied to a single nerve fibre preparation as described by Stämpfli[4]. Conduction was blocked reversibly in a concentration of 10^{-3} *M*. The time necessary for this effect across the Ranvier node varied between 1 and 15 min. In cases where the blocking time was longer than 7 min., the reversibility was poor. Fig. 1*a* shows the effect of 10^{-3} *M* curare after 40 sec. The duration of the spike is significantly increased. After 100 sec. conduction was completely blocked (*b*). Partial recovery was obtained after rinsing the node with Ringer's solution for 60 sec.; 4 min. later, the height of the spike was restored to its original value, but the duration was still prolonged.

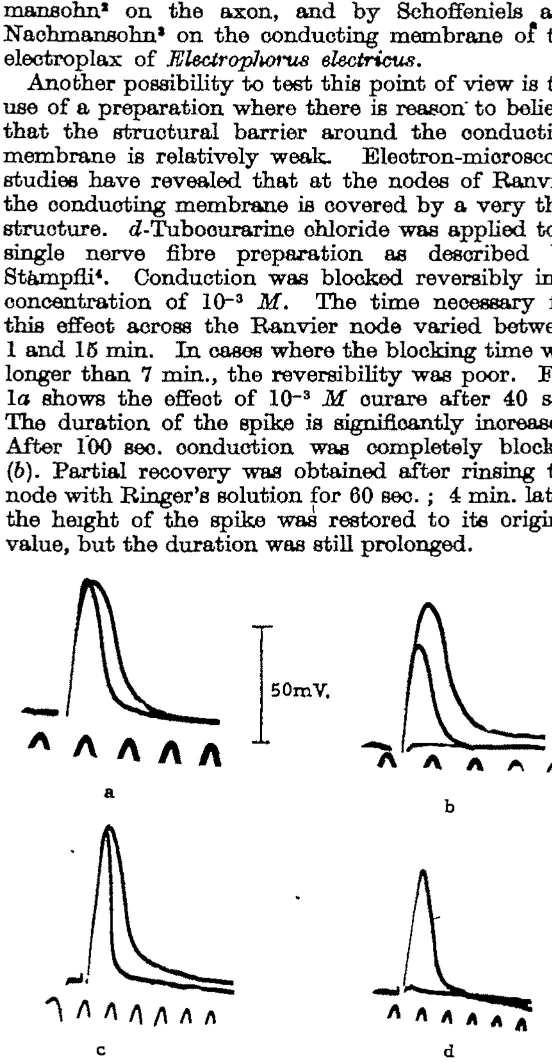

Fig. 1. Electrical activity at the node of Ranvier of a single nerve-fibre preparation of *Rana pipiens* exposed to *d*-tubocurarine chloride.
(*a*) and (*b*), 10^{-3} *M*, (*c*) and (*d*), 5×10^{-3} *M*. (*a*) 40 sec. after exposure, increased duration of spike; (*b*) after 100 sec., complete block of conduction. Return to Ringer's solution brings spike partially back; after 4 min. height of spike has returned to normal although the duration is still increased; (*c*) 5 sec. after curare the height of spike is increased and the duration prolonged. (*d*) after 40 sec., complete block of conduction. After 60 sec. in Ringer's solution, height of spike returns to normal. $t = 24°$ C., time, 1,000 cycles/sec.

In some cases 10^{-3} *M* curare had only a small effect on the duration of the spike and did not cause a block even after exposure for 15 min. In these cases curare in a concentration of 5×10^{-3} *M* had a strong and rapid effect. In Fig. 1*c* the duration of the action potential is prolonged after 5 sec. Block of conduction occurred after 40 sec. (Fig. 1*d*). After 60 sec. in Ringer's solution the spike has returned, although not yet to its original height. Repeated exposure of the same fibre to the same concentration of curare brought the blocking time down to 5 sec. Fibres which did not respond to 1×10^{-3} *M* curare but did to 5×10^{-3} *M* showed block after 1–2 min. when exposed again to 1×10^{-3} *M*.

d-Dimethyltubocurarine chloride, which is slightly more soluble in lipid than is *d*-tubocurarine, was also used, but no significant difference was found. Eserine blocks conduction of the node of Ranvier in low concentrations (30–40 µgm./ml.)[5]. This tertiary nitrogen derivative penetrates readily into the interior of the axon. Prostigmine also causes a block, but the concentration required for the effect is about tenfold higher (about $1{\cdot}7 \times 10^{-3}$ *M*, equivalent to ~ 500 µgm./ml.) and longer periods of exposure are needed[6]. Prostigmine, being a methylated quaternary nitrogen, does not penetrate into the interior of the nerve fibre[1]. Both compounds are *in vitro* almost equally strong inhibitors of acetylcholinesterase. The quantitative differences observed on the Ranvier node as to time and concentration may be attributed to differences in the rate of penetration. It is therefore not surprising that curare, too, requires relatively high concentrations. But the fact that it blocks reversibly electrical activity at the node of Ranvier supports the view of Nachmansohn that the role of the acetylcholine system is basically similar in axonal conduction and in synaptic transmission.

Level of Sulphydryl Compounds in Rat Liver following Feeding with Goitrogenous and Non-goitrogenous Cabbage

IN work on the relationship between the goitrogenous activity of cabbage and sulphate utilization from nutrient media[1,2], we have now followed, among other factors, the total sulphydryl compounds in the liver of experimental rats, by means of polarographic estimation[3]. The rats were given a goitrogenous and a non-goitrogenous variant of cabbage (*Brassica oleracea* var. *capitata*), grown in sand culture with nutrient solutions. The nutrient solution for the non-goitrogenous variant of cabbage contained 1 mgm. equivalent of sulphate and that used for the goitrogenous variant 25 mgm. equivalent of sulphate per 1 l. of solution. The other nutrient substances, both macro- and micro-elements, were present in equal amounts in both solutions.

Goitrogenicity of the cabbage thus cultivated was tested experimentally on white female rats of the Wistar strain, average weight 120 gm. One group of 20 rats received a daily ration of non-goitrogenous, another group of 20 rats had the goitrogenous variant of cabbage. In addition, both groups received Larsen's diet without any water. The controls, a group of 10 rats, were fed on Larsen's diet and had water to drink. The experiment lasted 33 days. 24 hr. before being killed the animals were given 20 µc. of iodine-131 intraperitoneally in 0·5 ml. of physiological solution; during these 24 hr. the animals were kept fasting, but all had water to drink. Beside the sulphydryl compounds, a series of determinations were made from which the goitrogenous activity of the particular variants of cabbage could be inferred (Table 1).

Table 1

Type of estimation	Controls* ($n = 10$)	Rats fed on non-goitrogenous variant of cabbage ($n = 20$)	Rats fed on goitrogenous variant of cabbage ($n = 20$)
Total sulphydryl compounds in liver expressed in mgm. of SH-glutathione/100 gm. of fresh liver	322·7 ± 62·4†	258·2 ± 14·5	625·9 ± 73·4
Percentage of epithelial cells in histological preparation of the thyroid	43·7 ± 4·9	41·5 ± 2·8	51·9 ± 5·8
Percentage of colloid in cells of histological thyroid preparation	44·1 ± 5·7	44·2 ± 8·4	34·5 ± 6·9
Iodine-131 uptake by thyroid as percentage of dose administered	44·2 ± 10·0	48·1 ± 11·2	70·4 ± 16·1‡
PBI-131 content in 1 ml. of serum as percentage of dose administered	0·034 ± 0·01	0·0258 ± 0·003	0·108 ± 0·059‡
Thyroid weight in mgm./100 gm. body-weight	9·8 ± 1·1	10·1 ± 1·9	10·6 ± 1·7

* *n*, number of rats in the experiment.

† Average + standard deviation.

‡ Increased uptake of iodine-131 by the thyroid and PBI-131 in 1 ml. of serum is accounted for by the unblocking effect of goitrogens on the thyroid as a result of a 24-hr. exclusion of cabbage from the diet.

Total sulphydryl compounds in the liver were measured immediately following the death of the animals. 4–5 gm. of liver were homogenized with 40–50 ml. of 1 per cent acetic acid and the anode wave of sulphydryl compounds was registered polarographically in 10 ml. of filtrate on a Heyrovský polarograph, type *V* 301. The quantitative evaluation of the waves of sulphydryl compounds was carried out by adding standard solutions of SH—glutathione.

The results in Table 1 and Fig. 1 show that rats fed with the goitrogenous variant of cabbage store

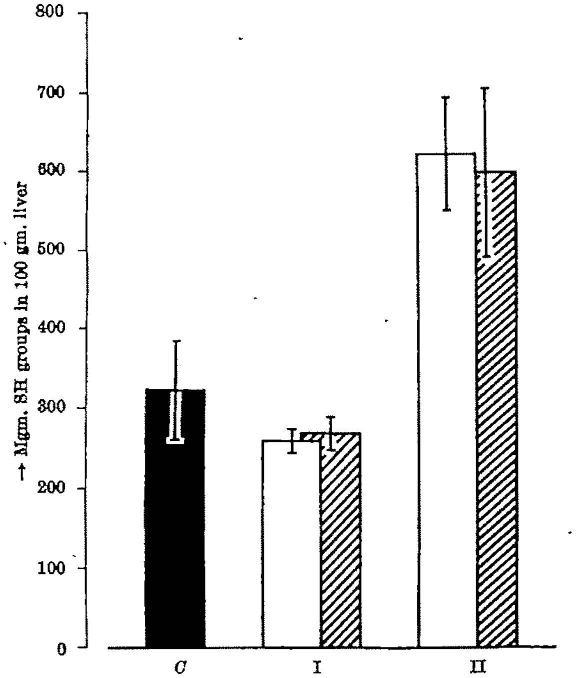

Fig. 1. Total sulphydryl compounds in experimental rat livers. *C*, Control group; I, groups of rats fed with non-goitrogenous variant of cabbage; II, groups of rats fed with goitrogenous variant of cabbage. Individual columns indicate average value with standard deviation. Blank columns indicate values obtained for rats consuming cabbage heads; shaded columns for those consuming green cabbage leaves

in the liver twice as much ($P \leqq 0{\cdot}0001$) total sulphydryl compounds, expressed in terms of glutathione, as do those fed on non-goitrogenous cabbage, or on Larsen's diet.

One of the principal effects of goitrogens on entering the organism is a lowered production of thyroid hormone, bringing about a 'hypothyroid' condition in the whole organism, a lowered over-all metabolic rate and lowered oxygen utilization by the tissues. The inhibiting effect of goitrogens on oxygen uptake by tissues *in vitro* is likewise known[4]. This inhibitory influence of goitrogens may be a causative factor in the increased level of total sulphydryl compounds, that is, of the protein and non-protein sulphydryl compounds in the liver of rats fed with a goitrogenous variant of cabbage. There probably ensues inhibition of the oxidases of SH-glutathione and other sulphydryl compounds in the liver of rats fed with a goitrogenous variant of cabbage.

Since a marked increase in the total sulphydryl compounds occurred after consumption of the goitrogenous variant of cabbage only, it may be possible to use the estimation of total sulphydryl compounds in the liver of experimental animals as a test of the goitrogenicity of vegetable foodstuffs, provided, of course, that account is taken of the specificity of the test. Besides a marked increase in sulphydryl compounds in the liver after consumption of the goitrogenous variant of cabbage, there is probably also an increase in total sulphydryl compounds in the blood and other organs, too, as found by Houssay, Martinez and Caputto[5] following administration of thiouracil, and by Capra[6] after methylthiouracil; therefore a diet of goitrogenous cabbage may give protection from the effects of ionizing radiation.

We are grateful to Mr. Š. Kaločai and Miss J. Horváthová for their technical assistance.

Synergetic Action of 2(*o*-Methoxyphenoxymethyl)-5-Oxazolidone on Morphine, Dihydrocodeine and Aminopyrine Analgesia

2(*o* - Methoxyphenoxymethyl) - 5 - oxazolidone (metoxadone), a substance synthesized by us[1] (cf. Argentine Patent No. 118.613, April 21, 1957—Oct. 29, 1959), produced prolonged muscle relaxation and anticonvulsive effects[2,3]. Gray *et al.*[4] found that this substance reduced the spontaneous motor activity and caffeine hyperactivity of mice and specifically blocked their conditioned avoidance reaction. According to its behaviour in the avoidance conditioning test, metoxadone belongs to the group formed by chlorpromazine and its congeners, reserpinoid *Rauwolfia* alkaloids and morphine[5].

We therefore studied the synergetic effect of metoxadone on central analgesic actions of drugs such as morphine, dihydrocodeine and aminopyrine, because a similar effect is characteristic for chlorpromazine and its congeners[6,7], but not for reserpinoid alkaloids which antagonize morphine analgesia[8].

In our experiments we employed the hot-plate test of Woolfe and Macdonald[9], modified by Eddy *et al.*[10,11]. The plate was heated to a constant temperature of 59·5° C. and the time until the mice lifted their hind legs twice was recorded as 'permanence'. The results are shown in Tables 1, 2 and 3.

AP alone, 200·0	3·9 ± 0·8	significant,	*P* = 0·01
AP, 50·0 + MET, 10·0	3·5 ± 1·6	not significant,	*P* = 0·05

Table 1 shows that metoxadone has a marked synergetic effect on dihydrocodeine analgesia. 12·5 mgm./kgm. dihydrocodeine is potentiated by 25 mgm./kgm. metoxadone (a dose without any analgesic effect of its own), for the combination was as active as a dose of dihydrocodeine twice as high (25 mgm./kgm.). 50 mgm./kgm. metoxadone increased the effect of 12·5 mgm./kgm. of dihydrocodeine more than four times.

Table 2 shows that relatively low doses of metoxadone potentiated the effect of 1·25 mgm./kgm. morphine hydrochloride more than twice; the effect of 2·5 mgm./kgm. morphine salt alone was still somewhat less (2·7 sec.) than that of the combination (3·4 sec.). A higher dose of metoxadone (10 mgm./kgm.) increased the effect of morphine more than four times. (Permanence prolongation of the combination: 9·6 sec.; that of a fourfold dose of morphine alone 4·0 sec.)

Table 3 shows that the effect of aminopyrine is enhanced nearly four times by metoxadone.

According to our results, metoxadone markedly increases the analgesic actions of dihydrocodeine, morphine and aminopyrine.

HÆMATOLOGY

Variations in Electrophoretic Position of Haptoglobin Mixtures in Agar-gel Electrophoresis

BY means of agar-gel electrophoresis, sera can be put into different haptoglobin groups. Sera belonging to *Hp* 1-1 give a fast migrating spot stainable with benzidine, while sera belonging to *Hp* 2-2 have a slowly migrating component and sera belonging to *Hp* 2-1 give a spot occupying an intermediate electrophoretic position. The spots are easily stained with a benzidine reagent if hæmoglobin has been added to the sera before electrophoretic separation[1].

When sera belonging to *Hp* 2-1 as determined by starch-gel electrophoresis[2] with a discontinuous buffer system[3] were investigated in agar-gel electrophoresis[1], it was found that these sera could be divided into further groups depending on variations in electrophoretic positions of the spot stainable with benzidine.

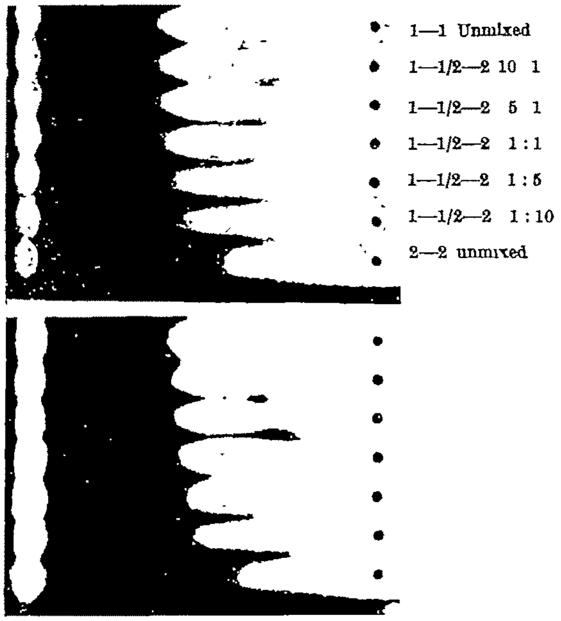

Fig. 1. Agar-gel electrophoresis of sera belonging to *Hp* 1-1 and 2-2 and mixtures of these sera in different relative amounts. To the far left is the albumin spot. The circular holes represent the point of application. The photographs represent duplicate experiments

Sera presenting a weak, or even absence of the *Hp* 1-1 band in starch-gel electrophoresis were found, in agar-gel electrophoresis, to give a spot more displaced towards the cathode than sera presenting a strong *Hp* 1-1 band but weak other bands characterizing the *Hp* 2-1 type in starch-gel electrophoresis.

In Fig. 1 duplicate separations of mixtures of a serum belonging to *Hp* 1-1 and *Hp* 2-2 in different relative amounts are shown. By mixing these sera in different relative amounts, varying electrophoretic positions of the spot stainable with benzidine will be obtained as judged by the position of the part of the spot which is situated nearest to the anode.

Thus, if the serum belonging to *Hp* 1-1 is quantitatively predominant in the mixture, for example, in the ratio of 10 : 1, a rapidly migrating spot will be obtained, which, however, migrates slightly slower than the spot of the unmixed *Hp* 1-1 serum, but more rapidly than a mixture of these sera in the proportions of 5 : 1. When the same mixtures were subjected to starch-gel electrophoresis, no differences in electrophoretic positions of the haptoglobin bands were seen. If serum belonging to *Hp* 1-1 was mixed with the serum belonging to *Hp* 2-2 in the relative amounts of 10 : 1, only a single *Hp* 1-1 band was seen in starch-gel electrophoresis under the experimental conditions employed. Therefore it seems as if the agar-gel electrophoretic technique is slightly more sensitive than the starch-gel electrophoretic technique as carried out in this laboratory.

If the ratio between *Hp* 1-1 and *Hp* 2-2 is 1 : 20 or greater, the electrophoretic position of the mixture is identical with that of an unmixed serum belonging to *Hp* 2-2.

Thus, within certain limits, the electrophoretic position of the haptoglobin spots in mixtures of sera belonging to *Hp* 1-1 and 2-2 will vary, depending on relative amounts of these sera in the mixture. This is not the case when the same mixtures are subjected to starch-gel electrophoresis.

Therefore it seems as if the agar-gel electrophoretic technique might be a valuable supplement to starch-gel electrophoresis, especially as regards sera, where suspicion might exist that the phenotype as revealed by starch-gel electrophoresis does not correspond to the genotype as indicated by, for example, family studies[4]. My work on some mother–child material also seems to indicate that, especially among children, haptoglobin grouping might be difficult, as originally pointed out by Smithies[2]. In some instances, repeated starch-gel electrophoretic investigations of certain sera did not demonstrate any haptoglobin in these sera, although in agar-gel electrophoresis haptoglobins were demonstrable enabling us to group these sera (unpublished work).

The fact that variations in electrophoretic positions of components in agar-gel electrophoresis as well as in immunoelectrophoresis[5] may depend on quantitative relations between electrophoretically different molecule populations, giving rise to a single spot with the technique employed, may be of theoretical interest when the 'microheterogeneity' of different components is studied, and of practical importance when further electrophoretic differences are found in different human sera.

Thus, it has recently been found that another component in the α_1-globulin region presents electrophoretic differences when different sera are investigated in agar-gel electrophoresis and developed with an indoxyl–acetate reagent. In general, sera can be grouped into a fast, a slow and an intermediate type, depending on the electrophoretic position of this component[6]. It was found that sera belonging to the intermediate group gave rise to spots with slightly varying electrophoretic positions characteristic for the serum investigated (unpublished work).

In analogy with the findings here, it seems suggestive that this intermediate group depends on the concomitant presence of the fast and slow components although in different relative amounts, thereby allowing a further sub-grouping within this group, as has been the case with sera belonging to *Hp* 2-1.

Further work is in progress to investigate the influence of quantitative factors on the electrophoretic position of proteins in agar-gel and starch-gel electrophoresis.

Oxygen Equilibrium of Hæmoglobin from *Thunnus thynnus*

FEW data can be found in the literature dealing with the functional properties of hæmoglobin of lower vertebrates[1–3]. Moreover, these investigations were carried out using whole blood or unpurified hæmolysate as working material, particularly in the case of fishes; this procedure may make the interpretation of the results misleading since the blood of these animals rapidly deteriorates after collection[3].

In this communication we report results on the oxygen equilibrium of crystalline hæmoglobin from *Thunnus thynnus*. Crystalline hæmoglobin was prepared from freshly collected blood as previously described[4], and was stored under saturated ammonium sulphate. Since during the preparation and storage the hæmoglobin is in part transformed into the ferric form, in all cases, before the determination of the oxygen dissociation curves, the pigment was completely reduced by an enzymic system[5].

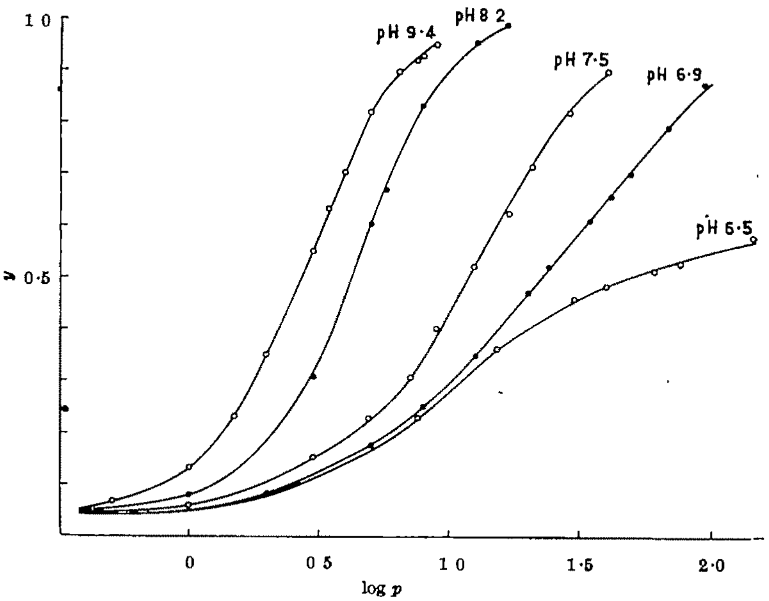

Fig. 1. Oxygen dissociation curves of *Thunnus* hæmoglobin at different values of pH at 20° C.; *tris*(hydroxymethyl)amino-methane buffers, ionic strength 0·1; hæmoglobin concentration: $2 \cdot 5–3 \times 10^{-4}$ *M* (as Fe); $y = \frac{(\mathrm{HbO_2})}{(\mathrm{Hb}) + (\mathrm{HbO_2})}$. p, partial pressure of oxygen in mm. mercury

The oxygen dissociation curves were determined by the spectrophotometric method previously described[5].

In all the conditions the pigment was stable, and the spectrophotometric data obtained during the progress of oxygenation could be ascribed to the presence of only hæmoglobin and oxyhæmoglobin.

Fig. 1 shows the oxygen dissociation curves of *Thunnus thynnus* hæmoglobin at different pH's. It may be seen that on varying the pH both the shape of the curve and the oxygen affinity change greatly. At alkaline pH's the curve is sigmoid in shape, but the inflexion rapidly decreases with lowering of the pH-value. Indeed, the curve of the dissociation factor y versus oxygen partial pressure was found to be hyperbolic at pH 6·9; below this value of pH, the curve, for values of y greater than 0·3, tends to become

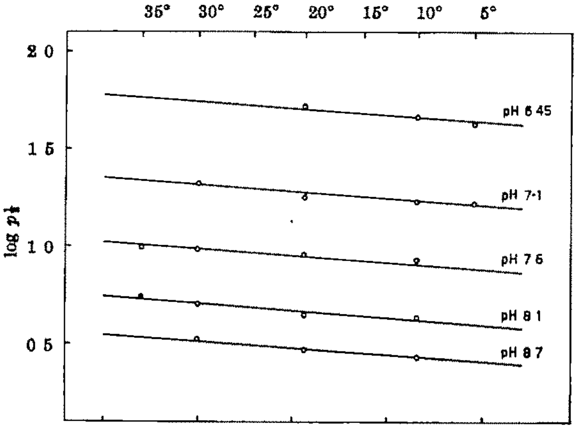

Fig. 2. Effect of temperature on the oxygen affinities of tuna hæmoglobin. Same conditions as in Fig. 1

parallel to the abscissa ; the oxygen affinity decreases on lowering the pH.

The changes in shape of the curve and in oxygen affinity are readily reversible over the entire pH range examined.

The effect of temperature on the oxygen equilibrium of tuna hæmoglobin has been studied at several pH values (Fig. 2). It was found that the temperature has very little effect on the oxygen affinity, at all the pH values examined. The shape of the oxygen dissociation curve did not change appreciably with temperatures.

The overall heat of the reaction :

$$\text{hæmoglobin} + O_{2(\text{gas})} \rightarrow \text{oxyhæmoglobin}$$

was calculated from the data for various pH-values[6] as $-1{\cdot}8$ kcal. mole^{-1} ; taking into account the heat of solution of oxygen, the heat of reaction would be nearly zero.

The results reported in the present communication show some important and characteristic differences between the oxygen equilibrium of the hæmoglobin of *Thunnus thynnus* as compared with that of mammalian hæmoglobin.

The effect of pH is to affect the oxygen affinity in the same direction as in mammalian hæmoglobin, but this is accompanied, in the case of the hæmoglobin of tuna by a great change in the shape of the oxygen dissociation curve. The inflexion of the curve is in this case a function of pH. In the case of mammalian hæmoglobin, differences in the shape at different pH's are observed only at very low or very high oxygen saturation[7] and do not affect the general shape of the curve.

The effect of temperature is even more unusual ; in the case of mammalian hæmoglobin the temperature has a great effect on the oxygen affinity, corresponding to an overall heat of reaction about equal to -13 kcal. mole^{-1} at pH 9·5[6]. On the other hand, the oxygen affinity of tuna hæmoglobin is practically unaffected by temperature.

The physiological meaning of these findings should be discussed in relation to the particular functional needs of the tuna fish ; for example, the insensitivity of the oxygen equilibrium of tuna hæmoglobin to changes in temperature could represent a sort of molecular adaptation which would enable the animal to live in waters of very different temperatures without modification of the functional properties of its respiratory pigment.

From a physico-chemical point of view, the study of hæmoglobin of lower vertebrates may represent a promising field for further knowledge of the kinetics and thermodynamics of the oxygen reactions of the respiratory proteins.

Oxygen Equilibrium of Myoglobin from *Thunnus thynnus*

MYOGLOBIN from several species of fishes has been recently purified and quite extensively studied[1–3], but no data on the oxygen equilibrium of these pigments have yet been reported.

In connexion with studies on the oxygen equilibrium of *Thunnus thynnus* hæmoglobin[4], it seemed of interest to examine the functional properties of myoglobin from the same animal.

Myoglobin was crystallized from the deep red muscles of the lateral line of an adult specimen of *Thunnus thynnus*. The absence of hæmoglobin from the preparation was checked by paper electrophoresis and spectrophotometry[3]. As previously reported[3], even crystalline preparations of tuna myoglobin are heterogeneous in electrophoresis for the presence of three myoglobin components, Mb I, Mb II and Mb III, which account respectively for about 80, 20 and 5 per cent of the total pigment. Such components have identical light-absorption spectra in the visible and Soret zone ; they are present also in the water extract of muscles. Owing to the small quantity of crystalline myoglobin of tuna available no separation of the different myoglobin components could be attempted, and the experiments have been performed with the total crystalline pigments.

In the case of human myoglobin no difference was noted in the oxygen equilibrium of the components Mb I and Mb II (ref. 5).

The reduction of ferrymyoglobin and the determination of the oxygen dissociation curves have been performed according to Rossi-Fanelli and Antonini[5].

Fig. 1 shows the oxygen dissociation curves of tuna myoglobin in 0·1 *M tris* buffer at pH 7·45. The curves obey the Hill equation :

$$y = \frac{K(pO_2)^n}{1 + K(pO_2)^n}$$

for a value of $n = 1$ (pO_2 = partial pressure of oxygen in mm. mercury). The oxygen affinity is high and very similar to that of mammalian myoglobins : at 20° C. the partial pressure of oxygen for 50 per cent oxygen saturation ($p\frac{1}{2}$) is 0·9 mm. mercury ; the value for human myoglobin in the

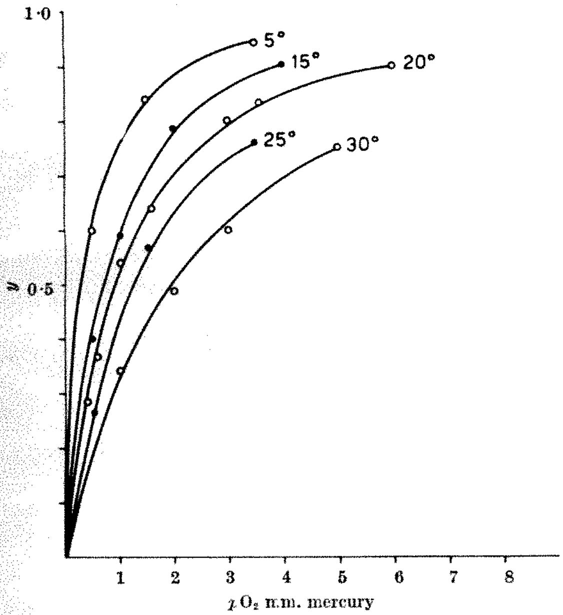

Fig. 1. Oxygen dissociation curves of tuna myoglobin at different temperatures: *tris*(hydroxymethyl)amino-methane buffer, ionic strength 0·1; pH 7·5; myoglobin concentration = 2×10^{-4} *M*; $y = \frac{(\text{MbO}_2)}{(\text{Mb}) + (\text{MbO}_2)}$

same conditions is 0·73 mm. mercury[5]. The effect of temperature on the oxygen affinity is also shown in Fig. 1; the overall heat of the reaction:

$$\text{myoglobin} + \text{oxygen} \rightarrow \text{oxymyoglobin}$$

calculated by the van't Hoff equation[6] between 5° and 30° C. was found to be $-13 \cdot 2$ kcal. mole^{-1}. The Bohr effect has been studied at 20° C. in 0·1 *M* tris buffers and was found, between pH 7·1 and 8·7, practically absent:

$$(\text{d} \log K)/(\text{d}p\text{H})_{20^\circ} = +0 \cdot 02$$

The results reported above show that tuna myoglobin has functional properties very similar to those of mammalian myoglobin: hyperbolic shape of the oxygen-dissociation curve, high oxygen affinity and absence of Bohr effect.

These results indicate that the functional and structural properties of the myoglobin do not change appreciably in animals belonging to different classes, and that this pigment has retained through all the species the same simple characteristic properties. On the contrary the blood hæmoglobin shows a greater structural complexity accompanied with a large functional variability according to the different biological needs of the various animal species.

RADIOBIOLOGY

Degradation of γ-Methyleneglutamic Acid by Plants

Many new amino-acids have been isolated from higher plants in recent years[1]. However, little is known concerning the function and metabolism of the majority of these acids. Frequently they have been considered to be rather akin to alkaloids; they are often found to be randomly distributed among the members of the plant kingdom, and yet they accumulate in large amounts in certain plants, sometimes being confined mainly to particular organs. These features suggest that a number of the acids are perhaps secondary products (by-products) of metabolism that can only slowly re-enter the main pathways of metabolism operative in plants.

γ-Methyleneglutamic acid and its amide, γ-methyleneglutamine, were among the first of the newer acids to be isolated[2]. The initial isolations were made from peanut plants; but now the substances are known to occur also in tulips[3], peas[4], hops[5] and bean seedlings[6]. Although γ-methyleneglutamic acid and γ-methyleneglutamine show the restricted distribution typical of the newer amino-acids, they are atypical from the metabolic point of view. The substances appear to be synthesized readily from carbon-14 labelled pyruvate, acetate, or glucose by cotyledon tissue of peanut seedlings, and the branched-chain carbon skeleton may arise by condensation of two pyruvate molecules[7]. Active preparations of a deamidase for γ-methyleneglutamine[8] and a transaminase utilizing γ-methyleneglutamic acid[9] have been obtained in extracts of peanut plants, while a decarboxylase capable of using γ-methyleneglutamic acid was present in tulip leaf extracts[10]. However, these *in vitro* reactions could be the result of non-specific action of glutaminase, glutamic–aspartic transaminase, and glutamic decarboxylase respectively, and they may inaccurately portray the true position regarding the degradation of γ-methyleneglutamic acid and γ-methyleneglutamine within intact plant tissues. The present experiments, which used carbon-14 labelled γ-methyleneglutamic acid, established with certainty that degradation of the acid occurs *in vivo*.

γ-Methyleneglutamic acid was synthesized by a procedure which introduced a carbon-14 label into the α-carbon atom. α-Iodomethylacrylic acid was synthesized from ethyl di(hydroxymethyl)malonate by the method of Welch[11], and this was esterified to give ethyl α-iodomethylacrylate. This ester was then condensed with ethyl [2-^{14}C] acetamidomalonate, following the method of Hellmann and Lingens[12], and subsequent hydrolysis of the condensation product with 6 *N* hydrochloric acid gave [α-^{14}C] γ-methyleneglutamic acid. By paper chromatographic methods, the acid was obtained radiochemically pure, when it had a specific activity of 1 mc./m*M*.

A solution of carbon-14 labelled γ-methyleneglutamic acid was supplied to shoot tips of peas (Carter's Little Marvel variety) and to immature peanut leaves through the cut ends of the shoots and petioles respectively. The labelled material was introduced into leaf disks of tulip by vacuum infiltration. In this way, each gram of fresh pea or peanut tissue received about 0·8 mgm. carbon-14 labelled γ-methyleneglutamic acid (5 μc.), while 0·3 mgm. carbon-14 labelled γ-methyleneglutamic acid (2 μc.) was introduced into each gram of tulip leaf disks. The plant tissues were then kept in continuous light

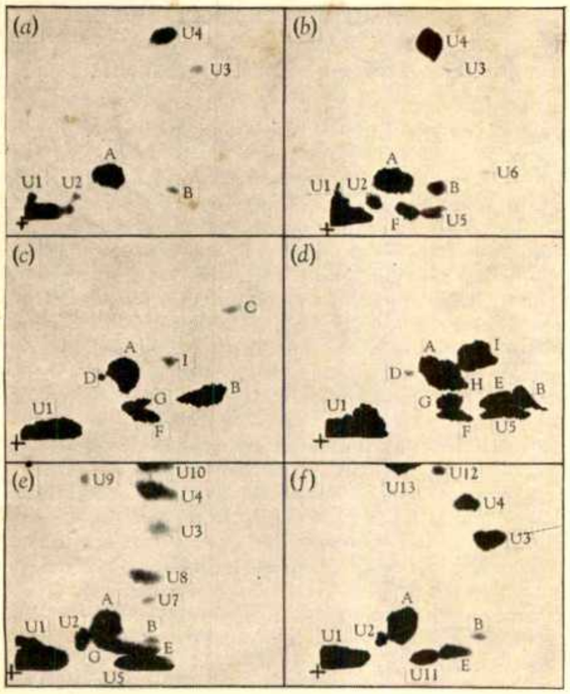

Fig. 1. Reproductions of radioautographs prepared from extracts of plants metabolizing [α-^{14}C] γ-methyleneglutamic acid. (*a*) Peanut leaves after 24 hr., and (*b*) after 48 hr. (*c*) Tulip leaves after 24 hr., and (*d*) after 48 hr. (*e*) Pea shoots after 24 hr., and (*f*) after 48 hr. The chromatograms were developed in phenol-ammonia (horizontal direction) and then *n*-butanol–acetic acid–water (vertical direction). The origin is marked +. Key to spots: *A*, γ-methyleneglutamic acid; *B*, γ-methyleneglutamine; *C*, γ-amino-α-methylenebutyric acid; *D*, glutamic acid; *E*, glutamine; *F*, asparagine; *G*, sucrose; *H*, glucose; *I*, fructose; *U*1, unknown radioactive substances probably including triose and hexose phosphates; *U*2–*U*13, other radioactive compounds of unknown identity

(900 ft.-candles) under humid conditions at 20°. After suitable time intervals, samples were killed by dropping into boiling 75 per cent (v/v) ethanol. After complete extraction of the aqueous-ethanol-soluble compounds, portions of the concentrated extracts equivalent to 50 mgm. of initial plant tissue were applied to two-dimensional paper chromatograms run in 75 per cent (w/w) phenol, followed by *n*-butanol–acetic acid–water (4 : 1 : 5). Radioautographs were prepared from each chromatogram and representative examples are reproduced in Fig. 1.

The radioautographs show that an extensive degradation of γ-methyleneglutamic acid occurred in all three species. Complete loss of the carbon-14 label from γ-methyleneglutamic acid could not be expected because the synthetic material was a DL-racemate.

Some products of γ-methyleneglutamic acid metabolism were common to pea, peanut, and tulip tissues; these included the labelled materials (designated *U*1) running near the origin on the paper chromatograms. This is the general area in which triose and hexose phosphates are encountered. The formation of glucose, fructose and sucrose was more marked in tulip leaves than in pea tissues: when peanut leaves were used, no activity could be detected in the simple sugars.

γ-Methyleneglutamine was labelled in all species at 24 and 48 hr. When the activity of the amide is expressed as a percentage of the activity present in the aqueous-ethanol-soluble fraction, this percentage is far higher for tulip leaves than for pea or peanut tissues. This observation is in agreement with previous findings. Pea shoots contain very small amounts of γ-methyleneglutamine, and therefore the rate of its synthesis may be expected to be low. The contrasting position found in tulip and pea leaves can be explained by the relative deamidase activities previously observed in extracts of these tissues; peanut leaves gave a very active enzyme preparation whereas negligible activity was associated with tulip leaf extracts[8]. A further relationship exists between the observations made in the enzymic and radioisotopic experiments. Labelling of γ-amino-α-methylenebutyric acid (the decarboxylation product of γ-methyleneglutamic acid) was observed only in tulip leaves. These leaves contain a powerful decarboxylase, but no γ-methyleneglutamic acid decarboxylation activity was detected in pea or peanut leaves[10].

The introduction of the carbon-14 label into glutamic acid, glutamine, and asparagine, in addition to sugars and sugar phosphates, suggests that at least a portion of the carbon skeleton of γ-methyleneglutamic acid, including the α-carbon atom, quickly enters intermediate metabolites associated with the reactions of the tricarboxylic acid cycle. However, the present preliminary results do not allow any detailed metabolic pathway for γ-methyleneglutamic acid degradation to be formulated.

Clearance Rates of Sodium-24, Potassium-42 and Iodine-131 in Normal Dog Hip Joints

A METHOD of assessing the vascularity of the femoral head using sodium-24 or iodine-131 clearance-rates has been previously described by Laing and Ferguson[1]. In a further study of osteoarthritis of the hip joint in the dog being conducted in this Laboratory it has become necessary not only to know the state of vascularity of the bone but also that of the joint itself, or more strictly, that of the synovial membrane.

The absorption of sodium-24 from the knee joint in humans has been studied by Jacox, Johnson and Koontz[2], and Harris and Millard[3]. Scholer, Lee and Polley[4] studied the clearance of sodium-22 and tritium from human knees. These workers estimated the arterial blood-levels of sodium-22 and tritium by a rather complicated method and deduced the clearance-rate for the joint. They found 70 per cent of the sodium-22 remained in the joint 20 min. after injection. The other two research groups and ourselves used an external counting method similar to that of Kety[5].

The present work was initiated in an attempt to discover the rates of clearance of substances of various molecular sizes from normal and abnormal joints, starting with simple salts and working up to layer organic molecules afterwards.

Sodium-24 and potassium-42 in the form of the labelled chlorides were obtained from Oak Ridge National Laboratory. The iodine-131 as sodium iodide was obtained from Squibb and Sons. All three are γ photon emitters. Sodium-24 with a half-life of 15·06 hr. emits γ photons of 1·368 MeV. and 2·753 MeV. and a β particle of 1·39 MeV. Potassium-42 with a half-life of 12·5 hr. emits γ photons of 1·5 MeV. and 0·32 MeV. and negative β particles of 3·5 and 2·0 MeV. Iodine-131 has a half-life of 8·05 days and emits negative β particles of 0·61, 0·25, 0·81 MeV. and γ photons with several peaks, the most important being at 0·36 MeV.

The fate of these isotopes following their injection into a joint can thus be easily followed by a surface-counting technique since they all emit suitable γ photons. For this purpose a columnar scintillation detector, with a half-inch thallium activated sodium iodide crystal, held in an adjustable detector arm (Tracerlab Model *SC* 52 No. 29) was used with a precision rate-meter (Atomic Accessories, Inc. *PCR* 105) and the results were recorded with a Texas instrument rectilinear recorder.

Fifty-seven adult dogs, including mongrels and pure bred of both sexes, were used in this study. Following injection of the radioisotope into a hip joint, a scintillation counter was then swung over the area and continuous recordings were made for 20 min. About 10–20 μc. of sodium-24 and potassium-42 and about 30 μc. of iodine-131 were injected to get suitable surface counts. Only one isotope was injected at any one time. Sodium-24 was injected into 29, potassium-24 into 24, and iodine-131 into 38 hip joints.

The results are presented in Fig. 1. The clearance rates for sodium-24 were 34·76 ± 6·33 per cent in 10 min., 57·06 ± 7·84 per cent in 20 min., for potassium-42, 46·95 ± 7·88 in 10 min. and 62·85 ± 8·59 per cent in 20 min., and for iodine-131, 56 ± 10·84 per cent in 10 min. and 75·15 ± 8·72 per cent in 20 min. Statistical analysis revealed no significant difference between the variances of the groups as calculated by the *F*-test, which is a measure of the dispersion of the values around the means. The means of the groups, however, differed significantly when examined by Fisher's *T*-test. At 10 min., the clearance of iodine-131 is significantly faster than that of potassium-42 ($P = 0{\cdot}0008$), which in turn is significantly faster than that of sodium-24 ($P = 0{\cdot}0001$). At 20 min., the clearance of iodine-131 is significantly faster than that of potassium-42 ($P = 0{\cdot}0001$), which is significantly faster than that of sodium-24 ($P = 0{\cdot}013$).

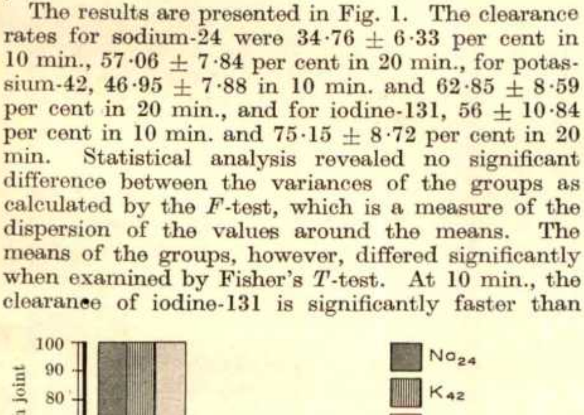

Fig. 1. Residual percentages of sodium-24, potassium-42 and iodine-131 remaining in normal dog hip joints after 10 and 20 min.

It is hoped that this work will form a basis for the study of clearance-rates in osteoarthritic and chemically and bacteriologically inflamed joints. Whether or not clearance is entirely by way of the synovial membrane or whether electrolytes also pass through the articular cartilage into the bone is not known. This question is to be examined by autoradiographic techniques. In addition, the fate of the β-emitting isotopes phosphorus-32, chlorine-36 and sulphur-35 injected into the hip joints of dogs is to be studied using needle Geiger–Müller probes.

BIOLOGY

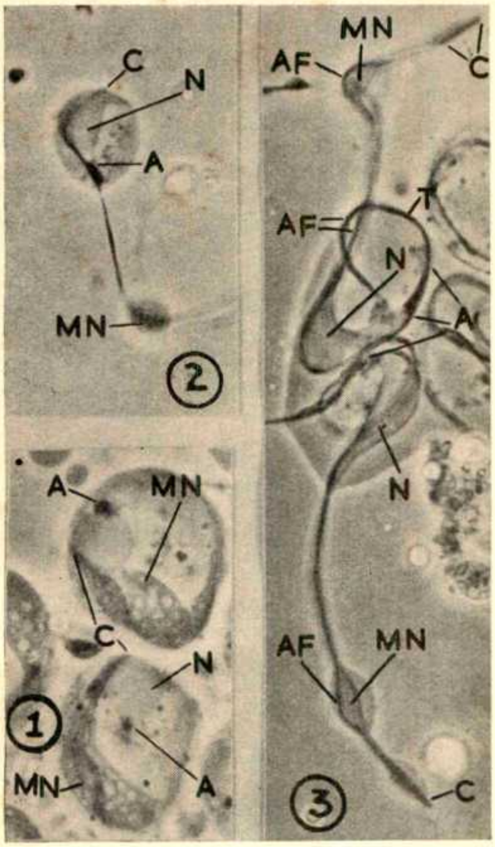
Position of the Proximal Centriole in Flagellate Spermatozoa

Gatenby and Mathur[1] have recently published a preliminary report on their investigations an the spermatogenesis of *Petrobius maritimus* (Thysanura; Machiloidea); but unfortunately they have made a number of sweeping generalizations which we cannot accept.

It is surprising that Gatenby and Mathur[1], while criticizing the work of Bowen[2] and Nath and Bhatia[3] on *Lepisma* sperm, have disowned the previous work of Gatenby and Mukerji[4], and Mukerji[5], who clearly supported Bowen[2] with regard to the anterior position of the centriole immediately behind a small structure considered by them as the acrosome. Indeed, these authors have gone to the extent of stating: "Thus we consider that in Fig. 7, after Bowen and Nath, the anterior bead (*C*) is not the centriole, but is the acrosome (whole or part). . .". They further state that the centriole remains in the neck region.

Gatenby and Mathur[1] quote, in support of their view, results obtained by electron microscopists with the sperms of mammals, molluscs, insects, oligochaetes and sea-urchins; but not one of these workers has worked on the sperm of *Lepisma*, *Cicindela*, *Lepas*, *Balanus*, schizopods, and *Bombinator*, quoted by Nath[6] as examples of sperms in which the centriole is situated at the anterior end of the sperm nucleus.

We have nothing to say about the findings of Gatenby and Mathur[1] on the spermiogenesis of *Petrobius maritimus* except (1) that this thysanuran belongs to the superfamily Machiloidea, whereas *Lepisma* belongs to the second superfamily of the order Thysanura, namely, Lepismatoidea; and (2) that the cytological phenomena in spermatogenesis of different families of the same group of animals are known to vary considerably, as in scorpions.



Figs. 1–3

When reviewing the previous work of Wilson and Nath on scorpion spermatogenesis, Nath emphasized[7] important differences in the behaviour of the mitochondria in the sperms of *Centrurus* and *Buthus* (fam. Buthidae) on one hand, and *Vejovis* (fam. Vejovidae) and *Palamnaeus* (fam. Scorpionidae) on the other.

We have recently carried out extensive phase-contrast and histochemical studies of the male germ cells of *Lepisma saccharina* and *Ctenolepisma urbana* (both belonging to the superfamily Lepismatoidea; subfamily Lepismatinae); and we fully confirm the previous findings of Bowen[2], and Nath and Bhatia[3] with regard to the position of the centriole at the anterior end of the nucleus and that of the acrosome in the neck region.

Fig. 1 shows two early spermatids of *Lepisma saccharina*. The nucleus (*N*) is still spherical; the acrosome (*A*) has been formed at the posterior end of the nucleus; and the centriole (*C*) is at the anterior end, giving rise to the axial filament surrounded by the two clearly defined halves of the elongating mitochondrial *Nebenkern* (*MN*). In Fig. 2 the nucleus (*N*) has become beak-shaped; the centriole (*C*) is just behind the anterior beak of the nucleus, giving off the very much attenuated tail passing by the side of the nucleus (*N*) and the acrosome (*A*). In Fig. 3 the centriole (*C*) has become rod-like and has moved far forward, dragging behind it the axial filament (*AF*) surrounded by the very much attenuated mitochondrial *Nebenkern* (*MN*); the nucleus (*N*) is bent on itself; and the acrosome (*A*) in the neck region has become funnel-shaped.

We wish to emphasize that: (1) the rod-like structure at the anterior end of the maturing sperm is the centriole, since it gives off posteriorly the axial filament and the mitochondrial *Nebenkern*, and also it is completely negative to periodic acid–Schiff reagent; and (2) the funnel-shaped structure in the neck region of the sperm is the acrosome, since it arises from the acroblasts and is positive to the periodic acid–Schiff reagent[8].

Finally, we confirm[2] that the mitochondrial *Nebenkern* is of the typical insect type, forming the tail sheath of the sperm.

We do not see anything in the *Lepisma* light microscope photomicrographs of Dr. Nath and his collaborators which either lead us to consider that his (*C*) in Fig. 2 is a centriole and not an acrosome, and his (*A*) is not a centriole plus the large insect centriole adjunct, or which persuades us that these two thysanurans could possess spermatozoa fundamentally different.

As to possible fundamental cellular variations in closely allied animals, the grouping of mitochondria in various scorpion spermiogeneses refers to growth and maturation divisions chiefly, but in all these animals where the spermiogenesis is known, the acrosome is anterior, and the centriole posterior, in the nucleus. Dr. Nath *et al.* state that it is surprising that we disowned some of the previous work of Mukerji and Gatenby. The point here is the question of the nature of the longitudinal line (their *AF*) on the nucleus. At one time it was thought (by J. B. G.) to be a part of the flagellum, but recently in *Lumbricus*, Gatenby and Dalton[1] found a similar line by electron microscopy which is not flagellar, and this has thrown doubt on the previous identification in *Lepisma*. This doubt has been strengthened by the discovery that the anterior centriole (*C*) in several Orthoptera and in *Dytiscus* lies within the cushion-shaped centriole adjunct (*CA*) as in the micrograph reproduced here (Fig. 1). Dr. Nath comments that it is surprising that electron microscopists have not studied *Lepisma*, *Lepas*, schizopods, and *Bombinator*. Not really, because the conventional light-microscope 5-μ section using Fleming with acetic-Heidenhain is easy, quick, and cheap to make: our sole chance recently to get micrographs of *Petrobius* resulted in a failure. In any event, referring to *Bombinator*, M. Burgos and Don Fawcett[3] studied another toad (*B. arenarum*) and found the two centrioles post-nuclear, and only the acrosome at the sperm tip.

Now as regards the clear microphotographs shown by Dr. Nath *et al.*, we all agree that their lettering in Fig. 1 is correct. But by Fig. 2, the acrosome has thinned out and become pointed, the adnuclear

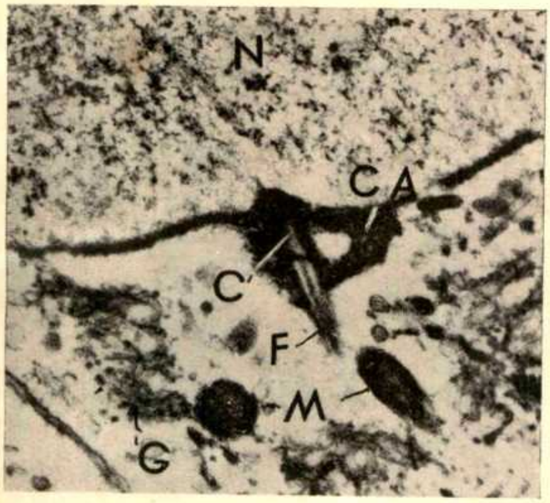

Fig. 1. Micrograph at × 24,000 of part of spermatid of *Pachyrhamma fiasifer*, showing nucleus (*N*), centriole (*C*) embedded in centriole adjunct (*CA*), flagellum (*F*), heads of mitochondrial *Nebenkern* (*M*). (Photograph by W. S. Bertaud, Dominion Physical Laboratory, New Zealand. By kind permission of the Director)

thread has developed, and the centriole adjunct (*A*) has grown quickly, as has been shown to be the case in *Nemobius* by Gatenby and Tahmisian[3]. The long body (*C*) in their Fig. 3 is the acrosome, the dark edge (*AF*) the adnuclear thread, and below it some sort of modification of the body (*A*) in their Fig. 2. The orientation of the cells is correct, the acrosome being anterior in all figures, except the lower spermatid in Fig. 1.

As regards the periodic acid–Schiff, formalin-fixed material of *Petrobius*, we have not succeeded in such small cells in getting useful preparations and are unable at present to comment on evidence arising from this method.

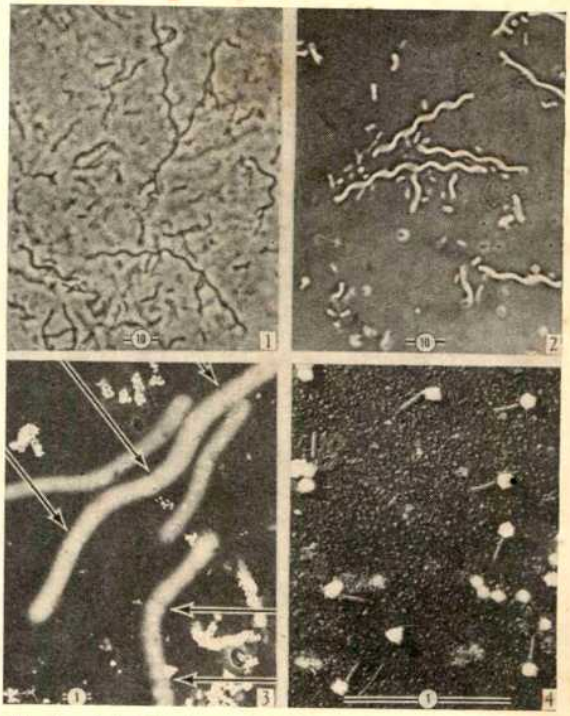
A *Spirochaeta* Phage

A micro-organism identified provisionally as *Spirochaeta rosea* nom. prov. has been isolated from a marine upper littoral rock-pool at Woods Hole, Mass. The filaments are spiral, 5–200μ long, 0·7μ wide, with a regular pitch of about 7μ and an amplitude of 2μ (Figs. 1 and 2). Transverse cell walls, approximately 2·5μ apart, are revealed by phase-contrast or electron microscopy (Fig. 3). In size and form the organism resembles *S. plicatilis* Ehrbg. (= *Ehrenbergia plicatilis* (Ehrbg.) Gieszczykiewicz)[1–4], but in mass the cells are seen to be pinkish or brick red. Growth is markedly aerophilic, with an optimum temperature of 35° C. In sea water supplemented with yeast extract (0·5 per cent) and tryptone (0·5 per cent), the doubling time is 100–120 min. At concentrations less than one-half sea water, growth is suppressed.

The mode of movement of the filaments, a slow creeping over solid substrata, accompanied by bending, undulation and rotation, recalls that of filamentous Cyanophyceae (cf. *Spirulina*, in which non-chlorophyllous species have been described). These features, and the relatively large size of the organism, distinguish *Spirochaeta* from parasitic spirochaetes of the Microspirochaetaceae[3]. The pigments, which can be readily extracted with organic solvents and separated on paper chromatograms, comprise a small amount of carotene and one or more xanthophylls. The predominant pigment exhibits absorption maxima at 448, 474 and 506 mμ in 95 per cent ethanol, and 454, 483 and 515 mμ in chloroform. These peaks agree closely with those of myxoxanthophyll[5], providing additional evidence for cyanophycean affinities.



Figs. 1 and 2. *Spirochaeta rosea* (phase contrast : J. W. Watson).
Fig. 3. *Spirochaeta rosea* (electron micrograph : D. E. Philpott).
Fig. 4. Particles of phage (electron micrograph : D. E. Philpott).
(Scales in μ)

An enrichment mixture of *S. rosea* with marine mud from the Eel Pond, Woods Hole, was left at room temperature for a few days. A portion of the supernatant sea water was then shaken with chloroform to kill bacteria, and sampled in a dilution series in poured plates containing nutrient medium, 0·7 per cent agar, and a liberal inoculum of *S. rosea*. Clear plaques, 4 mm. in diameter, appeared within 24 hr., and indicated a concentration of about 500 phage particles per millilitre of original suspension. From these, pure phage strains were isolated by routine subculture procedures. Titres of 10^{10}–10^{11}/ml. were readily obtained. Virulence was not reduced by incubation in distilled water at 23° C. for 24 hr.

The phage particles from an infected culture were concentrated by centrifugation at 2,800*g* for 45 min., washed, dried in air, shadowed with chromium, and examined by electron microscopy. They appeared similar to those of the *T*-2 series of coli-phages, with a polyhedral 'head' 90 mμ in diameter, a 'neck' 15 mμ long, and a 'tail' 140 mμ long and 25 mμ wide (Fig. 4).

Though the taxonomic position of *Spirochaeta* remains uncertain, it may be regarded as a non-photosynthetic member of the blue-green algae. The only previous record of a virus infecting an alga is a preliminary report of an agent causing lysis in *Chlorella* cultures[6]. The immediate interest of phycophages arises from the possibility that they may resemble the viruses of angiosperms in containing ribonucleic acid. Though the *Spirochaeta* phage described here superficially resembles the bacteriophages containing deoxyribonucleic acid, its nucleotides will be investigated.

Ethylene Production by Tomato and Apple Fruits

The development of the flame ionization detector for gas chromatography has made it possible to investigate in detail the production of ethylene by tissue slices and mitochondria from fruits. We have constructed a gas chromatograph for this purpose following the design of Meigh[1]; but by modifying certain details the sensitivity has been increased some tenfold, making it possible to detect 0·03 µl. of ethylene per litre of air in a 1-ml. gas sample. The improved sensitivity can be attributed largely to the amplifier and to the use of a stationary phase having very low volatility.

The detecting system consisted of a single flame ionization detector constructed (Fig. 1) in the simplest possible manner. Air to support combustion was filtered and supplied at a rate of 30 l./hr. from a cylinder fitted with the usual type of pressure-reducing valve. The detector output was amplified by a vibrating reed electrometer (Applied Physics Corp., model 31), using the 10^8 ohm input resistance. The output was recorded on a galvanometer recorder. The eluent gas was a 1 : 1 mixture (v/v) of nitrogen and hydrogen taken from a cylinder fitted with the usual type of pressure-reducing valve, which was used to control the column input pressure at 36·3 cm. mercury above atmospheric. The column, which was kept at about 22° by immersing it in an unheated water bath, was 5-mm. bore, length 5·5 m., packed with Johns Manville *C*22 firebrick 60–80 mesh-range, impregnated with silicone oil 550 in the ratio 100 : 30 by weight. The column, after packing, was heated to 100° and flushed continuously with nitrogen for several days. This reduced to a minimum the background caused by volatile impurities evolved by the stationary phase.

This system was used to determine the evolution of ethylene by whole fruit, fruit segments, tissue slices, homogenates, mitochondria, microsomes and supernatant fractions from apple and tomato fruit. Results from these studies indicated that the evolution of ethylene by tomatoes is greatly stimulated by cutting the fruit into segments and tissue slices. On the other hand, ethylene evolution by apples was not greatly changed by this treatment (Table 1).

Maceration of the tissues caused a very considerable decline in ethylene evolution in both the apple and tomato fruit. The mitochondria and microsomes isolated from these homogenates evolved a negligible amount of ethylene.

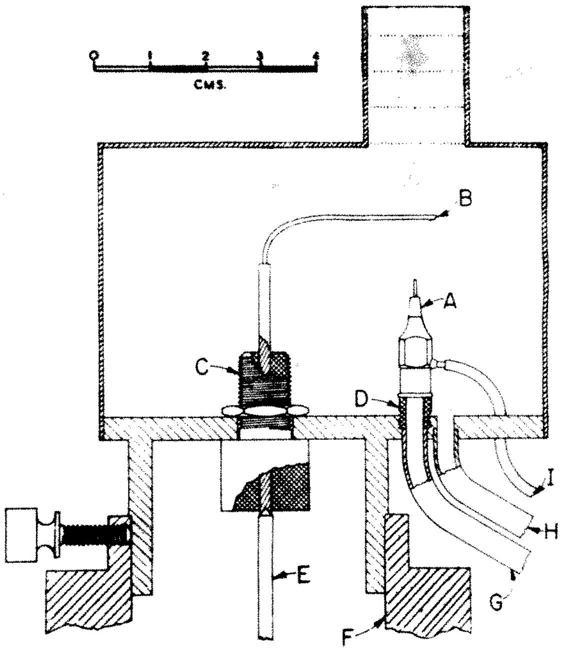

Fig. 1. Diagram of flame ionization detector. *A*, Hypodermic needle No. 22; *B*, collector electrode, 3 mm. loop of No. 23 nichrome wire; *C* and *D*, 'Teflon' insulators; *E*, electrometer input; *F*, electrometer shield; *G*, column connexion; *H*, air inlet; *I*, polarizing voltage, 90 V. positive

Although Spencer[2] identified ethylene in emanations from mitochondrial preparations from tomato fruit, and Burg and Thimann[3] implicated cytoplasmic particles as the source of ethylene production in apples, we could not detect significant amounts of ethylene in mitochondrial or microsomal systems derived from apples or tomatoes. It is especially significant that the apple mitochondria in these studies were able to oxidize Krebs cycle intermediates and could carry out oxidative phosphorylation[4].

It must be concluded from these results that the biosynthesis of ethylene is not directly associated with Krebs cycle organic acid metabolism. Burg[5] reached a similar conclusion from studies in which

Table 1. ETHYLENE PRODUCTION BY WHOLE FRUIT, SEGMENTS, SLICES, HOMOGENATES AND SUBCELLULAR PARTICLES OF APPLES AND TOMATOES

	µl. ethylene/hr./kgm. at 30° C.						
Fruit	Whole	Segments	Tissue slices	Homogenate	Mitochondria	Microsomes	Supernatant
Apples	29·6	35·4	20·3	6·8	<0·003	<0·003	<0·03
Tomato (ripe)	4·4	58·6	102·0	2·2	<0·003	<0·003	<0·03

Measurements were made after the ethylene had accumulated for 2–4 hr. from the apple tissue and 4–6 hr. from the tomato tissue.

The whole fruit was cut into 16 equal segments. Only pericarp wall tissue was used from tomato segments.

Apple slices were disks 1 cm. in diameter and 2 mm. thick. Tomato slices were 4-mm. cubes of the pericarp wall. Both were floated in 0·4 *M* sucrose.

Homogenates were prepared at 2–4° C. by blending in a Waring blendor for 2 min. at reduced speed in 0·2 *M* *tris* buffer, 0·25 *M* sucrose, 0·01 *M* ethylenediamine tetraacetic acid and 0·01 *M* ascorbate. The *p*H of the homogenates was 8·4.

The mitochondria were incubated in a medium containing 3 m.moles adenosine triphosphate, 10 m.moles glucose, 60 m.moles phosphate, 20 m.moles magnesium, 30 m.moles malate, 10 m.moles sucrose, 2 mgm. yeast concentrate and 2 mgm. bovine serum albumin.

The microsomes were isolated at 100,000*g* in the No. 30 rotor of the 'Spinco' preparative ultracentrifuge and incubated in the same reaction mixture as the mitochondria.

apples were treated with sucrose and acetate labelled with carbon-14.

Is *Nectria haematococca* Berk. and Br. the Perfect Stage of *Fusarium oxysporum* Schl. forma *pisi* (Lindf.) S. and H.?

In a recent communication[1], Dr. E. W. Buxton reported the discovery of mature perithecia in a nutritionally deficient mutant isolate of *Fusarium oxysporum* Schl. forma *pisi* (Lindf.) S. and H. after ultra-violet irradiation. These perithecia were shown to be the perfect stage of this particular isolate and were identified as *Nectria haematococca* Berk. and Br. (=*Hypomyces solani* Rke. and Berth. emend. S. and H.).

As *Nectria haematococca*[2,3] has long been known to be the perfect stage of another species of *Fusarium*, namely, *F. solani* (Mart.) App. and Wr. emend. S. and H., classified in the section Martiella, I was surprised to learn that this same *Nectria* sp. had been found to be the perfect stage of *F. oxysporum* f. *pisi*, classified in the section Elegans. Furthermore, this phenomenon was quite unexpected as it has always been assumed by *Fusarium* taxonomists that, should a perfect stage be formed by a representative of the section Elegans, it would be a *Gibberella* sp. This assumption is based on the fact that the perfect stage characteristic of each of the sections, Lateritium and Liseola, which are most closely related to the section Elegans, is a *Gibberella*.

As isolates of *Fusarium* species that form their perfect stage in culture have been of particular interest to me for several years, duplicate subcultures of the homothallic isolate of *F. oxysporum* f. *pisi*, in which mature perithecia of *Nectria haematococca* were found by Dr. Buxton, were obtained for the purpose of observation and study from the Commonwealth Mycological Institute, Kew, England, through the courtesy of Dr. C. Booth. When they were received by me they appeared to be identical and in each of them the red perithecia characteristic of *Nectria haematococca* could be distinguished readily.

I followed my usual procedure in examining and identifying isolates of *Fusarium*[4]. Several transfers, using the mass culture method, were made from one of the sub-cultures to slants of potato sucrose agar. Numerous monosporous cultures were established by transferring single macroconidia of the *Fusarium* stage present in one of the sub-cultures as received, and others by transferring single ascospores taken from the mature perithecia of *Nectria haematococca* present in the sub-culture. After these various cultures had been kept at room temperature in the laboratory for about ten days, they were examined macroscopically and microscopically and all were identified as *F. solani*, not as *F. oxysporum*.

Hildreth[5] reported recently that he sometimes found it difficult to distinguish between certain isolates of *F. oxysporum* f. *pisi* race 2 and *F. solani* f. *pisi*. Close similarities in the virulence and development of symptoms exhibited by these two species of *Fusarium* were evident to him. For example, *F. solani* f. *pisi* invaded the upper stem of the pea plant with vascular penetration resembling that accomplished by *F. oxysporum* f. *pisi* race 2. Similarly, *F. oxysporum* f. *pisi* produced a root rot accompanied by severe cortical decay in certain varieties of peas identical with that effected by *F. solani* f. *pisi*.

It is my opinion that the culture in which perithecia of *Nectria haematococca* were found by Dr. Buxton, is an isolate of *F. solani* f. *pisi* (Jones) S. and H. that is apparently capable of vascular penetration similar to that produced by *F. oxysporum* f. *pisi*. As the perfect stage of *F. solani* f. *pisi* has not been known previously, its occurrence has been reported for the first time by Dr. Buxton.

CYTOLOGY

Nuclear Phenomena in *Trametes cingulata* Berk.

Initiation of dikaryophase has been studied in considerable detail by a number of workers[1] on various species of hymenomycete. I have studied the nuclear phenomena in the life-history of *Trametes cingulata* Berk.

For the study of the nuclear conditions in the basidia, small rectangular pieces (5 mm. × 5 mm.) of fresh fruit bodies of *T. cingulata* with well-developed pore-tubes were fixed while growing on the living host in Nature. Different killing and fixing reagents were tried. Of these, the Bouin–Allen fixative gave the most suitable preparations. The materials were fixed in two lots and during different intervals of time, one between 12.30 and 2.30 p.m. and the other between 12 and 1 a.m. Washing, dehydration and embedding were done by following the standard schedule. Sections of 8–10μ in thickness were cut and were found to be suitable for observations. Of the stains, Heidenhain's iron–hæmatoxylin gave the most satisfactory result. Nuclear conditions in spores, germinating spores and in the primary and secondary mycelia were studied from whole preparations on slides, following Kniep's[2] agar-film technique.

A mature basidium is always found to be tetrasterigmatic, quadrisporous and broadly clavate in shape. The young basidia, on the other hand, show all stages of transition from slightly inflated terminal hyphal cells to broadly clavate mature ones. At the beginning, they are always binucleate and the two small unpaired nuclei are found lying one above another and at a little distance apart (Fig. 1*a*). Each nucleus is of the homogeneous unexpanded type, as defined by Pinto-Lopes[3], and in each its chromatin and nucleolus are contracted into an intensely stained homogeneous body. However, this conjugate pair of nuclei within the young basidium soon fuse and a synkaryon is formed which moves to the upper part of the basidium. The structure of the large and prominent fusion nucleus at the resting stage consisted of a deeply stained nucleolus and several deeply stained heterochromatin bodies on a feebly stained chromatin reticulum.

Karyogamy was soon followed by two successive divisions together constituting a meiotic phase at the end of which four daughter nuclei are formed. Six chromosomes can be seen to pass to each pole of the spindle in the anaphase stage of the first division, so that the haploid number of chromosomes in *T. cingulata* is six ($n = 6$). This is further corroborated by the presence of the same number of chromosomes in the metaphase and anaphase stages during the second division of the daughter nuclei. The orientation of the spindle within the basidium is not definite in all cases. The four daughter nuclei are conspicuous and are of homogeneous and unexpanded type. Four sterigmata appear at the apex of the basidium while it is in the quadrinucleate stage. When fully developed, the tips of the sterigmata become gradually swollen, and finally a spore is formed at the apex of each sterigma. After nuclear migration, the basidia become empty and appear somewhat collapsed.

The spores of *T. cingulata* are unicellular, uninucleate, apiculate, hyaline and without any evident endospore. The nucleus is situated almost at the centre of the spore, and shows itself as a large deeply stained body when stained with iron–hæmatoxylin. During germination, when the germ-tube is formed, the nucleus of the spore divides and either one or both the nuclei migrate immediately into the germ-tube (Fig. 2*e*). After this migration the first cross-septum is laid down at the base of the germ-tube. As the germ-tube elongates, it branches, and due to irregular formation of septa, uni-, bi-, or multinucleate hyphal cells make their appearance. In later stages, the hyphal cells appear mostly monokaryotic.

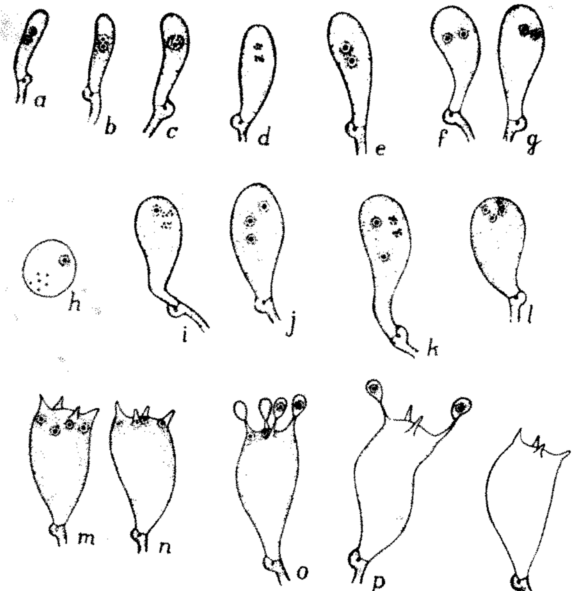

Fig. 1. Nuclear phenomena in the basidium and the development of basidiospores; *a*, *b*, young basidia each with a dikaryon; *c*, formation of synkaryon; *d*–*l*, two divisions of synkaryon forming a meiotic phase (*h*, a polar view of second metaphase division from the top of the basidium; *i* and *k*, anaphasic spindle of second division showing six chromosomes at each pole); *m*–*p*, successive stages in the development of sterigmata and basidiospores; *q*, an old basidium after discharge of basidiospores

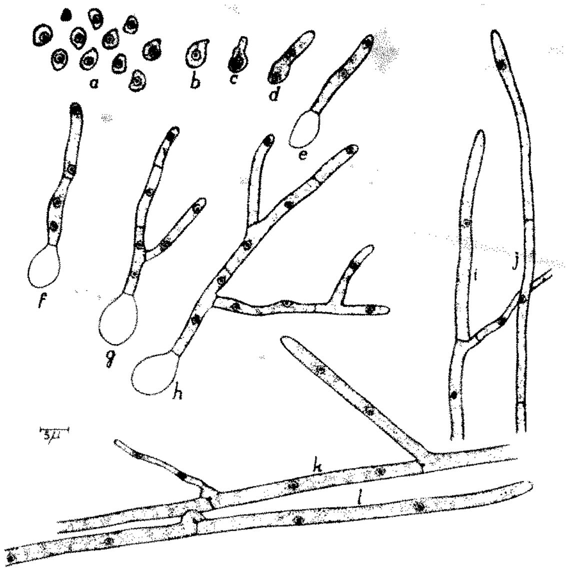

Fig. 2. Nuclear phenomena in basidiospores, spore germination and in the primary and secondary mycelia; *a*, basidiospores; *b*–*j*, successive stages of germination of basidiospores and formation of primary mycelium; *k*–*l*, some secondary hyphæ with clamp connexions and a dikaryon in each cell

In stained preparations of secondary mycelium, it is found that most of the hyphal cells are dikaryotic, but rarely a cell with two to four nuclei can be found. Clamp-connexions are found at most septa. The nuclei in the spores, germinating spores and the primary and secondary mycelia are found to belong to the 'homogeneous type'. Division stages of the vegetative nuclei, however, have not been observed.

I am grateful to Dr. S. N. Banerjee, Department of Botany, University of Calcutta, for his helpful advice in connexion with the present investigations.

A Simplified Method for the Study of Chromosomes in Man

GREAT advances in cytogenetics resulted from the use of the Feulgen 'squash' technique after pretreatment of cells with hypotonic solutions and colchicine. The cells are submitted to the action of colchicine chiefly to inhibit spindle formation, thus causing accumulation of metaphases and dispersal of chromosomes in the cytoplasm; in addition, the drug has the valuable effect of shortening the chromosomes and inducing sister chromatids to diverge, thus making clear the position of the centromeres. In this way, the whole character of the chromosome is easily and quickly recognizable. For these reasons colchicine is widely employed in plant and animal cytogenetics.

In man, however, tissue culture seems to be an obligatory step in the technique. Colchicine is added to the culture to obtain the desired effects on cells in mitosis. Tissue cultures, however, take time to prepare and demand technical conditions not always accessible to general laboratories. Moreover, alterations of chromosome pattern have been ascribed as due to culture procedures.

Searching for a simplified technique, we tried to submit human cells *in vivo* to the action of a derivative of colchicine and thus to avoid the inconvenience of tissue culture. We used desacetylmethylcolchicine ('Colcemid' or 'Demecolcine', Ciba), which has the same effects as colchicine, but is twenty to thirty times less toxic[1]. Initially, the drug was used in humans with malignant diseases and afterwards in normal humans and in other clinical conditions.

After preliminary trials, we chose a dose of 0·1 mgm./kgm. body-weight, diluted in saline and slowly administered intravenously. This amount is much less than those used in the therapy of gout and neoplastic disease in man[1] and in animal experiments.

The drug was allowed to act in the organism for 2 hr. and then bone marrow was obtained by sternal puncture. The marrow specimen was converted into a suspension of cells, treated with a hypotonic solution, filtered through a special sieve and stained with Feulgen reagent, according to the technique described by Ford and Hamerton[2]. After squashing, the preparations were sealed with hard paraffin and observed under an oil-immersion lens. The cells of eight individuals were studied in this way.

The preparations showed a satisfactory number of cells in mitotic metaphase, with good spreading of chromosomes which disclosed the characteristic effects of the drug (Fig. 1). Counting, sex identification and the study of individual chromosomes could be easily carried out. To avoid breaking the cells, no attempts were made to obtain permanent preparations. No departure from the normal number of chromosomes was observed in normal cases, except for the polyploid cells occasionally seen in bone marrow.

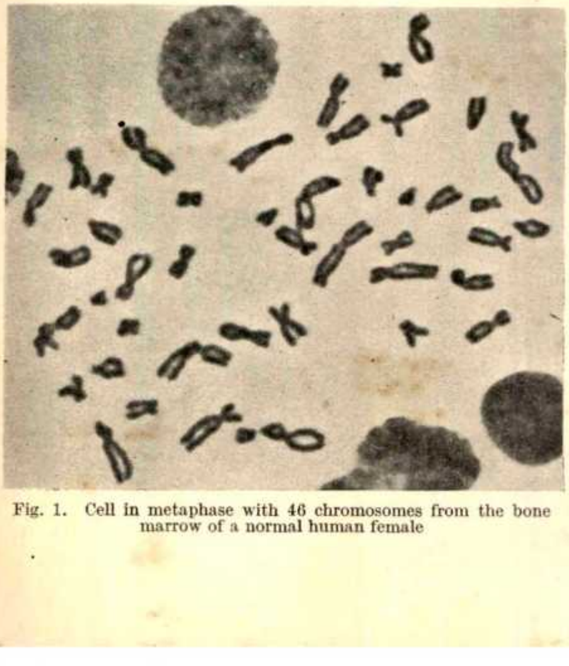

Fig. 1. Cell in metaphase with 46 chromosomes from the bone marrow of a normal human female

The simplicity of the method led us to use it in three patients for the study of the chromosomes of malignant cells in ascitic and pleural fluids. The same dose of the drug was injected into abdominal or pleural cavities. The fluids were obtained 2 hr. afterwards and, after spinning, the cells were treated by the same technique. The results were identical with those observed for bone marrow cells. Qualitative and quantitative data obtained with this method will be reported elsewhere.

All individuals were followed clinically and hæmatologically and no abnormality was detected that could suggest toxic effects of the drug.

We believe this method will be useful for chromosomal studies in other human tissues, whether neoplastic or not. These results were described at the fourth meeting of the Sociedade de Biologia de Ribeirão Prêto on November 11, 1959.

Blocking of Mitosis by Heat Shock

When eggs of *Trichogaster trichopterus* var. *sumatranus* (Teleostei: Anabantidae) are subjected to + 39/40° C. for 3–6 min., mitosis is temporarily halted, being resumed immediately once the eggs are brought back to normal temperature (+ 27° C.). At temperatures of 40·5/42° C. for 3–7 min. mitosis is halted, while the mitotic structures are changed to an extent which necessitates a re-organization after the termination of the heat shock before mitosis can be resumed. At still higher temperatures similar changes are invoked by the heat treatment, but with increasing temperatures the eggs rapidly lose the property of post-blocking restitution.

The present communication is concerned with the blocking of different mitotic stages in the first and second cleavage divisions in *Trichogaster* using heat shocks of + 40·5/42° C. for 30 sec.–7 min. as the blocking agent. The material of 240 heat-treated eggs was fixed (together with untreated controls) in *Kahle* without water (96 per cent ethanol, 15 parts; 40 per cent formaldehyde, 6 parts; glacial acetic acid, 1 part), and 10-μ serial sections were stained with Heidenhain's hæmatoxylin.

The changes invoked by the heat shock are as follow:

Prophase (Fig. 1). The nucleus shows a shrunken appearance, and the nuclear membrane may have broken down. In the latter case the chromosomes are found close together, suggesting that the breakdown has been preceded by nuclear shrinkage. In most cases the centrioles have approached one another. The asters have been temporarily reduced in size and appear generally as a monaster.

Prometaphase (Fig. 2). The chromosomes appear largely unchanged, having retained the condensed state of prometaphase. The position differs from that of normal prometaphase in that the chromosomes are found outside the original spindle field in the

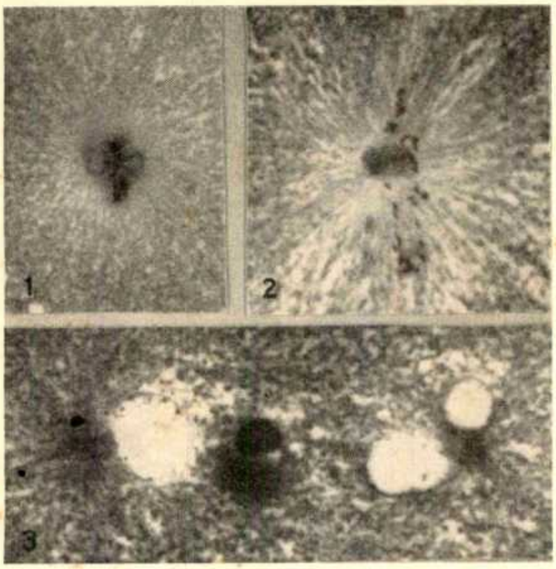

Fig. 1. Second prophase blocked by heat shock and fixed upon termination of the treatment. Mitotic axis approximately as in Fig. 3. × 1,000
Fig. 2. First prometaphase blocked by heat shock and fixed 1½ min. after the termination of the treatment. Mitotic axis approximately as in Fig. 3. × 1,000
Fig. 3. First anaphase blocked by heat shock and fixed upon termination of the treatment. (The dark bodies between the nuclei are yolk granules.) × 1,000

plane of the metaphase plate. The centrioles have approached one another. The asters have been temporarily reduced in size; they appear as a monaster when they rapidly resume their normal size after the termination of the heat shock. The spindle is rapidly disorganized as a visible structure.

Metaphase. The chromosomes appear unchanged. The centrioles have retained their normal distance from one another, giving rise to an amphi-aster mitotic apparatus without a visible spindle after the heat treatment has terminated.

Anaphase (Fig. 3). The chromosomes undergo vesiculation in the course of the treatment, changing into telophase nuclei or tight groups of chromosomal vesicles. In cases interpreted as early anaphase, where the separation of the chromosomes had not been completed, one vesicular nucleus is found in the position of the metaphase plate. In later anaphase the chromosomal vesicles or the two nuclei are found close to each of the centrioles. The migration of the centrioles has been halted, but not reversed. The asters are rapidly reduced in definition. The spindle loses rapidly in definition, and the interzonal part appears to become disorganized before the half-spindles contract, bringing the chromosomes close to the centrioles.

Telophase. The features are similar to those found after blocking in late anaphase. In some cases, however, the nuclei have the same shrunken appearance as have nuclei treated in prophase.

None of the changes described above was found in the untreated controls.

The action of heat shock on the cell centre and the nuclear structures seems to be as follows. While the migration of the centrioles is halted in all mitotic stages, it is reversed in prophase and prometaphase. Prior to anaphase, the asters are able to resume their cycle of size increase once the heat shock is terminated. If anaphase has commenced, new asters are not formed until after the lapse of some minutes. In the nuclear cycle of condensation and extension[1], the process of the mitotic stage concerned appears to proceed during the heat shock, while the switch from condensation to extension at the onset of anaphase does not take place during heat treatment. The switch in the nuclear cycle in the transition from telophase to prophase appears also to be inhibited. (The shrinkage found in some telophase nuclei may indicate that the nuclear transition to prophase has already commenced before any morphological changes can be identified. In the present material the processes of the first- and second-cleavage divisions overlap to a considerable extent (unpublished work).)

It appears then that the mode of response to heat shock varies during the mitotic cycle, and the changes in the mode of response—which cannot be explained by the methods employed in the present investigation—appear to take place simultaneously with the change in the number of organizing structures, that is, centrioles and centromeres.

GENETICS

'Sage': a Colour Modifier in *Aspergillus nidulans*

Conidia of wild-type *Aspergillus nidulans* are green, but mutants occur with yellow and white spores. The genetical basis for these colour differences has been shown by Pontecorvo[1] to be due to two unlinked genes; one, *Y*, controlling spore colour and giving green spores, its mutant form *y* being yellow, and the other, *W*, controlling presence or absence of spore colour. The mutant form of this gene, *w*, produces a white phenotype whether *Y* or *y* is present. We have confirmed this with our material.

While irradiating a green-spored, biotin-requiring strain (*W Ybi*) with ultra-violet light, a pale green, biotin-requiring mutant was isolated, which is clearly distinct from the colours hitherto described. In a cross with yellow (*y BI*) this pale green mutant gave progeny of four classes of spore colour in equal proportions: normal green and normal yellow together with pale green and a pale yellow spored class. It would seem that the pale yellow and pale green strains carry the mutant gene. This mutant modifies both yellow and green pigments and the four classes indicate that the mutation has occurred at a gene locus not linked with *Y*. We have called this mutant 'Sage', its symbol being *sa* and that of the non-mutant allele *SA*.

In order to test this idea a further cross was made using the pale yellow of presumed genotype (*W*) *sa y* (*BI*) and a white-spored strain which is known to carry *Y* and requires biotin for growth. Biotin and *Y* are linked by 5–7 units of recombination. The results are given in Table 1.

From these results it can be concluded that: (1) the expression of the phenotypes *sa Y* and *sa y* is

Table 1. Cross : *W sa yBI* × *w SA Ybi*

Colours	White	Pale yellow	Pale green	Yellow	Green
Frequency	554	186	146	91	81

Colour	Biotin requiring	Biotin independent	Total
Pale yellow	9	117	126
Pale green	121	7	128
Yellow	6	74	80
Green	56	7	63

dependent on the presence of the non-mutant allele at the *W* locus (whites 554 : colours 504). (2) *SA* and *Y* segregate independently. (3) *SA* is linked with white (*W*). This is apparent from the following :

Parental classes	*W sa*	332	34 per cent recombination
Recombinant classes	*W SA*	172	

Two other classes, *w SA* and *w sa*, occur, but are white spored and cannot be used in the analysis. (4) *SA* and *BI* segregate independently.

It is clear that at least three genes control the formation of conidial pigment in *Aspergillus*.

The change brought about by the mutation at the *SA* locus has been studied by extracting pigment from the pale yellow spores and comparing it with pigment obtained from normal yellow spores. The method used depends on the acidic nature of the pigment and it is extracted presumably as the sodium salt. Acidification of the solution of this salt in dilute aqueous sodium hydroxide with dilute hydrochloric acid results in precipitation of the pigment, and it is possible to purify it in this manner. Consistent curves of absorption against wave-length were taken as an indication of purity ; but in order to test the method, the pigment purified in this way was taken and adsorbed on to a cation exchange resin ('Zeo-karb 225') and eluted at controlled *p*H's. A well-defined band was obtained giving identical curves with those obtained previously.

A comparison of the absorption curves as shown in Fig. 1 indicates a certain similarity between the curves of the two pigments. The points of difference are the reversal of the heights of the peaks at 228 mμ and 280 mμ and the appearance of an additional upward trend at 200 mμ in the case of the pale yellow pigment. Besides the peaks shown, there is an additional peak at 410 mμ in both pigments, but this is slight compared with the absorption at the shorter wave-lengths.

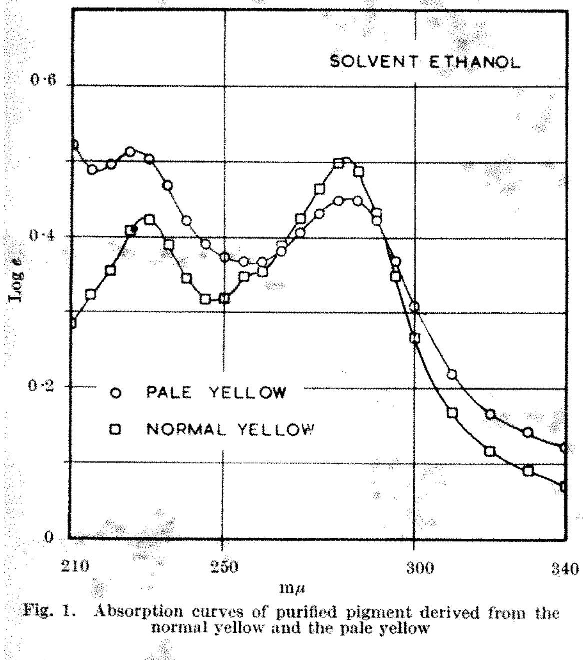

Fig. 1. Absorption curves of purified pigment derived from the normal yellow and the pale yellow

The difference promoted by the *sa* mutation is therefore one of quality rather than of quantity, and it seems reasonable to suppose that a chemical change has occurred in the structure of the pigment. The nature and biosynthetic significance of the change is not yet clear.

My thanks are due to Prof. D. Lewis and Dr. D. Wilkie for their help and criticisms. This work has been carried out with the help of a grant from the Medical Research Council.

Inheritance of β-Globulins in Serum and Milk from Cattle

Using starch-gel electrophoresis Smithies and Hickman[1] recognized five cattle β-globulin phenotypes. In a preliminary communication Ashton[2] also described five phenotypes, but after critical examination of some matings he detected a sixth phenotype[3]. The results indicated that the β-globulin types were determined by three alleles named β^A, β^D and β^E, with no dominance[1,3]. However, usually it seems to be difficult to distinguish the two phenotypes *D*/*E* and *E*/*E*.

In order to improve the separation of the β-globulins some modifications of the technique of Smithies[4] with horizontal gel were applied in the present work. A *tris*-buffer *p*H 8·9 (*tris*hydroxymethylaminomethane, sigma 7–9, 20·2 gm./l., ethylenediamine tetraacetic acid, 2·0 gm./l., and boric acid, 1·5 gm./l.) was used as electrolyte. A similar, but more concentrated, buffer has been described by Aronsson and Grönvall[5]. In the present work starch gels were prepared from 36·6 gm. acid-hydrolysed potato starch in a dilution of 90 ml. electrolyte and 210 ml. distilled water. A voltage gradient of 7 V./cm. was applied for 6 hr. with gels having a dimension of 220 × 130 × 6 mm. This system has the advantage that the separation of the β-globulins is improved, the procedure is of shorter duration, and only one kind of buffer is needed. Eight samples inserted with the starch grain method can be analysed every time. A slice, 2 mm. thick, in the middle of the gel is stained in a solution of amido-black 10 *B*. For routine work, it is possible with the present method to insert 2 × 8 serum samples on pieces of Whatman *E*17 filter paper (8 samples 3 cm. and 8 samples 12 cm. from the cathodic side) and to reduce the time for the experiment from 6 to 4 hr.

The six β-globulin types are shown in Fig. 1. There is a close agreement between these types and those shown diagrammatically by Ashton[3]. However, the phenotype *E*/*E* often has a faint fourth band but it is always possible to distinguish it from the *D*/*E*-type. The type *A*/*E* has five bands only, but the middle band is sometimes a little broader than the others. Ashton[3] recognized six bands in this phenotype.

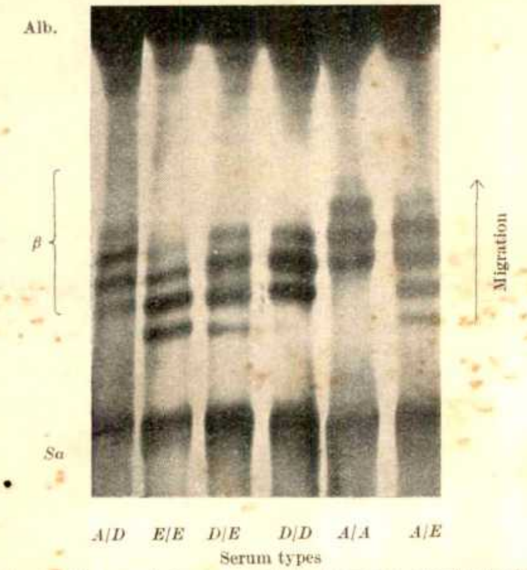

Fig. 1. Photograph from an analysis of cow sera, showing typical examples of the six β-globulin serum phenotypes. Alb., albumin; β, β-globulin; Sa, slow α-globulin

Serum samples from 707 animals of the Swedish Red and White Cattle breed (*SRB*) belonging to four different herds have been analysed. The estimated gene frequencies, $\beta^A = 0{\cdot}4682$, $\beta^D = 0{\cdot}2263$, and $\beta^E = 0{\cdot}3055$, are quite different from those found by Ashton[3] and Højgaard[6]. The results in Table 1 indicate a close agreement between the observed distribution of serum types and that expected under genetic equilibrium. It is, however, noteworthy that there is a deficiency of individuals in all three homozygous classes, and a corresponding excess of the three heterozygous types.

Table 1. OBSERVED AND EXPECTED DISTRIBUTIONS OF SERUM TYPES IN CATTLE FROM FOUR DIFFERENT HERDS OF SWEDISH RED AND WHITE BREED

	Serum types						Total
	A/A	*A/D*	*D/E*	*D/D*	*E/E*	*A/E*	
Observed Expected	147 154·97	151 149·82	103 97·76	33 36·21	56 65·99	217 202·25	707
DF = 3	$\chi^2 = 3{\cdot}57$			$0{\cdot}50 > P > 0{\cdot}30$			

Serum samples from 25 pairs of like-sexed cattle twins classified as possibly monozygous because of morphological similarity were analysed. In 6 twin pairs the two members showed different serum types. They were also shown to be dizygous in red cell antigen tests. The twins in one of these 6 pairs had distinctly different erythrocyte types while the remaining 5 sets showed erythrocyte mosaicism (an admixture of two different red cell types). Therefore, it is evident that the β-globulin types are not influenced by the fœtal vascular anastomosis occurring in most twin pairs. The red cell antigen test for dizygosity is relatively laborious and sometimes also difficult to interpret in dizygous twins having erythrocyte mosaicism[7]. Thus, the β-globulin test provides a short method with which at least a part of the dizygous pairs will be detected.

Some samples of cow milk (colostral as well as normal) treated as described by Aschaffenburg and Drewry[8] in their investigation on β-lactoglobulins were also subjected to starch gel electrophoresis. In addition to the rapidly moving β-lactoglobulin and α-lactalbumin the colostrum samples showed some components with a pattern and a migration-rate corresponding to the serum β-globulins of the same cows (Fig. 2); also a protein band in the post albumin zone could be seen. With normal milk taken 2 months after parturition the globulin-like pattern was very faint. A component with a migration-rate comparable to fast α_2-globulin appeared clearly.

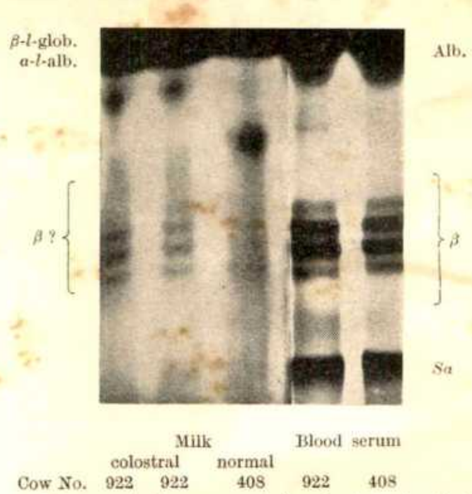

Fig. 2. Photograph from an analysis of colostral milk from cow No. 922 (3 days after parturition), normal milk from cow No. 408 (2 months after parturition), and blood serum from the same cows, classified as *D/E*. β-l-glob., β-lactoglobulin; α-l-alb., α-lactalbumin

VIROLOGY

Crystallization of Purified Mouse Encephalomyocarditis Virus Particles

MOUSE encephalomyocarditis virus is one of a group of viruses known to be pathogenic to a variety of animals[1]. Partial purification of the virus has been reported using protamine precipitation of extracts of infected mouse brain and the virus particle was found to be 27 mμ in diameter[2]. Recently, it was shown that the virus could be adsorbed on and eluted from columns of calcium phosphate without destroying infectivity[3]. In order to obtain analytical data on the composition of the virus and to perform biochemical studies on the effect of virus multiplication on the metabolism of Krebs ascites cells, we have developed a method for the purification and crystallization of encephalomyocarditis virus.

The strain of encephalomyocarditis virus used was obtained through the courtesy of Dr. Kingsley Sanders, and its origin has been described[4].

Complete details of the method of growing this virus on a large scale will be published shortly. An outline of the method is given here. Krebs II mouse ascites cells were suspended in Earle's medium to a final concentration of 2×10^7 cells/ml. and were inoculated with an unpurified virus suspension containing about three infective particles per ascites cell. The suspension of infected cells (in 100-ml. lots) was incubated at 37° for 18 hr. After this time the cells were spun down at 2,000*g* for 10 min. at 4° C. The supernatant was then centrifuged at 11,000*g* for 10 min. at 4° C. and the supernatant centrifuged for 60 min. at 105,000*g* in a 'Spinco' preparative ultracentrifuge. The 'Spinco' pellets from three such cultures were combined and suspended in 0·02 *M* sodium phosphate buffer, *p*H 7·0. Purified trypsin was added to a final concentration 0·01 per cent and the suspension incubated 60 min. at 37° C. The brownish-coloured solution was diluted threefold (usually to 30 ml.), and applied to a column (25 mm. diameter, 8 cm. long) previously packed with calcium phosphate in 0·02 *M* phosphate buffer, *p*H 7. Calcium phosphate used for chromatography was prepared as described by Taverne, Marshall and Fulton[3]. A phosphate gradient was then applied to the column by allowing 125 ml. 0·5 *M* sodium phosphate (*p*H 7·0) to siphon from a 175-ml. conical flask into a cylindrical mixing chamber (4·5 cm. diameter) which initially contained about 90 ml. 0·02 *M* phosphate (*p*H 7·0). The virus was eluted when the inorganic phosphate concentration of the eluate was between 0·2 and 0·3 *M*. Virus concentration in the fractions was measured by hæmagglutination.

Concentrated virus was usually contained in about 15 ml. of column effluent. This was dialysed for 3 hr. at 4° C. against 0·02 *M* phosphate buffer. After dialysis the material was applied to a second calcium phosphate column (9·5 mm. diameter, 10 cm. length) and eluted as described for the first column. Fractions rich in virus were again pooled and centrifuged for 60 min. at 105,000*g* in the ultracentrifuge. The white pellet which formed was drained free of the supernatant and dispersed in 0·1 ml. sterile saline (0·9 per cent w/v sodium chloride). The tube containing the virus suspension in saline was stoppered and left at 4°, and within 48 hr. crystals had deposited.

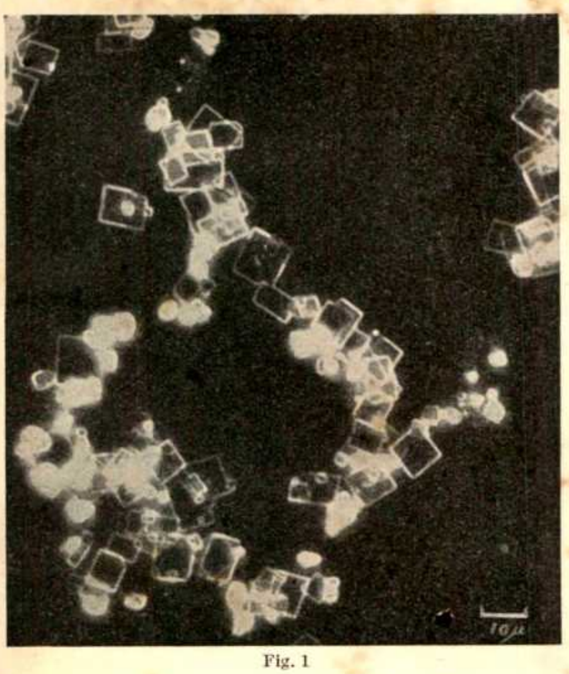

Fig. 1

A photograph of the crystals obtained by dark-field microscopy is given in Fig. 1 (× 600). The crystals have the form of rectangular wafers. When mounted in saline they exhibit Brownian movement and are quite thin, their thickness being about 10 per cent of their length. An X-ray scatter diagram of a suspension of the crystals was obtained by Mrs. Kennard of this Institute. The photograph showed a repeating pattern characteristic of macromolecular organization.

The crystals dissolved in phosphate-buffered saline at *p*H 7·3 show an absorption maximum in the ultra-violet at 258 mμ and a minimum at 240 mμ. Analysis of the crystals showed that the ratio ribonucleic acid/total nitrogen was 2·12. This result indicates that the virus contains about 30 per cent ribonucleic acid.

Dispersion of the crystals in phosphate-buffered saline gave a suspension containing infective virus particles with the following biological activities:

Hæmagglutination units/mgm. ribonucleic acid = $2 \cdot 32 \times 10^6$

Plaque-forming units/mgm. ribonucleic acid = 5×10^{12}

Although encephalomyocarditis virus particles have approximately the same shape and ribonucleic acid composition as those from *MEF*-1 poliomyelitis[5], the crystal form of the two viruses is quite distinct. Poliovirus crystals are tetragonal prisms with pyramids at each end, whereas the encephalomyocarditis virus forms rectangular wafers.

Influence of Route of Inoculation and Strain of Mouse on Infectivity Titrations of the Virus of Foot-and-Mouth Disease

In the original experiments in which fatal infection of unweaned white mice with strains of the virus of foot-and-mouth disease was first demonstrated[1], the mice appeared to be equally sensitive to inoculations by the intracerebral and intraperitoneal routes. Because of its greater convenience, the intraperitoneal route has been adopted as a standard method of infecting mice four–eight days old. We have now found that mice of this age are more susceptible to infection with most strains of the virus if the inoculation is made at other sites, namely, the muscles of the hind limbs and the pectoral region, or subcutaneously beneath the raised dorsal skin.

Virus strains of widely different history were titrated simultaneously using the intraperitoneal route, and one or more of these other routes in mice four–eight days old. The volume of inoculum was constant in any one experiment, but in different experiments volumes varied between 0·02 and 0·05 ml. Using a five-fold series of virus dilutions, at least six mice were inoculated at each dilution by each route.

To reduce the variation between litters and to obtain an error estimate (H. S. S., in preparation) the unweaned mice were randomized among the mothers —eight–ten mice per mother—and all the dilutions distributed within every litter. Two mice per dilution per litter and separate litters for each route were usually used. 50 per cent end-point dilutions were estimated by the Spearmann–Kärber method[2]. Under these conditions, a measure of the precision of the 50 per cent end-point estimates is given by the average variance of individual litter end-points ($\overline{V}x$). Our $\overline{V}x$ estimates, in $\log_{10}$ units, for randomized five–seven day old mice of the Pirbright *P* strain with the number of degrees of freedom on which these estimates are based (in brackets) are: Intraperitoneal, 0·1119 (158); intramuscular pect., 0·1258 (41); subcutaneous, 0·1307 (20); intramuscular, one limb 0·1701 (12); intramuscular, two limbs, 0·1137 (71).

In a few experiments the unweaned mice were not randomized, but different routes of inoculation at the same dilution were randomly distributed within every litter.

Our results with the Pirbright *P* strain of mouse are shown in Fig. 1. The following are our general conclusions. (1) *P* strain mice are almost invariably more sensitive to these virus strains when inoculated by the intramuscular limb, intramuscular pect. or subcutaneous routes. The difference is significant at the 5 per cent level in about 60 per cent of the comparisons. (2) There is good agreement between the 'route difference' results obtained with any one virus strain in repeated experiments. These were often done after an interval of many weeks and different virus suspensions were generally used. The estimated 95 per cent fiducial limit of the difference between two such 'route difference' results is 0·62 $\log_{10}$ units. (3) The magnitude of the difference between any two routes depends on, and is a characteristic of, the strain of virus used. We could not establish a correlation with any viral property such as myotropicity, dermotropicity, immunological type or passage history. (4) Tests using the two intramuscular routes are of about equal sensitivity within the limits of our experimental error, and appear to be more sensitive than tests using the subcutaneous route. In some of the experiments simultaneous comparisons were made also in older mice. Susceptibility to infection diminished with increase in age less rapidly in intramuscularly than in intraperitoneally inoculated mice.

The effect of the volume of inoculum on the 50 per cent end-point dilution was investigated in mice a week old in several experiments with the 119 mouse-passaged strain. Volumes of 0·01 ml. and less were inoculated with a microsyringe. The efficacy of the various volume-levels was compared by calculating the *ID*50/ml. of the initial virus suspension. The intraperitoneal and subcutaneous routes were tested by inoculating volumes ranging from 0·001 to 0·27 ml., and no significant or consistent variation in the *ID*50/ml. was detected. The intramuscular limb route (inoculating only one limb) also showed no such variation over the volume range 0·0001–0·01 ml.; but when increased to 0·03 and 0·05 ml. (two experiments) the *ID*50/ml. was less than that expected by $\log_{10}$ 0·46, 0·53 and 0·71 respectively. For maximum efficiency of this route, the volume inoculated per limb should not therefore exceed 0·01 ml.

Only *P* strain mice were used in the experiments so far discussed. Using this strain as a control, the relative susceptibilities to infection by the intraperitoneal and intramuscular (two limbs) routes of inoculation have been investigated in mice of the same age from six of the other strains of mice maintained at this Institute. Experiments were so designed that any change in the infectivity of virus

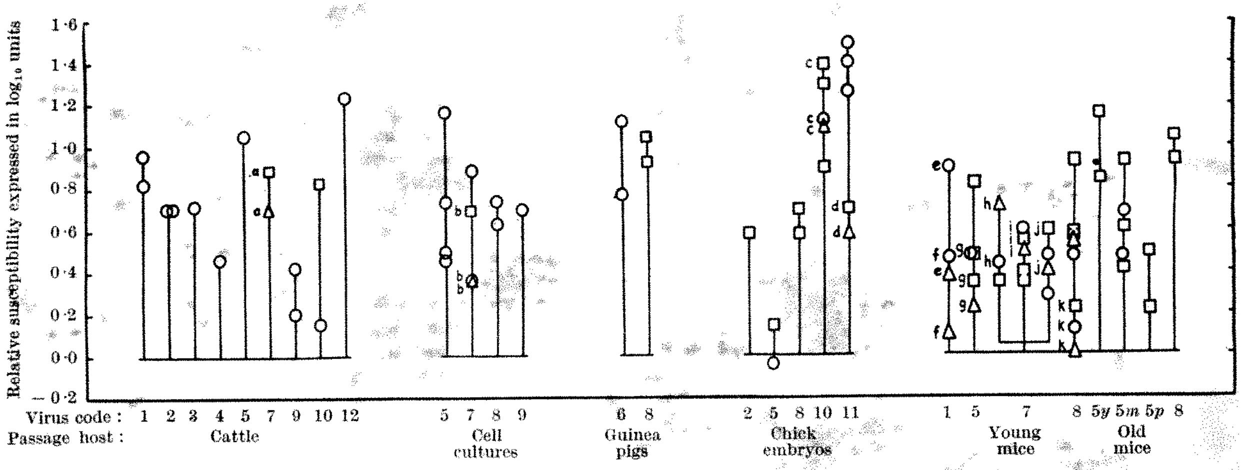

Fig. 1. Relative susceptibility of *P* strain mice to infection with strains of the virus of foot-and-mouth disease inoculated by different routes using the intraperitoneal route end-point as a base-line (0·0). Simultaneous comparisons are indicated by the same letter. ○, Intramuscular, limb; □, intramuscular, pect.; △, subcutaneous.

Virus code: 1–6. Strains 39, Ven. 1, A.S.J., Dutch 0, M.11, and 1, respectively, all type Vallée 0. 7–12. Strains 119, 997, R.V.11, Rho.1, R.V.7, and Pak. 1, types Vallée A, Waldmann C, S.A.T.1,2,3, and Asia 1 respectively dilutions during the period of the inoculations could not enhance or minimize any differences attributable to the mouse strain or route of inoculation. Usually, four or five randomized litters of ten mice were used per mouse strain per route. The results will be published in detail elsewhere (H. S. S., in preparation).

The following general points have emerged:

(1) Some of these mouse strains differ by as much as 1·3 $\log_{10}$ units in their susceptibility to infection by the intraperitoneal route used.

(2) Irrespective of the susceptibility to infection of a mouse strain, the intramuscular limb 50 per cent end-point is with almost all virus strains higher than the intraperitoneal 50 per cent end-point. Actually, 19 out of 22 experiments with 14 different virus strains showed a difference from 0·1 to 1·5 $\log_{10}$ units in favour of the intramuscular route (43 separate comparisons). In the remaining 3 experiments the difference varies from 0·0 to 0·5 in favour of the intraperitoneal route (6 separate comparisons).

(3) Two mouse strains (Pirbright *B* and *G*) are less susceptible to infection than the *P* strain. They consistently gave lower 50 per cent infective end-point dilutions when the intraperitoneal route and the intramuscular (two limbs) route were compared. In addition they appear to be more variable, as the $\overline{V}x$ estimates for these strains are considerably higher than the corresponding *P* strain estimates.

(4) Three mouse strains (Pirbright *A*, *C* and *C*57) are more susceptible to infection than the *P* strain. With one exception, the only mouse-passaged strain tested (see 6, below), they consistently gave higher end-points when the intraperitoneal route was compared and also in 16 out of 21 comparisons of the intramuscular route. The $\overline{V}x$ estimates of these strains are very similar to those of the *P* strain.

(5) The magnitude of the difference between the intramuscular and intraperitoneal routes with any given virus strain depends also on the mouse strain in which the comparison is made. Thus in two experiments with virus strain *RV* 7, differences found in *P* strain mice were 1·4 and 1·5, while in *A* strain mice they were respectively 0·4 and 0·7 $\log_{10}$ units.

(6) Experiments with virus strain 119 at its 292nd intraperitoneal passage in unweaned *P* strain mice suggest specific adaptation of the virus to the unweaned *P* strain mice, when the accustomed route of inoculation is used. We have found the intraperitoneal end-point consistently higher in *P* strain than in *A* strain, but the reverse is true for the intramuscular end-point.

As the $\overline{V}x$ estimate for tests made by the intraperitoneal route is as low as that of more sensitive tests made by the intramuscular or subcutaneous routes, the intraperitoneal route of inoculation remains a suitable one for titrations of infectivity when relative concentrations of virus are being estimated. However, when materials suspected of containing only traces of virus are tested, the more sensitive test routes should be used. These routes should also be of value when particle counts are being correlated with infectivity. Additional improvement of sensitivity may be achieved by choosing a more sensitive mouse strain than the one which is in use. Our results indicate that different laboratories may at present be using mouse strains differing in their susceptibility to infection by at least a factor of ten.

When an attempt is made to compare the susceptibility of different mouse strains, virus pre-adapted to one of the strains should not be used.

Simultaneous titrations of most cattle strains of virus intraperitoneally in unweaned mice (0·03 ml.) and intradermally on the tongues of two steers at multiple sites (0·1 ml. per site)[3] have been shown to result in similar 50 per cent end-point dilutions in both species[4], although there is a threefold difference in the volume inoculated. Our colleagues, Martin, Mowat and Pay, have since made the same observation on several occasions (personal communications). Using three cattle strains of virus, we have, in collaboration with our colleagues Davie, Davies and O'Reilly, made simultaneous titrations as above in cattle and intramuscularly (0·02 ml.) in *P* strain mice. The 50 per cent end-point dilutions in mice exceeded those in cattle by $\log_{10}$ 0·4, 0·5 and $\geqslant$ 1·7. Allowing for the difference in volume inoculated, our results indicate that the mice in these tests were $\log_{10}$ 1·1, 1·2 and $\geqslant$ 2·4 times more susceptible to infection than the cattle tongue epithelium. Alternatively, assuming that the mice and epithelium were of equal susceptibility, then, in the latter, only a fraction of the virus dose succeeds in initiating a lesion at the site of inoculation.

PSYCHOLOGY

"Self-Regulation for Children"

IN the review of our book "The Free Family", in *Nature* of April 2, p. 38, Prof. Vernon says that "it is clear that the children experienced considerable difficulty in adapting themselves to the society of children very differently brought up", and he asks for independent evidence for their "spontaneity, poise and stability".

Allow me to say that Prof. Vernon could only have gained the first false impression because we describe in detail the kind of conflicts one of our children had in a specific instance. This certainly does not imply that our children had more difficulties in 'socialization' than other children. This is particularly true for the second, third, fourth and fifth child. All their school reports have tended to stress their ability to co-operate.

The independent evidence Prof. Vernon asks for can also be supplied in part: the oldest child is one of 19 children in Nottingham to have received a free place at the Nottingham Girls' High School; further, two 'television teams' spent a whole day with the family shortly after the book came out, and although adverse points were of course made, none doubted "spontaneity, poise and stability".

We started self-regulating children when I was a student on a very meagre grant and I have always had little inclination for leisure. Flexibility we have had, more so than the normal parents, and it is useful; but money and leisure are not important criteria. We agree with Prof. Vernon that self-regulation will be practised only by a fortunate few, but the criteria of selection is likely to be vitality and capacity to love, both symptoms of psycho-somatic health.

PAUL RITTER

7 Magdala Road,
Nottingham.

IT may well be that enthusiasm on the part of the parents is a more essential condition than are any material circumstances for carrying out 'self-regulation' in the family successfully. Nevertheless, the success of this procedure can be adequately assessed only from studies made by independent psychological observers of a fair sample of such families and of the personal and social adjustment of the children.

MISCELLANY

The Problem of Language in Publications of Works in Scientific and Other Fields of Learning

THE predominance of the English language in modern scientific and technical literature, of which the research workers and writers of reviews are well aware, was clearly demonstrated in an important report published by Unesco[1] on different aspects of the language problem in science and technology. It would indeed be interesting to obtain similar information on published works in other fields of knowledge.

The problem of language is not a new one and has been discussed by men of learning at different times. Significant and prophetic in this respect was the letter[2] by David Hume to Gibbon dated October 24, 1767. It concerns one of the early attempts by Gibbon to write a historical essay which he devoted to the history of the Swiss Republic. In the selection of this subject he was influenced by his Swiss friend Deyverdun and the feeling he had for Switzerland as his country by adoption. He began to work on this essay in 1764 when, as he wrote: "The *Decline and Fall of Rome* I still contemplated at an awful distance. . . ".

"It is but a few days ago," wrote Hume, "since Deyverdun put your manuscript into my hands, and I have perused it with great pleasure and satisfaction. I have only one objection derived from the language in which it is written. Why do you compose in French, and carry faggots into the woods, as Horace says with regard to Romans who wrote in Greek? I grant that you have a like motive to those Romans, and adopt a language much more generally diffused than your native tongue: but have you not remarked the fate of those two ancient languages in following ages? The Latin, though then less celebrated, and confined to more narrow limits, has in some measure outlived the Greek, and is now more generally understood by men of letters. Let the French, therefore, triumph in the present diffusion of their tongue. Our solid and increasing establishments in America, where we need less dread the inundation of Barbarians, promise a superior stability and duration to the English language.

"Your use of the French tongue has also led you into a style more poetical and figurative, and more highly coloured, than our language seems to admit of in historical production. . . ."

Reflecting on some defects of his essay, Gibbon wrote[2]:

"My ancient habits, and the presence of Deyverdun, encouraged me to write in French for the continent of Europe; but I was conscious myself that my style, above prose and below poetry, degenerated into a verbose and turgid declamation. Perhaps I may impute the failure to the injudicious choice of a foreign language. Perhaps I may suspect that the language itself is ill adapted to sustain the vigour and dignity of an important narrative. . . ."

One may ask to what extent Hume's letter and these reflexions influenced Gibbon, when he was ready for his work on the "Decline and Fall of the Roman Empire", in adopting for it a language more suitable "to sustain the vigour and dignity of an important narrative"[2]. Hume's letter reflected no prejudice on his part against France, where he lived for several years, enjoying the friendship of many distinguished persons, and where he found more admirers than in his own country[3]. On the contrary, this letter illustrates the generally accepted unrivalled position then occupied by the French language among men of learning, a position which had already been recognized before Hume's time and which was held for almost a century following his letter to Gibbon. Educated people and scholars of different countries read in French the works of the great French philosophers, writers and scientists, and many of them could write and speak in French as well as in their mother tongues. It is therefore not surprising that many of the universally admired works of learning both in science and letters, published in France from the beginning of the eighteenth until the middle of the nineteenth century, were not translated into other languages, including English.

The fact that the English language is on the way to occupying, at least in some respects, the position previously held by the French language, fulfils Hume's prophecy beyond anything he could have contemplated, especially if we consider the rapidly growing activity in different fields of learning and the production of works of marked scholarship in the country which he referred to as our "solid and increasing establishments in America".

Although there is no sign yet that the prevalent use of the English language is abating, or has even reached its peak, one must not forget Hume's remark as to the fate of other, once dominant, languages. Moreover, the prevalence of one language does not necessarily imply a loss of interest in the others. On the contrary, this interest, being freed from more practical purposes, will not cease to be stimulated by the desire to appreciate and enjoy more fully the cultural life of the corresponding country, which can scarcely be satisfied without the knowledge of its language.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, June 13

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8 p.m.—Annual General Meeting.

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. S. Sambursky: "Conceptual Developments in Greek Science".

Tuesday, June 14

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.45 p.m.—Mrs. S. J. Hallam: "Some Aspects of Romano-British Settlements Round the Wash".* (Last of nine lectures on "Recent Archæological Discovery in Britain").

Wednesday, June 15

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 10 a.m. and 2.15 p.m.—Meeting on "Oxidation of Mild Steel".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. B. J. Mason and Mr. J. Maybank: "The Fragmentation and Electrification of Freezing Water Drops"; Mr. R. J. Murgatroyd and Mr. M. P. Garrod: "Observations of Precipitation Elements in Cumulus Clouds"; Mr. F. Singleton: "Aircraft Observations of Rain and Drizzle from Layer Clouds".

University College, Department of Pharmacology (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. H. Wirz (Basle, Switzerland): "The Mechanism of Urinary Concentration and Dilution"* (The Renal Association—Tenth Anniversary Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. A. H. Cottrell, F.R.S.: "The Strength of Solids".

Thursday, June 16

British Institute of Radiology (in the Library, 32 Welbeck Street, London, W.1), at 4 p.m.—First Meeting of the Discussion Group.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. Sir John Eccles, F.R.S.: "The Nature of Central Inhibitory Action" (The Ferrier Lecture).

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. R. V. Kadison: "Some Aspects of Spectral Theory".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Annual General Meeting, followed by Sir Philip Manson-Bahr: "Around the World in 35 Days", illustrated by lantern slides.

Friday, June 17

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 2 p.m.—Radiobiology Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist (non-medical), for research on problems connected with tropical diseases—The Secretary, Hospital for Tropical Diseases, 4 St. Pancras Way, London, N.W.1 (June 17).

Research Fellows (2) in the Department of Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (June 17).

Assistant, Grade "B", in Physics—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4 (June 18).

Assistant in the Department of Moral Philosophy—The Secretary, The University, Edinburgh (June 18).

Lecturer (graduate in engineering or physics, and preferably experience of experimental reactor physics or heat transfer) in Nuclear Engineering—The Registrar, The University, Manchester 13 (June 18).

Lecturer to take charge of Metallurgical Teaching and Research in the Department of Mechanical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (June 18).

Chair of Biochemistry—The Secretary of the University Council, Trinity College, Dublin (June 20).

Lecturer (preferably with experience with high vacuum and plasma devices, and a serious interest in research) to teach the theory and practice of electronics as applied to vacuum and gas discharge devices—Prof. A. Tustin, Department of Electrical Engineering, Imperial College of Science and Technology, London, S.W.7 (June 20).

Research Student (with a good honours degree, preferably in organic chemistry or in biochemistry) in Pharmacology—The Registrar, Trinity College, Dublin (June 20).

Scientific Officer or Senior Scientific Officer (honours graduate in chemistry, preferably Ph.D. with experience in research in radiation chemistry or microbiology, and familiar with the use of radiation sources, dosimetry and protection of personnel) at the Low Temperature Research Station, Cambridge, to work in a group studying the preservation of foods with ionizing radiations—The Secretary, Low Temperature Research Station, Downing Street, Cambridge (June 21).

Assistant Lecturer in Applied Mathematics (Digital Computing)—The Secretary, The Queen's University, Belfast (June 22).

Lecturers (with a good honours degree, and preferably with teaching experience) in (*a*) Physics and (*b*) Chemistry at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (June 24).

Mycologist (preferably with some postgraduate experience) in the Soil Bureau, Department of Scientific and Industrial Research, Wellington, New Zealand, to join a team doing research in soil processes—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. B.11/21/28 (June 24).

Assistant in Applied Mathematics—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (June 25)

Assistant Lecturer in Geology—The Secretary, The University, Exeter (June 25).

Sub-Librarian (Science Library) (graduate preferably in science, or with good experience in scientific librarianship)—The Registrar, The University, Nottingham (June 25).

Lecturer (with good academic qualifications and industrial or other experience in electric power engineering, electrical machines, electrical measurements, or control engineering) in the Department of Electrical Engineering—The Registrar, The University, Leeds 2 (June 27).

Temporary Lecturer or Assistant Lecturer in Zoology—The Secretary, The University, Exeter (June 27).

Curator (with a good general knowledge of botany and wide experience of all branches of horticulture, ability to control a large staff and a knowledge of all aspects of running a large scientific horticultural establishment, and preferably a degree in an appropriate subject or with the National Diploma of Horticulture) of the Royal Botanic Gardens, Kew, Surrey—The Civil Service Commission, Burlington Gardens, London, W.1, quoting 5148/60 (June 28).

Assistant Keeper (with a university degree, and preferably with the Museums Association Diploma or museums' experience) of Archæology—The Curator, Castle Museum, Norwich (NOR 65b), Norfolk (June 30).

Assistant Lecturer (with a degree in botany with some zoology) in Biology—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Chair of Electrical Engineering—The Secretary, The University, Old College, South Bridge, Edinburgh (June 30).

Demonstrator in the Department of Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Lecturer in Statistics—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Lecturer (with a registrable veterinary qualification and postgraduate experience in bacteriology) in Bacteriology in the School of Veterinary Medicine—The Registrar, Trinity College, Dublin (June 30).

Lecturers (2) in Civil Engineering—The Registrar, The University, Nottingham (June 30).

Research Fellows or Associates in the Department of Chemistry, for work on either biochemical or chemical aspects of bacterial cell walls and related subjects—The Registrar, King's College (University of Durham), Newcastle upon Tyne (June 30).

Leverhulme Research Fellow (with previous experience of homografting or related fields) in the McIndoe Memorial Research Unit, to investigate the problem of homografting—The Secretary, East Grinstead Research Trust, Queen Victoria Hospital, East Grinstead, Sussex (July 1).

University Assistant Lecturer (preferably with a knowledge of either East or Central Africa, or the Pacific area) in Social Anthropology—The Secretary of the Appointments Committee, Faculty of Archæology and Anthropology, The University, Downing Street, Cambridge (July 2).

Research Assistant (with a university degree in physics or chemistry, and preferably experience in the investigation of dusts) in Industrial Hygiene in the Department of Social and Preventive Medicine—Prof. John Pemberton, The Queen's University, Belfast (July 6).

Lecturer in the Department of Physics—Prof. P. M. S. Blackett, F.R.S., Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7 (July 7).

Reader in Physiology at the Royal Free Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 8).

Research Assistant (with a good honours degree in botany or agricultural botany and an interest in experimental ecology and/or genetics) in Agricultural Botany, for investigations on the mineral nutrition of natural populations of agriculturally important grass species—The Registrar, University College of North Wales, Bangor, North Wales (July 15).

Senior Assistant (with a degree or substantially equivalent qualifications in physics or electrical engineering or other approved subject, and experience in previous employment) in Research in the Cavendish Laboratory—Dr. F. B. Kipping, Chemical Laboratory, The University, Lensfield Road, Cambridge (July 15).

Second Chair in Agriculture at King's College, Newcastle upon Tyne—The Registrar, University Office, 46 North Bailey, Durham (July 30).

Assistant Lecturer or Lecturer in Veterinary Parasitology—The Registrar, The University, Liverpool, quoting Ref. CV/T (July 31).

Senior Lecturer in Chemistry at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 31).

Laboratory Technician (with experience in laboratory procedures in hæmatology) in the Department of Physiology in the University of New England, Armidale, N.S.W., Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, August 15).

BIOCHEMIST (Basic grade) IN THE LABORATORY, Ayrshire Central Hospital, Irvine—Area Medical Superintendent, Ayrshire Hospitals, 1 Hill Street, Kilmarnock, Ayrshire.

CATALOGUER/ABSTRACTOR (competent cataloguer with scientific or technical library experience) in the Headquarters of the Technical Information Service at Hatfield Technical College—The Registrar, Hatfield Technical College, Roe Green, Hatfield, Herts.

LECTURER (preferably with experience in high polymer chemistry, together with teaching and/or industrial experience) IN THE DEPARTMENT OF CHEMISTRY, COLOUR CHEMISTRY AND DYEING, to teach physical chemistry to the Dip.Tech. and G.R.I.C. standard—The Principal, Huddersfield College of Technology, Huddersfield.

MEDICAL LABORATORY TECHNICIAN (qualified A.I.M.L.T., or with a science degree or equivalent)—The Administrative Officer, North London Blood Transfusion Centre, Deansbrook Road, Edgware, Mddx.

RESEARCH ASSISTANT, and EXPERIMENTAL OFFICERS (2) (PHYSICISTS or ENGINEERS interested in working on high temperature hypersonic flow research)—Head of the Aeronautics Department, Imperial College of Science and Technology, London, S.W.7.

RESEARCH ASSISTANT (with a Ph.D. degree in physical chemistry or physics) IN CHEMISTRY, to work on the reaction of metals with gases at elevated temperatures—The Secretary, The University, Exeter.

RESEARCH STUDENTS (with a good honours degree or equivalent qualification, undergraduates in their final year will also be considered, IN CHEMISTRY, CIVIL ENGINEERING, ELECTRONICS, METALLURGY) PHARMACY AND PHYSICS—The Registrar, Technical College, Sunderland, Co. Durham.

SENIOR EXPERIMENTALIST (with G.C.E. at "A" level, H.N.C. or their equivalent, and (*a*) considerable experience in the design and manufacture of special electronic devices, and (*b*) a knowledge of the latest advances in pulse counting and timing techniques), to be responsible for the operation, maintenance and improvement of a complex electronic counting installation associated with a linear accelerator—The Personnel Manager (1695/34), U.K.A.E.A., A.E.R.E., Harwell, Didcot, Berks.

SENIOR TECHNICIAN (fully conversant with general workshop practice, and with practical electrical experience) IN THE DEPARTMENT OF X-RAY TECHNOLOGY of the Churchill Hospital, Oxford—The Assistant Administrator, Radcliffe Infirmary, Oxford.

TECHNICAL OFFICER (with a degree or diploma in agriculture or agricultural botany) IN THE CEREALS SECTION OF THE SEED PRODUCTION BRANCH—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

THE TRAINING OF POSTGRADUATE STUDENTS

A JOINT committee appointed by the Institute of Physics and the Physical Society has prepared an admirable report on the postgraduate training of physicists in British universities. Besides university professors of physics its members included industrialists of the standing of Dr. R. Beeching, who is a director of Imperial Chemical Industries, Ltd., and some twenty other physicists attended one or more of its meetings to give their views. The report[*] does not claim to be more than a first step in investigating a very big problem, and is, in fact, concerned mainly with problems arising in training those who are working for the Ph.D. degree, including the suitability of that degree as a preparation for fundamental and applied research. It is packed with common sense and, taken with the lecture on "The Education of Chemists" which Prof. T. L. Cottrell delivered at Edinburgh last November, with which the report may appropriately be read, it affords clear evidence of fresh thought about the nature and content of university courses, and indeed of professional courses both inside and outside the universities. In fact, issues are raised if not fully discussed which should certainly be considered by the Royal Institute of Chemistry in determining points of policy arising out of the tentative proposals for a new grade of membership and category of affiliation.

In British universities postgraduate training in science has been essentially preparation for the Ph.D. degree: the bachelor's degree with honours has been, and is still, the qualification which often represents the completion of a future scientist's formal university education, and at this stage many graduates, including some of the ablest, enter government and industrial laboratories for careers which may include original and fundamental research. The view was put to the Committee that in any foreseeable circumstances the recruitment of adequate numbers of Ph.D. students is essential for the vitality of university departments which are actively concerned with the advancement of knowledge. Without questioning the view that the prosecution of original research is a major university responsibility, and recognizing the existence since the Second World War of a large and only partly satisfied demand from industry and from government departments for graduates in physics for research and development, the Committee sees postgraduate training as an aspect of the wider issue of the most effective use of scientific ability of a high level. Its scrutiny is penetrating and some of its comments are strikingly similar to those of Prof. Cottrell on the training of chemists.

The report points out that the training of the research worker in British universities rests upon four assumptions. First, it presupposes enlightened supervision in an atmosphere of maturity. Secondly, it assumes that all the research students have the innate qualities that will allow them to profit by this form of training. Implied in this assumption is successful selection, and that those who gain a research degree will be characterized by manifest research ability and maturity. Thirdly, it assumes that physicists of the highest potential ability will benefit from a broadly similar method of research training whatever their ultimate work may be, though it is recognized that in the past theoretical physicists have tended to come from those trained as mathematicians. Fourthly is the assumption that the present level of the first degree is the appropriate stage at which the basic and common education of a scientist may cease, and that additional knowledge required to be gained beyond this stage is knowledge of a specialized nature determined by the field of research being undertaken.

It is against this background that the Committee examined criticisms made of present practice in Britain, some of which imply a complete denial of one or more of the assumptions. From within the universities the adequacy of the three-year undergraduate course has been questioned and a four-year course has been advocated purely on the ground of the growth of physics itself in recent years. While the report makes no comment on an important point made by Prof. Cottrell that scientific advances, by including more facts in the scope of a wider generalization, may reduce rather than increase the amount of information to be memorized, the Committee clearly recognized serious practical difficulties in increasing the length of undergraduate courses; and the practical suggestion made by the Committee is rather the desirability of a further one-year university course for selected students.

It is the industrial criticism that is strikingly parallel with Prof. Cottrell's comments on the training of chemists. The chief defects in the quality of Ph.D. graduates recruited are lack of scientific originality, lack of good theoretical knowledge of physics and lack of flexibility and adaptability. The first is primarily a criticism of the selection of research students, or of the unwillingness of universities to refuse to award the degree to those once accepted; but it could also be a criticism of poor supervision and of bad selection of problems tackled, which might stifle scientific originality. It is the most serious of the criticisms that can be made against the universities in this respect.

The second criticism is widespread, but is made on two different grounds. First, it is suggested that the Ph.D. graduates sometimes lack adequate theoretical knowledge of even the fields in which they have undertaken their research, though from Prof. Cottrell's criticism of the graduate in chemistry it could be due to failure to apply theory and instead to resort to the purest empiricism. With this could also go the absence of a sufficiently critical and inquiring attitude to a research problem. Secondly, some employers seem to expect the holder of a Ph.D. degree to possess a deeper theoretical knowledge of physics over quite a wide front than could be expected in a graduate with a first degree. That criticism, however, could scarcely be advanced if the graduate had, as Prof. Cottrell insists, been adequately trained and encouraged to read and think for himself and to make adequate use of the literature.

---

[*] The Postgraduate Training of Physicists in British Universities: The Report of a Joint Committee appointed by the Institute of Physics and the Physical Society. Pp. 19. (London: Institute of Physics, 1960.) 2*s*.

The third criticism is also widely held and certainly strongly held, and though it is the most surprising of the criticisms noted in this report, it finds some support in Prof. Cottrell's observations on chemists. All these criticisms, however, are essentially criticisms of detail and do not necessarily imply that university postgraduate training leading to a Ph.D. degree is not fundamentally a highly desirable method of preparation for entry to industry and government service. Much more fundamental criticism is implied in the view held by some important and distinguished industrialists that the necessary preparation for, or apprenticeship to, research is more profitably undertaken in a large industrial laboratory than in the atmosphere of a university research school. Industry has only a limited need for people who will work on difficult problems of pure physics; but it has great need for men of similar intellectual ability and basic training who can apply their abilities and knowledge to the varied problems of industry. These men need to be able to cross with ease the boundaries that conventionally delineate the various sciences taught and organized in universities, and the report notes that the view is widely held that postgraduate training of the Ph.D. pattern may make a man less able or willing to do this. The Committee states that it was put with force that only a small minority, probably fewer than 10 per cent, of those recruited into industry will be engaged on research for the whole of their careers of forty years or so. Evidence was presented that the possession of a Ph.D. degree had no significant bearing upon a future career, as measured, in any event, in financial terms.

It is at this point that the relevance of Prof. Cottrell's comments on the training of chemists becomes most apparent. The demand from industry for men who have had a Ph.D. training is real, but is smaller than the output of such graduates; at present, industry is compelled to take Ph.D.s whom it would have preferred to take at an earlier stage; and it was equally clear to the Committee that the number of Ph.D.s who would be sought by industry might be increased if the average quality, measured by originality, knowledge and flexibility, were raised.

The Committee states its reasoned conclusions in ten paragraphs. First, for its purpose, which is fundamentally the introduction of an undergraduate to the procedure of fundamental research, working for the Ph.D. is an admirable training; but if it is to retain its value as a hallmark of capacity for original research, the universities must be jealous of the high standard of those on whom it is conferred. Next, the research student plays an important part in maintaining the vitality of a university physics department: without a sufficient number of such students the Committee believes it would not be possible to maintain an appropriate output of fundamental research, or to retain or recruit academic staff of suitable character. It points out, however, that the universities must ensure—which is not always the case at present—that research students are not employed partly as high-grade technicians; but it passes off a problem which is very real in some university departments, involving questions of status and prejudice, and it may be wondered whether the implications of the proposals of the Royal Institute of Chemistry to form a Registered Chemical Assistants Group, affiliated to the Institute, have been thought out sufficiently.

It may be recalled that Prof. Cottrell roundly challenged the value of much of the manipulative work customary in the training of the chemist, and his analysis is highly suggestive in respect of the physicist as well as of the physical chemist. This is not to deny the importance of such work, or to suggest that the career of laboratory technician should not be satisfying and highly regarded in its own right: not nearly enough is, in fact, done to encourage young people with manual dexterity and skill to take up such a career. What is wrong is to suggest that the career of laboratory technician is necessarily a stepping-stone to that of scientist or technologist, or that the technician's skill is necessarily linked with high intellectual ability. There may be the odd technician with such gifts which will carry him naturally to a seat on the main board of such a company as Imperial Chemical Industries, Ltd.; but he is the exception, and the technician is best served by honouring his or her special skill in its own right, rather than by encouraging ambitions which will generally be doomed to disappointment.

The appropriate and more extensive use of technicians is a problem which deserves much more attention than it has yet received and itself bears closely alike on the most efficient use of highly trained man-power and on the research output of a university department. Further, it is possible that some way may be found here of diminishing the pressure on the academic staff and thus helping to meet other criticisms of postgraduate training. While the Committee believes that the standard of the Ph.D. degree in physics is at least as high as in most other subjects, it accepts the view that the degree is sometimes awarded to candidates of inadequate calibre and concludes that the universities should be more critical in their selection of research students, and readier to refuse the award, even after the completion of the prescribed period of study and research. There is a strongly held opinion among employers that the standard of the Ph.D. has deteriorated significantly in the past twenty years.

Fourthly, the Committee is satisfied that industry needs physics graduates of wide knowledge, adaptability and first-class intellectual capacity, but that it would prefer that only a small proportion of its recruits had had research training for a Ph.D. degree in a university. Comparatively few jobs in industry will involve research in pure physics, and graduates who contemplate staying at the university for a Ph.D. should appreciate that the degree will not usually improve their prospects of advancement in industry. Some university teachers attribute industry's lack of enthusiasm for the Ph.D. degree to the fact that, in physics, fundamental research is very largely carried out in universities, and the Committee concludes that it would help to resolve the apparently conflicting demands of industry and the universities if more members of university staffs were aware of the problems of industry and the requirements of industrial research, and more industrialists appreciated the crucial place of research and the research student in the modern university.

Next, the Committee concludes that an extension of knowledge, beyond that appropriate to the present first-degree courses, should form part of university training at postgraduate-level, not narrowly centred on an immediate field of research, but such as to strengthen substantially the graduate's background knowledge of that part of physics in which his research is to be done. It is suggested that for most research students this teaching should be concentrated in the first postgraduate year. Many graduates who enter industry without taking a Ph.D. degree would benefit greatly from similar courses, and the Committee suggests the organization of courses so that they could be available to both groups of graduates; this would meet a real industrial need, and it might ease the problem of organization within the universities, and also assist in the assessment of students capable of staying on for research.

Finally, the Committee recognizes that the development of postgraduate courses would aggravate the serious problems of staffing which already face the universities and also that, since most university students are dependent on maintenance grants, no improvement of training on the lines suggested is feasible without provision of the necessary financial support by the grant-awarding bodies, particularly the Department of Scientific and Industrial Research.

As already noted, the Committee limited itself almost exclusively to problems arising in the training of those working for the Ph.D. degree, and it frankly recognizes that there are equally important problems involved in the further training of those who take up professional work in physics immediately after taking a first degree. Investigation of those problems involves consideration of the nature and extent of industry's need of scientific man-power, and it is to be hoped that such an investigation will be undertaken by a committee at least as representative of both the academic and the industrial aspects as that which, under Prof. N. Kemmer's chairmanship, has produced the present report, and before plans for further expansion of university and of technological education are too firmly set. Meanwhile, Prof. Kemmer and his colleagues are to be congratulated on a report which should be of considerable interest not simply to physicists but also to chemists, and to other scientists and their professional organizations, as well as to the universities.

NUCLEAR THEORY AND ITS UTILIZATION

Lectures on Nuclear Theory

By L. D. Landau and Ya. Smorodinsky. Translated from the Russian. Revised edition. Pp. vii+108. (New York: Plenum Press, Inc.; London: Chapman and Hall, Ltd., 1959.) 5.25 dollars; 45*s*. net.

Introductory Nuclear Theory

By Dr. L. R. B. Elton. Pp. xi+286. (London: Sir Isaac Pitman and Sons, Ltd., 1959.) 40*s*. net.

Soviet Reviews of Nuclear Science on the 40th Anniversary of the October Revolution

(Being Vol. 3, No. 11 of *Atomnaya Energiya*, November, 1957.) (International Series of Monographs on Nuclear Energy. Division 2: Nuclear Physics, Vol. 3.) Pp. v+110. (London and New York: Pergamon Press, 1959.) 30*s*. net.

Fundamental Aspects of Reactor Shielding

By Dr. Herbert Goldstein. Pp. xvi+416. (London and New York: Pergamon Press, 1959.) 66*s*. 6*d*. net.

Fundamentals of Nuclear Energy and Power Reactors

By Henry Jacobowitz. Pp. 118. (New York: John F. Rider Publisher, Inc.; London: Chapman and Hall, Ltd., 1959.) 2.95 dollars; 24*s*.

An Introduction to Thermonuclear Research

A Series of Lectures given in 1955. By Albert Simon. (International Series of Monographs on Nuclear Energy. Division 14: Plasma Physics and Thermonuclear Research, Vol. 1.) Pp. ix+182. (London and New York: Pergamon Press, 1959.) 35*s*. net.

THE six books listed represent a mixed bag. "Lectures on Nuclear Theory" by Landau has appeared before and is now available in book form, surprisingly without the name of the translator. The lectures are extremely clearly presented: they were, in fact, originally delivered to experimental physicists and the authors have been at great pains to describe most carefully the physical pictures they analyse mathematically, and to state the limit to which modern experimental results allow theory to go. What we have learned about forces between nucleons from scattering experiments occupies half of the book. Then follows a detailed statement of structure of light and heavy nuclei and a review of neutron and meson interaction with nuclei. A delightful book, not only for students but also for all physicists who enjoy clear exposition. Dr. Elton's "Introductory Nuclear Theory" covers the same ground in much greater detail and with more extensive mathematical proof. It is a text-book for the theoretical physicist of final honours and postgraduate standard and as such is an extremely thorough presentation based, as Dr. Elton describes in his preface, on the phenomenological approach to the nuclear data emanating from the large machines and cosmic ray plates.

The "Soviet Reviews of Nuclear Science" is rather old: the papers were prepared to mark the 40th anniversary of the October Revolution. Pontecorvo writes "In the glorious fortieth year of the October . . ."! The four papers on nuclear power in the U.S.S.R. are completely superseded by the Geneva 1958 papers and were not worth reprinting at this date: this might also be true of the two survey articles on radioisotopes and radiochemistry. It seems rather pointless to translate review articles; reviews on most subjects are prepared in many countries and the review here translated on interaction of slow neutrons with nuclei is based on world literature, and again all the material can be found in the Geneva papers. There remains one long article on research with the 6-metre synchro-cyclotron, a review article of the Soviet paper with no reference to foreign work. However, this is a valuable summary of experimental results and is well illustrated.

Two books on reactors stand at the top and bottom of their class. Goldstein's authoritative work on "Fundamental Aspects of Reactor Shielding" comes from the Division of Reactor Development of the Atomic Energy Commission, and clearly illustrates the great part the research physicist has to play in nuclear engineering. Reactor shielding is an expensive fraction of nuclear power costs, and "the proper design for a given reactor shield should start from first principles". This book deals very thoroughly with first principles, neutron and gamma-ray attenuation in isotopic and discontinuous media, and compares theory with the experimental results achieved over the past few years with the shielding facilities built on to the Oak Ridge reactor, the graphite and the original water-moderated 'pool'-type reactor. These facilities and the instrumentation for shield testing are well described; the latter illustrates how alert the experimenter must be in this subject if measurements in high and low fluxes are to be reasonably accurate. The book opens with a careful discussion of the biological effects of radiation. The reader notes the frequent references to results reported in Oak Ridge and other laboratory reports, apparently not submitted to any of the learned societies or established journals. Many were originally classified and appear now with references declassified or even still classified: the abstracting journals will be presented with a serious problem if this practice continues. The book will be essential to all engaged on shielding studies, and the references to original work are comprehensive.

One wonders for whom "Fundamentals of Nuclear Energy and Power Reactors" has been written, for it is neither comprehensive nor superficially accurate; but it sets out to attract the general interested public and the members of the atomic industry. For the latter, it does not even mention the important developments abroad, though the book does not state that it is merely reviewing the American scene. It dismisses the graphite-moderated natural uranium reactors as obsolescent, in spite of more than 4,000 MW. of such reactors under construction, and makes no reference to the Russian reactor incorporating the superheating of steam by nuclear energy. The book is well illustrated, but alas contains much slang—do we get "mileage" out of fuel? I would commend the author to Dr. Goldstein's impeccable style.

The appearance of "An Introduction to Thermonuclear Research" in 1959 in its present format is a little disappointing; the Geneva 1958 papers disclosed so much more information than can be found in this book. The preface states that the book is based on lectures of 1955 to which some 1956 information has been added: the basic science in the book is worthy of inclusion although it can all be found elsewhere, but the long catalogue of the American devices in which plasma studies have been made will be nearly meaningless to scientists not working in the field and is outdated information for those who are. The book makes no reference to work in other countries as it closes in 1956: the reviews in the Geneva 1958 papers (Volume 31) will repay study better than this little volume. T. E. Allibone

CONSTANTS GALORE

The Physico-chemical Constants of Binary Systems in Concentrated Solutions

By Prof. Jean Timmermans. Vol. 1: Two Organic Compounds (without Hydroxyl Derivatives). Pp. xiii+1259. Vol. 2: Two Organic Compounds (at least one a Hydroxyl Derivative). Pp. xi+1272. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 218*s*. a volume.

These two books are part of a series of four volumes prepared as a result of a systematic literature survey carried out between 1910 and 1957. Unfortunately no list of the journals abstracted is given. The National Science Foundation of Washington, D.C., gave a substantial grant to enable Dr. Lewin to have the records typewritten so that the publishers could produce the books by offset printing. The pages contain an immense amount of information, but they are disfigured by lack of uniformity; for example, the negative sign sometimes appears before every entry in a table but in other places it appears before the first entry only although it is applicable to all the entries. The arrangement of the mixtures follows a scheme devised by the author, but as the index and bibliography are reserved for volume 4 search for information can only be made by turning pages. Some assistance is afforded by the pair of names boldly printed at the head of each page and these usually refer to a mixture occurring somewhere upon that page, but unfortunately in some instances (for example, Volume 1, pp. 765 and 1191) the names do not coincide with the mixtures listed.

Once a mixture is located the existing data are found arranged in the following order: heterogeneous equilibria (critical constants, saturated vapour pressure curve, boiling curve, azeotropes, composition of liquid and vapour in co-existing phases, densities and rectilinear diameters, composition of the two liquid phases, critical solution point, freezing and melting curve, eutectic and transition points, equilibria of condensed phases under high pressure); properties of phases, first for the gas, then for the liquid and finally for mixed crystals (density, coefficient of expansion, compressibility, viscosity, surface tension, refractive index, optical dispersion, dielectric constant, electrical conductivity, optical rotating power, magnetic rotation, magnetic susceptibility); thermal constants (specific heat, heat of solution or mixing, heat of vaporization and fusion, thermal conductivity). All numerical data have been taken directly from the original papers and values read from graphs are indicated. A list of symbols and abbreviations is presented at the front and back of each volume, but the symbols do not conform to modern usage. In particular, a reader should note that the old *Q* convention for heat quantities is adopted.

The words "Systems in Concentrated Solutions" are unusual as applied to binary mixtures because a solution that is concentrated with respect to one component is dilute with respect to the other. The author says, however, that concentrations between 10 and 90 weight per cent are tabulated, although the tables do in fact contain some figures outside this range. The percentages recorded appear to refer to the concentration of the second named component, although this is not stated in the list of symbols or in the instructions to users.

The selection of values is not critical and many of them were originally published long before 1910. Thus, some systems are covered at great length and many discordant values for certain constants are recorded. Timmermans discusses in the preface to Vol. 2 the reasons for these divergent values and suggests that they arise in part because insufficient care has been taken by some authors in the purification of specimens. If the purity of the samples is employed as a criterion of worth, much of the recorded data has little value.

These volumes are expensive, but they provide such a useful guide to published data, particularly for a worker conversant with the substances under investigation, that many libraries will wish to acquire these books. E. F. G. Herington

THE BRAIN IN RESPONSE

Person Perception and Interpersonal Behavior

Edited by Renato Tagiuri and Luigi Petrullo. Pp. xx+390. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1958.) 60*s*. net.

The Problems of Perception

By R. J. Hirst. (The Muirhead Library of Philosophy.) Pp. 330. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Company, 1959.) 30*s*. net.

In recent years, an increasing degree of attention has been devoted to the study of what is called 'person perception' or 'social perception'. The book "Person Perception and Interpersonal Behavior" consists of a symposium of 23 papers on these subjects. As is usual with such symposia, the relationship between the topics discussed in the various papers is often not clear. The value of the book, especially to the general reader, would have been greatly increased by the addition of some attempt to sum up and derive general conclusions from the papers as a whole. The reader will find all the more difficulty in doing this for himself because the terms 'person perception' and 'social perception' are used by different authors to include several different processes the inter-relationship of which has never been worked out. It is generally accepted that we not only perceive, more or less objectively, the physical characteristics and actions of other people; we also infer from these perceptions personal characteristics such as feelings of liking and disliking, motives and intentions, social status and background, etc. The original perceptions, and still more the inferences derived from them, are enormously affected by our own feelings, motives and social relationships to other people, and by the way in which we react to them. Sometimes the effects are relatively consistent, but often they vary according to the particular situation. Included in this book are studies by Ittelson and Slack and by Secord of the factors which affect the perception of faces and other physical characteristics. But there are many more studies of the inferences and judgments made about the personality characteristics of others, and how these vary with the personality and likes and dislikes of the judge, and with the social situation. There is an interesting paper by Jones and Thibaut on how people interact in a variety of social situations; and several papers discussing the reasons for one person being attracted by another —whether because the second fulfils the needs of the first, or because he appears to possess the same personality characteristics or interests. A final paper by Cronbach demonstrates the present limitations on the accurate analysis of these judgments, feelings and interactions, and the factors which determine them.

Little or no attempt appears to have been made to discover what is actually perceived, or what are the significant aspects of behaviour and expression which we observe in others; nor how these perceptions lead to the inferences and judgments described above. Granted this is a task of great difficulty and complexity, but it is hard to see how any real understanding of 'person perception' can be gained until some systematic analysis has been made of the psychological processes involved and their interrelationship. Thus, although the psychologist with some knowledge of these topics can find many points of interest in the papers included in this book, the general reader will be liable to become hopelessly confused by the mass of apparently unrelated hypotheses which are frequently expressed in bewilderingly esoteric language.

"The Problems of Perception" provides a philosophical study of the nature of perception in general. It presents a critical examination of the various philosophical theories as to the nature of perception, together with the author's own theory, which is more in accordance with present-day knowledge of the physiology and psychology of perception. The book should be of real interest and value not only to philosophers but also to psychologists and to the general reader. It is clearly written, and necessitates little previous knowledge of philosophy or of technical language.

The author demonstrates convincingly that earlier theories have never provided a satisfactory explanation for the high degree of veridicality of our perceptions on one hand, in spite of the restricted nature of the physiological information conveyed by the sensory nerves to the brain; and on the other hand, the modifications, errors and individual differences in perception which undoubtedly occur, and the apparently perceptual nature of hallucinations which arise in default of external stimulation. His own theory appears to provide a much better explanation. It makes due allowance both for the convincing objectivity and external reference in our perceptions of the surrounding world, and also for the undoubted influence on them of subjective factors; though whether in fact perception of external objects as such is inherent and arises even in early infancy is not perhaps as certain as he would have it to be.

There is one matter which his theory, depending as it does on the concept of 'perceptual consciousness', does not appear to cover adequately—namely, the unconscious perceptions which seem so frequently to guide our habitual and automatic actions. Psychological study of this type of perception, and of perception at the margin of consciousness, is only just beginning. But when rather more is known of these perceptions, philosophical theory may require further extension to cover them. M. D. VERNON

STRUCTURE AND GROWTH OF PLANT CELL-WALLS

The Plant Cell-Wall

By Prof. Pieter A. Roelofsen. (Encyclopedia of Plant Anatomy, Band 3, Teil 4.) Pp. vii+335+68 plates. (Berlin-Nikolassee: Gebrüder Borntraeger, 1959.) n.p.

IN this age, when man-made fibres are so very much in the news, it is a salutory lesson to recall that naturally occurring fibres were in existence upon the Earth long before man, and that they continue to be manufactured by living organisms with a perfection and in a complexity which man still cannot match. Such a lesson is given by Roelofsen's book for fibres made by plants.

The structure of the plant cell-wall has been under constant review ever since its observation by Robert Hooke in 1664, first by light microscopy then, largely after the influence of Carl v. Naegeli, by polarization microscopy, then by X-ray diffraction analysis and now by all these methods supplemented by electron microscopy. Up to this newest development, the study was in the hands of the relatively few botanists with the requisite knowledge of physical principles and training in physical techniques. The electron microscope has, however, thrown the field wide open, and this, coupled with the growing realization of the importance, both academic and technological, of the cell-wall, has led, during the past ten years, to a vast increase in the number of laboratories actively engaged in research and therefore in the number, range and variety of published papers. Prof. Roelofsen himself returned to this study some ten years ago after an absence of twenty years and has during this period of rapid expansion already established himself as an authority in this difficult field.

This book, in my opinion in many ways the best which has yet appeared on this subject, can only enhance Prof. Roelofsen's reputation. The deep appreciation of the powers of electron microscopy which all workers feel make it dangerously easy to fall into the trap of ignoring older work by older methods. This trap Roelofsen conscientiously avoids. It is, indeed, one of the most admirable features of his book that each topic he takes up is dealt with historically, in the sense that what may be called the classical key investigations are reviewed in detail and the later work is always placed in its proper context against this general background. To my certain knowledge very few lines of investigation are omitted and very few papers of lasting importance fail to receive due appreciation. Perhaps the biosynthesis, particularly of cellulose, does not have the attention it appears to merit in view of its importance in questions of wall growth, but this may be due to shortage of space.

The book is divided broadly into two sections. The first, in eight subsections covering 100 pages, deals with the nature, occurrence, chemical and physical properties and biosynthesis of the various components of plant cell-walls. This includes treatment not only of the 'standard' components—celluloses, hemicelluloses, polysaccharides, lignin, and chitin but also of low molecular weight polyoses, cutin, suberin and rarer compounds such as phytomelane. There is in these pages much useful information which, so far as I am aware, has not hitherto been gathered together in one volume.

The second, larger, section, in four subsections covering more than 200 pages, deals with the physical methods of investigation and a wide review, surprisingly detailed and comprehensive in view of the comparatively small space available, of wall structure in higher plants, in algae and in fungi. The treatment of the physical methods is, wisely, not detailed; even making allowances for difficulties in translation the text in various places makes it clear that Prof. Roelofsen is himself not a physicist and he refers his readers to other texts. There is, however, sufficient here to enable the intelligent reader to make a critical appraisal of the subsequent statements. As to these, it is not an exaggeration to say that the facts available up to the time of going to press are all here, clearly stated and documented by reference to the appropriate literature. Equally, both the older and the current theories concerning mechanisms of orientation and of surface growth of the primary walls in higher plants are dealt with, though here the treatment is not, perhaps, so comprehensive. Prof. Roelofsen is himself the author of a theory of growth which is very much to the fore at this moment and it is natural, and welcome, that he should pay to this a good deal of attention in his book. I find much in the hypotheses formulated in this part of the book to which I could not lend support—the author, for example, seems to repeat an older error in confusing *stress* with *strain* and this leads to a peculiar paragraph on p. 175 (the first paragraph in 228231)—but this again is natural and no criticism; the exposition is challenging and provocative and what more can be expected of hypotheses? It is perhaps unfortunate that the arrangement of the book precludes a unified consideration of growth both in higher and lower plants.

It is, however, a happy feature of his book that Prof. Roelofsen never hesitates to express his own opinion, for this builds what might have been to the general reader a dreary review into a well-knit whole, a fascinating easily read story.

The book is translated from an original manuscript in Dutch, and both the author and Prof. C. E. B. Bremerkamp, who assisted in the translation, are to be congratulated that it reads so easily. There are flaws in the English, but these are nowhere such as to mislead the reader, even the use of the word "bruto" on p. 173. The book is copiously illustrated by electron micrographs, all of them drawn from the published papers of the writers whose work is discussed; these are necessarily of uneven quality since some are drawn from earlier work and some refer to difficult material. There is a comprehensive bibliography of some 815 references, and both subject and author indexes as well as indexes of botanical and zoological names.

This is a book which no botanist—nor any technologist interested in cellulose fibres—can afford to ignore. It is a first-class reference book for the specialist, a fascinating unfolding story of research down the years for general readers, and an instructive, thought-provoking book for advanced students. To all these, it is recommended in the warmest terms.

R. D. PRESTON

A Biochemical Approach to Pathology

By M. J. R. Dawkins and Dr. K. R. Rees. Pp. vii+128. (London: Edward Arnold (Publishers), Ltd., 1959.) 18*s*. net.

As the advance of knowledge invades the old border-lines between the sciences, pathology becomes increasingly concerned with the chemistry of the cell, considered in topographical detail as an organized system of mainly enzymatically promoted reactions. Morbid states formerly described only in anatomical and histological terms have now to be interpreted in terms of chemical derangement in cytoplasm, microsome or other specified site. The first assertion is the justification of this book; the second describes the approach taken by its authors. Within the confines of 120 pages, two disciplines are bridged with an adequacy necessarily dependent on wise selection and enforced abbreviation. The authors have succeeded so well in combating these limitations that there is ground for some regret that more space could not be made available to them. Whereas pathologists may find difficulty with the assumption of extensive prior reading in chemistry, biochemical readers are less severely taxed in pathology, but both are aided by a wisely chosen short guide to further reading. Some of the present frontiers of knowledge are indicated in a stimulating manner.

The unfortunate tendency to write in initials (RNA, DPN and too many others) is strongly maintained without benefit of a glossary and detracts from an otherwise eminently readable text, while important substances such as adenylic acid appear only by name, assuming the glib role of shibboleth.

For a first edition, this well-produced volume is commendably free from errors, excepting the tri-valent carbon shown in the structure of bilirubin (p. 40) and the confusion of β-amino-α-naphthol with *o*-aminophenol (p. 115). R. W. R. Baker

Proceedings of the Second United Nations International Conference on the Peaceful Uses of Atomic Energy held in Geneva, 1 September—13 September 1958

Vol. 2: Survey of Raw Material Resources. Pp. x+843. (Geneva: United Nations; London: H. M. Stationery Office, 1958.) 80 Swiss francs; 132*s*.; 18.50 dollars.

The geological discussions at the second Geneva conference on atomic energy, reported in this volume, had a much more international character than those at the first conference in 1955. At the latter, the delegation from the United States contributed 85 out of 125 papers on geology and prospecting, Great Britain and Brazil each produced four contributions, and the remaining 32 works came from 22 different countries. In 1958 only 30 papers out of 84 were of American origin and there was a much larger presentation from other lands, notably from the U.S.S.R., France, Canada, South Africa and India. Discussions were also more open, for as a direct consequence of the Free World's glut of uranium no aspect of the economic geology of radioactive ores is now secret in the West—although information on the location and output of domestic deposits is still 'classified' in the U.S.S.R. The radiogeological studies printed in this "Survey of Raw Material Resources" range widely over the diverse fields of economic geology, prospecting, geochronology, uranium mineralogy, and geochemistry; and they make up what is undoubtedly the most comprehensive assemblage of new information on radioactive mineralization that has ever been brought together. C. F. Davidson

Sechzig Jahre Medizinische Radiologie

Probleme und Empirie. Von Prof. Hans R. Schinz. Pp. 275. (Stuttgart: Georg Thieme Verlag, 1959.) 19·50 D.M.

This book is a historical document written by Prof. H. R. Schinz of Zurich on the occasion of the Ninth International Congress of Radiology in 1959. It covers 60 years of medical radiology from the date of discovery of X-rays up to the present. The first section of the book deals with the discovery of X-rays by Rontgen. This is preceded by a short annotation leading up to this momentous achievement. The discovery of uranium and radium and their radioactive properties by Becquerel and the Curies is dealt with in a similar way, and so is the fundamental early work on nuclear and radiation physics by Rutherford and his co-workers. This first chapter covers all the important milestones in experimental and theoretical physics up to the 1950's, listing all the great names connected with this work throughout the world.

In the second section there is a short historical note on technical achievements and the development of X-ray apparatus. The main section of the book deals with the medical aspects of radiology, in particular radiobiology, X-ray diagnosis and radiation therapy and their advances during the past 60 years. Finally, some of the original papers of the early days of radiation physics by Rontgen, Rutherford, Becquerel, the Curies, Hahn and Strassmann are appended.

This book is a useful historical review of the past 60 years, mentioning all the outstanding workers in the field: it also contains a number of interesting historical photographs and charts referring to the very early fundamental work. R. E. Steiner

How Animals Move

By Sir James Gray. (The Royal Institution Christmas Lectures 1951.) Pp. 144. (Pelican Book A454.) (Harmondsworth, Mddx.: Penguin Books, Ltd., 1959.) 3*s*. 6*d*.

In 1951, Sir James Gray gave six Christmas lectures to a young audience at the Royal Institution. His task was ". . . to illustrate the more striking features of animal locomotion without assuming previous biological knowledge". The lectures, together with many admirable illustrations and revealing photographs, were published by the Cambridge University Press in 1953. It is good that the book will now be available to many more readers, who will discover an absorbing subject treated in clear and direct English. Young naturalists (and older ones) will learn that the movements of animals can be illusory or impossible to follow without suitable recording devices. Correct observations require much circumspection (for example, anglers should not be misled as to the speed of a hooked fish by the scream of a reel). Lastly, the reader, who could be an artist just as well as someone with an interest in biology, will find a lucid analysis of the living mechanics of locomotion, one that parallels the natural ease of the animals themselves. N. B. Marshall

PRIMARY STRUCTURE OF THE PROTEIN OF TOBACCO MOSAIC VIRUS

By F. A. ANDERER, H. UHLIG, E. WEBER and Prof. G. SCHRAMM
Max-Planck-Institut fur Virusforschung, Tubingen

THE tobacco mosaic virus, in spite of its limited economic importance, has continually played a noteworthy part in virology. It was the first infectious agent to be classified as a virus by the pioneering experiments of Iwanowski (1892) and Beijerinck (1898). It was also the first virus to be isolated in a pure paracrystalline state by Stanley in 1935 and to be identified as a nucleoprotein by Bawden and Pirie. The ribonucleic acid was isolated from tobacco mosaic virus and proved to be infectious by Gierer and Schramm[1] and by Fraenkel-Conrat and Singer[2]. Later, this experiment was successfully repeated with many other plant and animal viruses containing ribonucleic acid[3,4]. Thus we are led to the concept that ribonucleic acid is the genetic material of these viruses and determines the structure of the virus protein. Due to intense study in various laboratories the physical and chemical structure of tobacco mosaic virus is the best known of all viruses. Unfortunately, tobacco mosaic virus is less suitable for genetic studies; the bioassay is of limited sensitivity, single cells in culture media are not infected at a satisfactory rate, and combinations between different strains are not observed, making gene mapping impossible. But one can assume that tobacco mosaic virus will remain a favourite object for studies of the structural interrelationship between ribonucleic acid and its specific protein. One important step in this direction is the precise knowledge of the sequence of amino-acids in the protein.

Studies concerning the tobacco mosaic virus protein began shortly after its isolation, but the further progress, which depended upon the development of methods in protein chemistry, was slow. Using methods which now appear primeval, W. M. Stanley[5] and G. Schramm and H. Müller[6] isolated certain amino-acids by fractional crystallization. At that time the task of finding the complete amino-acid sequence in a particle with a molecular weight of 40×10^6 seemed quite hopeless. A solution of this problem seemed more possible after it was discovered that the virus protein consists of a great number of sub-units which appear identical in their physical and serological properties[7]. In weak alkaline solutions a dissociation into protein sub-units of a molecular weight of 90–100,000 was observed. This protein was called *A*-protein[8]. Later the virus protein could be dissociated further to the smallest sub-unit, which has a molecular weight of 17,500[9-11]. By re-aggregation of the *A*-protein[12] rod-like particles could be obtained which had a structure similar to the virus itself.

After development of chromatographical methods, especially paper chromatography, and the stimulating success of Sanger in the complete analysis of insulin (1949–55), the elucidation of the protein structure became experimentally possible. Using a combination of columns consisting of organic and inorganic adsorbents certain groups of amino-acids were estimated[13]. The first complete analysis was reported by Knight[14], who applied microbiological methods. More precise analyses became possible through the development of more reliable methods for the separation and quantitative estimation of amino-acids by ion exchange columns, a method for which we are indebted to Stein and Moore *et al.*

Further work of this group produced the automatic amino-acid analyser[15], without which the results described in this paper would have been virtually impossible. Cation-exchange columns have been extensively used for the separation and preparation of peptides. For the analyses of ribonuclease, Hirs, Stein and Moore[16] employed 'Dowex 50'. Braunitzer *et al.*[17] introduced an important modification by using the anion exchanger 'Dowex 1', with which the separation of peptides, particularly those containing basic amino-acids, was far more satisfactory. Using volatile buffer solutions containing pyridine and collidine, the laborious desalting process was avoided.

Before the analysis of the amino-acid sequence in a protein, the amino-acid composition and the number and nature of the terminal groups must be known. This is the most reliable way to prove the homogeneity of the material. The C-terminal group in the tobacco mosaic virus protein was identified by Harris and Knight[18] with carboxypeptidase. They found one mole of threonin per 17,300 gm. of tobacco mosaic virus. This value was confirmed by hydrazinolysis[19]. By short treatment with hydrazine the C-terminal peptide Pro-Ala-Thr was isolated[20,21], whereas by enzymatic hydrolysis Niu and Fraenkel-Conrat[22] determined the sequence of the last six amino-acids to be Thr-Ser-Gly-Pro-Ala-Thr. Since the virus does not contain a free terminal amino-group[23] the determination of the N-terminal configuration was more difficult. After treatment of the virus with trichloroacetic acid or hydroxylamine the imino-group of proline was released[24]. Therefore it was first assumed that proline, blocked by a labile substituent, was terminal. Later it was found that the Asp-Pro-bond inside the peptide chain is particularly labile and Pro could therefore not be N-terminal[25]. The correct N-terminal groups were found to be N-Acetyl-Ser-Tyr by Narita[26]. It was then clear that tobacco mosaic virus protein consists of about 2,200 peptide chains with the same terminal sequences.

It was then conceivable that the location of the other amino-acid residues in these peptide chains might also be identical. Therefore sequence studies were begun in several laboratories. Tryptic digestion of the protein was the first step, since the reaction of trypsin is quite specific, affecting only the carboxylic groups of the basic amino-acids. Because only a relatively small number of peptides is expected in the digestion mixture, the separation of these peptides ordinarily is not too difficult. In the Virus Laboratory in Berkeley a partial separation of the tryptic peptides, chiefly by counter-current distribution, was achieved and the sequence and composition of several of these tryptic peptides have already been described[27]. Wittmann and Braunitzer[28] separated all the tryptic peptides using 'Dowex-1' anion exchangers. They found twelve different peptides, accounting for all of the amino-acids. For the first time the amino-acid content of tobacco mosaic virus could be calculated exactly by summing up the composition of the peptides. According to these authors the peptide chain consists of 157 amino-acids and has a molecular weight of 17,400, which is in good agreement with the terminal group determinations and with physical, chemical and X-ray studies[9-11,18,19,21,22]. Furthermore, the N-terminal groups of eleven of these peptides were identified and the arrangement of several of these peptides inside the chain was elaborated by comparison of the tryptic peptides of different strains of tobacco mosaic virus[30].

Our own studies also began with the tryptic hydrolysis of the protein separated from the ribonucleic acid by extraction with phenol or acetic acid. In early experiments the separation of the peptide was tried by dinitrophenylation and subsequent paper electrophoresis and paper chromatography. The results were very unsatisfactory. Later we turned to column chromatography with the cation exchange resin 'Dowex 50' as the adsorbent. Most of the peaks arising in the effluent were mixtures of different peptides which had to be separated further by high-voltage electrophoresis and paper chromatography. Much better results were obtained with the anion exchange resin 'Dowex-1' according to the technique of Wittmann and Braunitzer. Only a few boundaries contained more than one peptide. While preparing the digest for column chromatography, we found a peptide insoluble in acidic solutions. This peptide was called *TU* (*tryptisch, unloslich*). A similar peptide was observed by Gish *et al.*[27] and by Ramachandran *et al.*[27] and designated as I-peptide (insoluble). The *TU* peptide was purified by several precipitations between *p*H 3 and 5 and by paper chromatography. It contains 41 amino-acids and has the same composition as the peptide No. XII of Wittmann and Braunitzer. The N-terminal group is N-Acetyl-Ser-Tyr. Therefore *TU* is the N-terminal peptide of the whole chain. The sequence of the amino-acids in this peptide is described by Anderer, Weber and Uhlig[31]. Besides the *TU* peptide eleven other tryptic peptides were found. The amino-acid compositions of all were determined with the automatic amino-acid analyser. The N- and C-terminal groups were identified, and the sequential structure elaborated so far as necessary to correlate with peptic and chymotryptic peptides described below. In Table 1 the amino-acid composition and the terminal groups of the twelve tryptic peptides are indicated in the order in which they occur in the peptide chain. The analytical data agree exactly with those of Wittmann and Braunitzer. Summing up the tryptic peptides, the molar ratios of the amino-acids in the total chain can be calculated. In the order of their frequency we obtain the following formula:

$$\mathrm{Asp_{18}Glu_{16}Ser_{16}Thr_{16}Ala_{14}Val_{14}Leu_{12}Arg_{11}Pro_{8}Ileu_{9}}$$
$$\mathrm{Phe_{8}Gly_{6}Tyr_{4}Try_{3}Lys_{2}Cys_{1}}$$

Analysis of the total protein confirmed these ratios. The time of hydrolysis for the analyses was varied between 17 and 60 hr. and the values obtained in five experiments were extrapolated to zero time.

In order to find the sequence of the tryptic peptides the protein was degraded with chymotrypsin and pepsin. Attention was primarily directed to peptic and chymotryptic peptides which formed bridges between two tryptic peptides (bridge peptides). Since all tryptic peptides end with Arg or Lys the bridge peptides must contain these basic amino-acids. In certain experiments only the Arg-containing peptides were selected by the Sakaguchi reaction. The peptides were separated on columns of 'Dowex-50' or 'Dowex-1'. Further purification was achieved by paper chromatography of the dinitrophenyl derivatives. In this way about 80 different peptides were isolated and their amino-acid composition and sequence determined. The C-terminal sequence was studied by hydrolysis with carboxypeptidase *A*. If the terminal group was Arg or Lys, a mixture of carboxypeptidase *A* and *B* was employed. The N-terminal groups were mainly identified by the dinitrophenyl method. In order to find the second residue the terminal dinitrophenyl amino-acid was removed by hydrogenation according to the method of Justisz[32] or of Uhlig[33], and the dinitrophenylation was repeated. Occasionally the Edman degradation was also applied. Further insight into the N-terminal configuration was obtained by degradation with aminopeptidase. Sequence analysis was completed by partial hydrolysis with 0·1 *N* or 12 *N* hydrochloric acid or further digestion with chymotrypsin or pepsin. Of the 80 peptides only the 22 bridge peptides are given in Table 2. We have been able to isolate all bridges which were necessary to connect the twelve tryptic peptides in an unequivocal way and thus to deduce the structure of the entire chain of 157 amino-acids. The derivation of the formula can be understood by comparison of Tables 1 and 2 with Fig. 1.

The peptides I–III (Table 2) contain the C-terminal sequence of the *TU* peptide followed by Thr. Since only one tryptic peptide exists beginning with Thr, this must be adjacent to the *TU* peptide. The peptides IV–VII contain the C-terminal sequence of the Thr-peptide and the N-terminal sequence of the $\mathrm{GluNH_2}$-peptide. Therefore, the $\mathrm{GluNH_2}$-peptide occupies the positions 47–61. This $\mathrm{GluNH_2}$-peptide contains one Lys residue which is resistant to trypsin. The peptides VIII–X demonstrate the sequence adjacent to this first Lys residue. The junction with the next peptide beginning with Phe and ending with Lys is given by the peptides XI and XII. The locations of the tripeptide Val-Tyr-Arg and the following peptide beginning with Tyr are deduced from the peptides XIII–XV. The peptic peptide XVI shows the location of the dipeptide $\mathrm{AspNH_2}$-Arg and the following Ileu-peptide. This is joined to the next peptide by an Arg-Arg-bond (see peptides XVII and XVIII). The carboxylic group of the second Arg residue is attacked slowly by trypsin, thus the tryptic peptide position 112–121 contains Arg as the N-ter-

Fig. 1. Sequence of amino-acids in the protein of tobacco mosaic virus

minal group. This is followed by the tryptic peptide beginning with Ser-Ala, and the location of the last two peptides is given by the peptides XX–XXII. Additional evidence for the C-terminal position of the Ser-peptide (141–157) is that its terminal sequence Pro-Ala-Thr is identical with that found to be the C-terminal sequence of the tobacco mosaic virus protein. Only the relative positions of the residues 26–28 and 98–102, which are set in parentheses, need reinvestigation. The amidation of the Glu and Asp residues marked with an asterisk has not been determined. Apart from this couple of uncertainties a good picture of this large peptide is obtained.

Discussing the reliability of these results we have to keep in mind the following facts. The amino-acid composition of the tryptic peptides agrees completely with that found by Wittmann and Braunitzer and the sequence of the first five tryptic peptides has also been confirmed by Wittmann[30] in quite a different way. Some of the tryptic peptides are also described by the Berkeley group. Errors are further restricted because all the positions are covered by several degradation products obtained from the total protein or the isolated tryptic peptides. The complete list of all degradation peptides for the positions 1–41 has already been published[31] and that for the other positions will be published elsewhere. In Fig. 1 the points of cleavage by trypsin, chymotrypsin, and pepsin are indicated to give a general idea of the number of peptides which were laboriously separated and characterized.

Asp* = Asp or AspNH$_2$; Glu* = Glu or GluNH$_2$

The careful analysis of larger peptide chains furnishes several kinds of information. Proteins have specific functions and their biosynthesis is under genetic control. Therefore we cannot expect a random sequence of amino-acids. The accumulation of Ser in the first 15 and in the last 17 positions is striking. These terminal parts, comprising 20 per cent of the molecule, contain 11 of the 16 Ser residues. Of course, more data on other proteins must be collected before any conclusion can be drawn about regularities in the combinations of individual amino-acids.

Furthermore the results reveal information about the specificity of the proteinases. Trypsin was strictly specific for the basic amino-acids; only the Lys residue in position 53 was resistant, perhaps due to the adjacent Pro, and the Arg residue in position 112 was inhibited. A Lys residue resistant to trypsin was also found in ribonuclease[32]. Chymotrypsin liberated the carboxylic group of Phe, Tyr, Try, and Leu, and less frequently that of GluNH$_2$ (three times) and of Thr (twice). Pepsin reacts rather unspecifically. It frequently affects the carboxylic or the amino group of Phe, Tyr, Leu, and Val. Ileu and GluNH$_2$ were also attacked in a few cases.

Since the ribonucleic acid of tobacco mosaic virus induces the synthesis of the protein a relationship between the sequences of the nucleotides and amino-acids, respectively, must be assumed. The ribonucleic acid contains about 6,000 nucleotides, that is, 40 nucleotides per 1 amino-acid residue in the protein. But are so many nucleotides actually required to bring one amino-acid into the right position? The determination of the entire sequence of 6,000 nucleotides is beyond the limits of our present experimental techniques. However, it may be possible to find certain correlations utilizing the inadequate technique at present available. By treatment with nitrous acid the nucleotide pattern of the ribonucleic acid can be altered *in vitro* and genetically stable mutants are produced[38,39]. The amino-acid sequences of these mutants should be compared with that of the normal strain to find out whether all mutants have undergone an alteration in the protein. If the ribonucleic acid produces other proteins, the genetical change could occur in these and the virus protein remains unaffected. In this case the ratio of nucleotides per amino-acid would be less than 40.

Fig. 1 shows only the primary structure of the tobacco mosaic virus protein. In the virus particles this chain is folded into an ordered secondary structure leading to protein sub-units. These protein sub-units are arranged in a helix which we call the tertiary structure. By denaturation the tertiary and secondary structures are destroyed, but under certain conditions the disordered protein can be re-naturated and re-aggregated to the original tertiary structure[36]. By reconstitution[37] with ribonucleic acid the tertiary structure is stabilized and the length of the protein helix is adapted to the length of the nucleotide chain. The importance of the amino-acid sequence in determining the internal structure of the tobacco mosaic virus particle is therefore evident.

RADIOACTIVE FALLOUT DURING 1959

By W. ANDERSON, R. E. BENTLEY, L. K. BURTON, J. O. CROOKALL
and C. A. GREATOREX

Physics Department, Institute of Cancer Research:
Royal Cancer Hospital, London

THE suspension of nuclear weapons testing from November 1958 until February 1960 has provided a useful period during which measurements of the relative abundance of different radionuclides in fallout material may be used to obtain some indication of the average age of this material and its atmospheric history. Further interest attaches to this period, for, as shown recently[1], the concentration of strontium-90 in rain falling over Great Britain rose sharply during the first half of 1959 to values substantially higher than those found for previous years. We have made measurements of the radiostrontium content of rain-water, sampled throughout 1959, and have also studied the variations in the concentration of certain short-lived fission products present in surface air during the same period. The results of these investigations are presented here and are discussed briefly in relation to current theories on the transport of fission products in the atmosphere.

Rain-water samples were collected at a site near Leatherhead, Surrey, using a polythene funnel and collecting bottle (funnel area for early samples, 325 sq. cm., and latterly, 1,320 sq. cm.). Radiostrontium determinations were made following well-established methods[2]. Samples of atmospheric dust were collected from surface air (of the order of 10^7 l.) at our laboratory at Sutton, Surrey, using a large two-stage electrostatic precipitator developed originally for

‡ Information not available.

air-cleansing purposes[3] (air-flow, 3,800 l./min.; efficiency of precipitation for methylene blue particles, 0·5μ mass median diameter, 80 per cent). These samples were studied by γ-scintillation spectrometry using a 100-channel analyser[4].

Samples collected during May–September 1959, that is, more than six months after the last reported nuclear weapons test in 1958, showed three prominent photopeaks. These peaks were at about 0·14, 0·50 and 0·75 MeV., which correspond to the γ-energies of cerium-144, (ruthenium-103 + rhodium-106) and (zirconium-95 + niobium-95) respectively. These are the main γ-emitting nuclides to be expected in a 6–18-month old mixture of fission products (Table 1). We have therefore assumed that these were the nuclides measured. A number of checks on the decay of their activity at various times after collection provided further confirmation of the validity of this assumption. The activities presented in Table 4 were computed from the areas under the photopeaks, using an experimentally determined calibration and making due allowance for the known branching ratios of the nuclides (Table 1, column 6). An estimate of the separate contributions of ruthenium-103 and rhodium-106 to the 0·51-MeV. peak was derived from two sets of measurements, one made shortly after collection and the other after a period covering several life-times of ruthenium-103.

Table 2. QUARTERLY CONCENTRATION (10^{-12} CURIE/LITRE) OF STRONTIUM-90 IN RAIN, 1959

Quarter:	1st	2nd	3rd	4th
Activity:	13·3	15·8	4·6	1·0

The average concentrations of strontium-90 found by us in rain-water collected over quarterly periods during 1959 are shown in Table 2. The values for the first two quarters are similar in magnitude to those reported recently[1], being approximately three times the average values found in the same periods of the previous four years[4]. The marked reduction of activity in the third and fourth quarters is illustrated in detail by monthly values from May onwards. These are plotted on a logarithmic scale against time in Fig. 1 (upper curve, μμc./l.).

It is well established[5] that, for long-range fallout of nuclear debris injected originally into the stratosphere, the principal mechanism of deposition is wash-out in rain-water after entry into the troposphere. The amount deposited by dry turbulent deposition is on the average only about 3 per cent of the total. In consequence, measurements of the specific activity of strontium-90 in rain, for average rainfall conditions, provide a useful guide to the

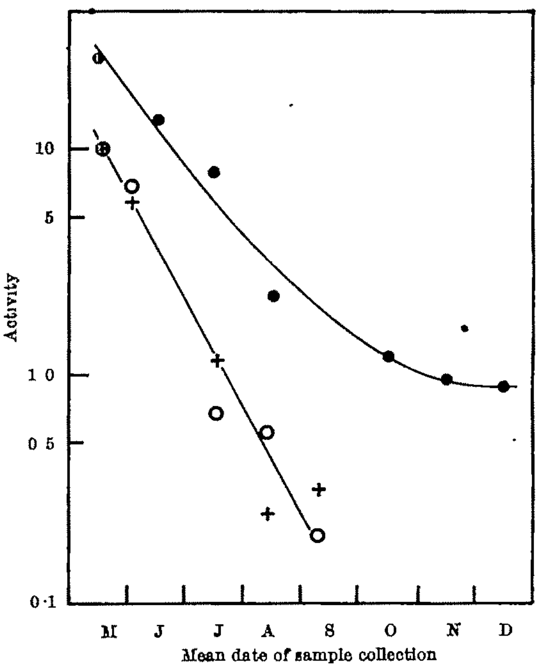

Fig. 1. Fission products in rain-water and air, 1959. ●, strontium-90 in rain; ○, rhodium-106 in air; + (zirconium-95 + niobium-95) in air

variations of activity in the lower atmosphere. It should be noted that the present monthly values for strontium-90 (Fig. 1) will include different fractional contributions from the dry deposition process, depending on the extent of departure from average conditions. Thus, from the known rainfall, and following the previous findings of Stewart *et al.*[5], it appears that for both May and June, which had comparatively low rainfalls, a dry deposition contribution of about 20 per cent should be allowed, compared with about 5 per cent for the other months, which had near average conditions. With due allowance for this factor, the results indicate that the concentration of strontium-90 in the lower atmosphere at the end of 1959 had fallen to one-twentieth of that present in May of the same year. Since the amount of radioactive decay of strontium-90 during this time would be negligible, the rapid fall in activity is clearly due to meteorological factors.

Table 3. STRONTIUM-89/STRONTIUM-90 RATIOS IN RAIN, 1959

Month:	May	June	July	August	Sept.	Oct.
^{89}Sr/^{90}Sr*	7·3	5·5	2·6	2·7	—	< 1·0

* ^{89}Sr ($T_{1/2}$ = 51 days) values calculated to mid-month.

The strontium-89/strontium-90 ratios of the rain-water (Table 3) provide a measure of the age of the strontium-90 being deposited during the summer of 1959. These ratios may be compared with the maximum values to be expected on the assumptions of (1) a strontium-89/strontium-90 ratio between 150 and 200 at the time of fission[6,7] and (2) an absence of weapons testing since November 1958. This comparison leads to the conclusion that on the average 70–85 per cent of the strontium-90 deposited during May–August 1959 was derived from fission processes which occurred during the autumn of 1958.

The results obtained for the concentrations of rhodium-106 and (zirconium-95 + niobium-95) in surface air are shown in Table 4. Compared with strontium-90, these radionuclides are short-lived, and during the period of the investigation a substantial radioactive decay of the atmospheric reservoir of these activities must have occurred. Using the known half-lives of these nuclides, the values in Table 4 may be re-scaled to eliminate the effect of the radioactive decay which occurred after the date of the first sample (May 17, 1959). The values adjusted in this way have been plotted on a logarithmic scale in arbitrary units against time (Fig. 1, lower curve). The two sets of results (rhodium-106 and zirconium-95 + niobium-95) have been normalized after equating the values for the first sample.

It is useful to compare the two curves plotted in Fig. 1, since both reflect changes in the radioactive particle content of the lower atmosphere. It should be noted, first of all, that our measurements relate to the atmosphere at a single site. However, since a prolonged period for atmospheric mixing elapsed between the last reported test in 1958 and the start of the present investigation, it is clear that the results represent conditions in the atmosphere over a comparatively wide area. This conclusion is underlined by the results of Stewart *et al.*[9] on the spread of nuclear dust clouds which were formed in the lower atmosphere from low-yield explosions. These workers showed that the lateral spread was virtually complete after a few weeks. Thereafter, apparently as the result of removal by deposition, the specific nuclear dust content of the air decreased exponentially, the 'half-life' for this process being approximately 22 days.

Table 4. CONCENTRATIONS (10^{-17} CURIE/LITRE) OF RHODIUM-106 AND (ZIRCONIUM-95 + NIOBIUM-95) IN AIR

Mean date of collection	Period of collection (days)	Rhodium-106*	(Zirconium-95 + niobium-95)
17. 5.59	4	17·0	180
2. 6.59	11	11·3	88
16. 7.59	16	1·02	11
12. 8.59	13	0·79	1·8
8. 9.59	11	0·25	1·7
31.12.59	21	0·26	0·25

* The ratio ruthenium-103/rhodium-106 for the sample at 17.5.59 was estimated to be 0·96.

Looking at Fig. 1, it will be seen that the values plotted for rhodium-106 and (zirconium-95 + niobium-95) lie fairly close to a straight line. This indicates that the concentration in air of fallout particles, which contained these nuclides, decreased exponentially during May–September 1959. The slope of the line shows that the 'half-life' of the removal process was approximately 20 days. The close similarity of this figure to that noted above for the removal of nuclear dust distributed in the lower atmosphere indicates that during June–September 1959 there were no substantial additions of relatively short-lived fission products to the lower atmosphere, either from a stratospheric reservoir, or from fresh weapons tests.

It will also be seen from Fig. 1 that the trend of the values of strontium-90 plotted for May–August 1959, is similar to that for the shorter-lived materials. The slope of the curve until August suggests a 'half-life' for removal of strontium-90 of between 30 and 40 days. Thereafter, the apparent rate of removal becomes greatly reduced and approaches zero at the end of the year. This is a clear indication that at the end of 1959 strontium-90 levels were being maintained by material from a stratospheric reservoir.

Taken together, the various lines of evidence presented above lead to the picture that about 75 per cent of the fallout of strontium-90 during the summer of 1959 was derived from a tropospheric reservoir built up during the early months of the year from material injected into the upper atmosphere in the autumn of 1958. Towards the end of 1959 it appears that the strontium-90 levels were then maintained largely by material descending from the stratosphere.

The average age of the strontium-90 in the stratospheric reservoir is a question of some interest. A comparison of the current trend of levels of relatively short-lived fission products with that of strontium-90 throws light on this question. It should be noted that the estimation of rhodium-106 in air was complicated at the end of 1959 by the fact that beryllium-7 produced by cosmic rays (γ line, 0·48 MeV.) was present in the air at about the same concentration as the fission-product nuclide (results in preparation). The values presented for rhodium-106 and (zirconium-95 + niobium-95) at December 1959 (Table 4) have been estimated by γ-spectrometry with due allowance for the effect of beryllium-7 on the rhodium-106 photopeak. After correction for radioactive decay, these December values suggest that the lower curve of Fig. 1 should be continued approximately parallel to the upper curve. This indicates that a large proportion of the fallout at the end of 1959 originated in fission processes which occurred during 1958.

During the years 1955–58 the trend of strontium-90 concentration in rain falling over Great Britain has shown fairly regular seasonal fluctuations, with maxima in the spring and minima in the autumn, the ratio of maximum to minimum being on the average 4 (ref. 1). These fluctuations have been interpreted by Stewart[5] as representing a seasonal variation in the rate of descent of stratospheric air, carrying long-lived fission products, into the troposphere. Martell[10] has advanced an alternative explanation suggesting that each maximum has been due to a rapid descent of activity in the spring from tests conducted at high latitudes in the autumn of the preceding year, the minimum values representing levels due to a more or less steady leak from a relatively persistent stratospheric reservoir. The results obtained by us for 1959 are clearly consistent with Martell's suggestion. It should be noted, however, that the strontium-90 maximum occurring in 1959 was notably higher than in previous years, and that the ratios strontium-89/strontium-90 do not exclude the possible occurrence of older stratospheric material at levels corresponding in magnitude to previous maxima. Consequently, it is not clear whether the increase in the maximum value for 1959, compared with previous maxima, reflects simply a quantitative difference, or whether two different upward fluctuations have been superimposed. In the latter case, it might be expected that the levels of activity would show a rise early in 1960. In this connexion it is interesting to record that the value found by us for the concentration of strontium-90 in rain collected during January 1960 was 1·7 μμc./l., which is approximately twice the value for December 1959. A preliminary analysis of our early 1960 dust samples also indicates an upward trend of rhodium-106 concentration in the air.

It may be useful to note that the nuclear test conducted on February 13, 1960, was carried out at a period when the activity already being deposited was apparently increasing. It is clear, therefore, that any upward trend in total atmospheric activity appearing after mid-February 1960 would not necessarily indicate a rise due to recent weapons testing. The effect of the French test (February 13) at the present site was to produce a pronounced, but transitory, rise of activity, comprising mainly short-lived fission products[11].

We wish to thank our colleague, Mr. R. P. Parker, for valuable information on the relative abundance of rhodium-106 and beryllium-7 in recent dust samples.

We are indebted to Prof. W. V. Mayneord, director of the Physics Department, Institute of Cancer Research: Royal Cancer Hospital, for his guidance and encouragement throughout this work.

DENSITY OF THE UPPER ATMOSPHERE AND ITS DEPENDENCE ON THE SUN, AS REVEALED BY SATELLITE ORBITS

By D. G. KING-HELE and MRS. D. M. C. WALKER

Royal Aircraft Establishment, Farnborough

IN previous articles in *Nature*[1-3] on upper-air density, a method of finding density from changes in the orbits of artificial satellites was presented, values of average density were obtained from fifteen satellites launched before September 1959, and the variation of density with latitude and season was discussed. The present article extends these results, giving revised values for air density at heights between 180 and 700 km. deduced from twenty-one satellites at dates up to March 1960, and describes two significant new features of the upper atmosphere which have now become apparent.

Method of Analysis

A satellite moving in an elliptic orbit encounters most air drag when it is closest to the Earth, and so the air density in this region, at heights near that of perigee, can be determined from the rate of contraction of the orbit, if the mass, size and shape of the satellite are known.

The method of analysis adopted here is the same as before[3]. The air density ρ is assumed to vary exponentially with height y, so that

$$\rho = \text{const.} \times \exp(-y/H) \qquad (1)$$

where H is a constant, the value of which is not known exactly[3]. It can then be shown[1] that, if H^* is the best estimate of H, the air density ρ^*, say, at a height $\tfrac{1}{2}H^*$ above perigee height is given in terms of the rate of change of orbital period, $\mathrm{d}T/\mathrm{d}t$, by the equation:

$$\rho^* = -\frac{0{\cdot}158}{\delta}\frac{\mathrm{d}T}{\mathrm{d}t}\sqrt{\frac{e}{aH^*}}\left\{1 - 2e - \frac{H^*}{8ae} + 0\left(e^2, \frac{H^2}{a^2e^2}\right)\right\} \qquad (2)$$

where a is the semi-major axis of the orbit, e its eccentricity, and δ a drag parameter, discussed in the next paragraph. If $0{\cdot}02 < e < 0{\cdot}15$, as for most satellites, and if, as is almost certain, H^* does not differ from the true value of H by a factor of more than 1·5, the maximum error in equation (2) is less than 5 per cent. If e is increased to 0·2, the maximum error rises to 10 per cent. If $e < 0{\cdot}02$,

Table 1. VALUES OF $\delta = FSC/m$ FOR SATELLITES 1957α–1959λ

Satellite		Mass m (kgm.)	m/SC_D (kgm./sq. m.)	δ (sq. m./kgm).

Discoverer 8	1959λ	635	48	0·021

equation (2) is replaced by a more generalized formula[2] in terms of Bessel functions.

The parameter δ in equation (2) denotes the quantity FSC_D/m, where F is a factor which allows for rotation of the atmosphere and lies between 0·9 and 1, S is the effective cross-sectional area of the satellite perpendicular to the direction of motion, C_D is a drag coefficient the value of which normally lies between 2 and 2·3, and m is the mass of the satellite. The value of S is, as before[2], calculated on the assumption that each satellite has rotated about an axis of maximum moment of inertia, which may, however, have any direction in space, so that S is taken as the mean of the values in the two extreme forms of motion—travelling like an aeroplane propeller, and tumbling end-over-end. The value of C_D is, in accordance with the results of Cook[4] for free-molecule flow with diffuse reflexion, taken as 2·2 for the spherical and nearly cylindrical satellites, and 2·15 for the conical *Sputnik* 3. Values of δ for *Sputnik* 2 and the rockets of *Sputniks* 1 and 3, for which m and S are unknown, are found by comparison with *Sputniks* 1 and 2, as explained previously[1].

Table 1 lists the values of δ thus obtained for all the satellites launched before March 1960 and having known orbits, apart from *Explorer* 6 (1959δ) and *Lunik* 3 (1959θ), to which the theory is not applicable, since e is much greater than 0·2. The values for the *Discoverers* refer to the period after the ejection of their capsules. The error (standard deviation) in the tabulated values of δ is estimated to be rather less than 10 per cent.

Day-to-Night Variations in Density

At heights of 200–300 km. the density probably does not depart from its average value by more than 10 per cent as a result of day-to-night variation[2,3], but at heights above 400 km. this day-to-night variation becomes increasingly important. For *Vanguard* 1, which has a perigee height of about 650 km., the perigee point first entered the Earth's shadow about July 1959, and at about the same time the slope of the period-versus-time curve was greatly reduced. This effect was noted by Jacchia[5] and further examined by Martin and Priester[9,10]. Since then, five other satellites with perigee heights between 550 and 650 km. have exhibited a similar effect, as Fig. 1 strikingly demonstrates. Fig. 1 shows the change in the orbital period during the life-times of the satellites *Vanguard* 1, *Vanguard* 2 and *Explorer* 7, and their rockets (1958β2 and 1, 1959α1 and 2, and 1959ι1 and 2: perigee heights 650, 560 and 560 km., respectively). Each curve is drawn as a full line when perigee is in sunlight, and as a broken line when perigee is in the Earth's shadow. For all six satellites the slope of the period-versus-time curves shows a gradual change from a maximum value in day-time to a minimum value at night; with the three satellites for which well-defined maximum and minimum slopes are available, the values differ by a factor of about 8. This shows that the drag acting on the satellites, and hence probably the air density, is much greater by day than by night at these altitudes. For *Explorer* 1 (perigee height 350 km.) a similar but much smaller variation has been noted[8].

Results

Fig. 2 shows the values of air density obtained by applying the method of analysis already described to twenty-one of the satellites listed in Table 1. The required orbital elements are based on the Table of Artificial Satellites issued by the Royal Aircraft Establishment, Farnborough. In this table values for the *Sputniks* are from British observations and theory[7]; those for the American satellites are compiled from data issued by the U.S. prediction centres, and from theory. Values of H^* for use in equation (2) are taken from a smoothed version of the values of H previously recommended[2]. At heights below 300 km. no attempt is made to separate day-time and night-time values of density; but for satellites with perigee higher than 300 km., two values of dT/dt are distinguished, the maximum day-time value and the minimum night-time value. These have for convenience been labelled 'midday' and 'midnight' values in Fig. 2; but they represent rather the average density during the time, usually lasting several weeks, when the satellite's perigee is in the 'early afternoon' position where density appears to be highest[8] (or in the 'after midnight' position where density is least). The resulting values of density are less accurate than those at lower altitudes, with a standard deviation of perhaps ± 20 per cent above 400 km., and the curves are therefore drawn as broken lines in Fig. 2.

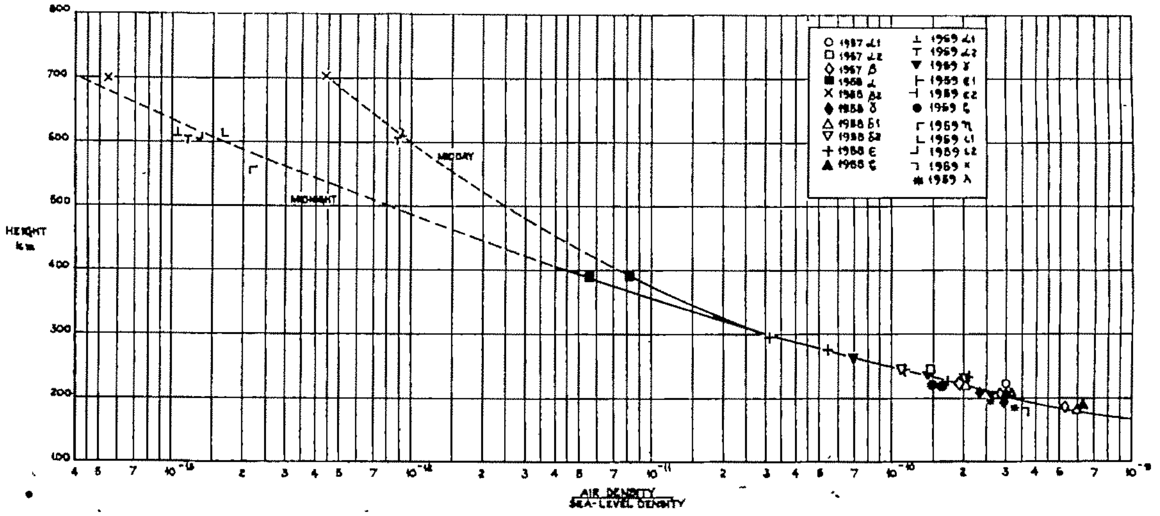

Fig. 2. Density of the upper atmosphere obtained from the orbits of 21 satellites

In discussing the features of interest in Fig. 2, it is best to begin at the lower altitudes. At heights between 180 and 300 km. there are 27 points, referring to satellites of different sizes and shapes, at different seasons, latitudes, etc.: 22 of the points differ from the curve by a factor of less than 1·35 and none by a factor of more than 1·6. This confirms previous evidence[1–3] that the density did not depart from the long-term average for 1957–59 by a factor of more than 1·5 as a result of variations with latitude or season, or from day to night, though there might be variations of larger amplitude during time intervals too short for the orbits to register, that is, less than one day.

A second significant feature of Fig. 2, not apparent at first sight, is a slow variation of density with time at heights of 180–250 km. The 24 points in this region can be divided into two groups, for October 1957–January 1959 (14 points) and for August 1959–March 1960 (10 points), respectively, and the mean curves through each of these groups give densities which are respectively about 10 per cent higher and 10 per cent lower than the curve of Fig. 2. Thus, there has apparently been a small decrease in average density between, say, mid-1958 and the end of 1959, and this explains why the points in Fig. 2 are not so near the average curve as in the corresponding graph of ref. 2. Further evidence of such a decrease in density comes from *Sputnik* 3, which was in orbit from May 1958 until April 1960: the usual methods of predicting life-time have, for this satellite, consistently under-estimated the true life-time. This unexpectedly long life would result from either a general decrease in density or a reduction in the effective cross-sectional area S of the satellite; but the latter possibility can be ruled out because, for *Sputnik* 3, S is little affected by changes in the mode of rotation[4]. The decrease in density appears to confirm the suggestion in a previous article[2] that the average air density is likely to vary in the course of the 11-year sunspot cycle. For it is well known[5–12] that solar disturbances largely control the day-to-day variations in air density at heights of 200–300 km., with the density tending to be high when sunspots are most numerous[13]. It is therefore to be expected that, as indicated by Fig. 2, the average air density will be highest at the sunspot maximum, in 1957–58, and will decrease slowly for a few years thereafter.

For heights between 300 and 700 km. the results in Fig. 2 from the various satellites agree well, and the midday and midnight values are clearly distinguished. The good agreement may be partly fortuitous, since for some of these satellites dT/dt is not well defined, being based on very small changes in period. The density given by the 'midday' curve in Fig. 2 exceeds that on the 'midnight' curve by factors of 1·6, 3, 6 and 11 at heights of 400, 500, 600 and 700 km., respectively. It should be remembered that the density changes gradually between its daytime maximum and night-time minimum, as Fig. 1 shows: the density seems to depend primarily on the zenith distance of the Sun, density being highest when the Sun is nearly overhead[6]. Thus, at heights above 500 km., the density should appear to vary with latitude and season; for example, density would be high by day in the equatorial regions and low near the poles in winter. But it would be misleading to call such effects 'variation with latitude', since such a nomenclature would tacitly attribute to terrestrial geometry an effect whose true source is solar.

At heights of 400–700 km. the major uncertainty in the values of density is, as has been emphasized before[1,2], the role of electrical drag. As a satellite moves through the ionosphere it tends to collect electrical charge, most probably negative charge. The potential to which the satellite becomes raised is not usually known, however, and, even if it were, the magnetohydrodynamic theory of the drag of a charged body in these conditions has not been properly formulated. The potential was estimated by Jastrow and Pearse[14] to be about -10 volts in darkness, while measurements on *Sputnik* 3 indicated potentials between -2 and -6 volts in sunlight[15]. If the potential is of order -10 volts, the theory of Kraus[16] suggests that at heights of 600–700 km. the electrical drag would be less than 10 per cent of the total drag, and would thus scarcely be significant in considering a change of drag by a factor of 8. At present, therefore, it appears most probable that the changes in density indicated in Fig. 2 are real; but, if the potential were much higher than assumed above, the electrical drag might have an important effect.

Another possible source of error is the effect of the radiation pressure P of sunlight. An approximate

Table 2. VALUES OF AIR DENSITY AND H GIVEN BY THE CURVES OF FIG. 2

Height (km.)	Air density / Sea-level density		Density (gm./c.c.)		H (km.)	
180	$5\cdot7\times10^{-10}$		$7\cdot0\times10^{-13}$		30	
190	$4\cdot2\times10^{-10}$		$5\cdot1\times10^{-13}$		36

250	$9\cdot8\times10^{-11}$		$1\cdot2\times10^{-13}$		40	
260	$7\cdot7\times10^{-11}$		$9\cdot4\times10^{-14}$		41	
270	$5\cdot9\times10^{-11}$		$7\cdot2\times10^{-14}$		42	
280	$4\cdot7\times10^{-11}$		$5\cdot7\times10^{-14}$		44	
290	$3\cdot8\times10^{-11}$		$4\cdot6\times10^{-14}$		47	
300	$3\cdot0\times10^{-11}$		$3\cdot7\times10^{-14}$		50	
	day	night	day	night	day	night
300	$3\cdot0\times10^{-11}$	$3\cdot0\times10^{-11}$	$3\cdot7\times10^{-14}$	$3\cdot7\times10^{-14}$	50	50
350	$1\cdot4\times10^{-11}$	$1\cdot1\times10^{-11}$	$1\cdot7\times10^{-14}$	$1\cdot4\times10^{-14}$	74	53
400	$7\cdot4\times10^{-12}$	$4\cdot5\times10^{-12}$	$9\cdot1\times10^{-15}$	$5\cdot5\times10^{-15}$	83	56
450	$4\cdot2\times10^{-12}$	$1\cdot9\times10^{-12}$	$5\cdot1\times10^{-15}$	$2\cdot3\times10^{-15}$	90	59
500	$2\cdot5\times10^{-12}$	$8\cdot2\times10^{-13}$	$3\cdot1\times10^{-15}$	$1\cdot0\times10^{-15}$	99	62
550	$1\cdot5\times10^{-12}$	$3\cdot6\times10^{-13}$	$1\cdot9\times10^{-15}$	$4\cdot4\times10^{-16}$	109	65
600	$1\cdot0\times10^{-12}$	$1\cdot6\times10^{-13}$	$1\cdot2\times10^{-15}$	$2\cdot0\times10^{-16}$	118	69
650	$6\cdot6\times10^{-13}$	$8\cdot2\times10^{-14}$	$8\cdot1\times10^{-16}$	$1\cdot0\times10^{-16}$	126	73
700	$4\cdot5\times10^{-13}$	$4\cdot2\times10^{-14}$	$5\cdot5\times10^{-16}$	$5\cdot1\times10^{-17}$	133	77

Sea-level density taken as 0·001226 gm./c.c.

analysis suggests that the change per revolution in the orbital period T of a satellite of reflectivity ε is of the order:

$$\frac{3SPT}{mg}(1+\varepsilon)\left(\frac{a}{r_2}-\frac{a}{r_1}\right)$$

where r_1 and r_2 are the distances of the satellite from the Earth's centre when it (1) enters and (2) emerges from the Earth's shadow, and g is the average gravitational acceleration while the satellite is in eclipse. In the long run, this effect will tend to cancel out, since the mean value of the second bracket is zero, though for a satellite with perigee remaining in sunlight for a long time—such as *Vanguard* 1—the effect builds up; even for this satellite, however, the change in the orbital period in six months would be only about 0·001 min., which, as Fig. 1 shows, is less than 10 per cent of the total change, even when the perigee is in darkness. The effect is likely to be important only for an inflated-balloon satellite with a perigee which is arranged to remain in darkness for several years.

To sum up, it appears likely that at heights between 200 and 300 km. the curve of Fig. 2 gives the average density for 1957–60 with a standard deviation of about 10 per cent, though the density has decreased by perhaps 20 per cent between 1958 and 1960. At heights above 400 km. the curves become less accurate, and it should be noted that, by chance, the midday values all refer to early 1959 and the midnight values to late 1959 or early 1960, so that any general decrease in density during this time, to match the decrease at lower altitudes, will have widened the apparent difference between day and night.

The curves of Fig. 2 agree well with the direct measurements of air density made by the manometers in *Sputnik* 3, as reported by Michnevich *et al.*[17]. At heights between 225 and 300 km. the difference is less than 20 per cent; at heights of 300–500 km. the direct measurements fall between the two curves of Fig. 2, within the region which would be expected from the local time of the measurements. Also the density at a height of 430 km., obtained from the expansion of a sodium cloud from a Russian Geophysical Rocket in September 1958 (ref. 18), is within 5 per cent of the midday curve in Fig. 2.

Values from the curves of Fig. 2 are listed in Table 2.

Scale Height and Air Temperature

The values of the coefficient H of equation (1), which is nearly equal to the atmospheric scale height[1], can be found from the slope of the density-versus-height curves of Fig. 2, and values are listed in the last column of Table 2. There is a slight indentation in the curve of Fig. 2 at a height near 210 km., though this is less pronounced than in the corresponding curve in ref. 2, because the scatter of the points is greater. The values of H in Table 2 are subject to maximum errors of about ± 20 per cent between 180 and 300 km. height and to larger errors at greater heights.

The value of air temperature can be deduced[1] from H and the mean molecular weight of the air, M, which is, however, not known exactly. Taking $M = 22$ at 200 km., decreasing to $M = 16$ at 500 km., and constant thereafter, and using the values of H from Table 2, the temperature obtained at a height of 200 km. is about 1,200° K.; at a height of 600 km. the value would be about 1,200° K. in darkness, or about 2,200° K. in sunlight.

Conclusions

The wide variation of density between midnight and midday at heights above 500 km., which had previously been noted for one satellite[5], has now shown itself for five other satellites (see Fig. 1), and the day-time and night-time values revealed by each conform to a consistent pattern (see Fig. 2).

At heights between 180 and 250 km., the average air density seems to have decreased appreciably, by perhaps 20 per cent, between 1958 and 1960. Since it is known that day-to-day variations in air density depend on solar activity, this change is interpreted as the beginning of an 11-year cycle, maximum density occurring at the sunspot maximum in 1957–58. At heights above 250 km. this effect ought to be more prominent.

We are grateful to the United States prediction centres, Project Space Track and the Smithsonian Astrophysical Observatory for supplying many of the values of orbital period used in this article.

OBITUARIES

Prof. J. H. C. Whitehead, F.R.S.

Prof. J. H. C. Whitehead, who died suddenly in Princeton on May 8, was one of our greatest mathematicians. His contributions to topology were both massive and fundamental. He also had an international reputation as a geometer and as an algebraist. In research he went from strength to strength, uniting profound study with ever-growing creativity.

Henry Whitehead, as he was known, was Waynflete professor of pure mathematics in Oxford. He lived in the Otmoor village of Noke where his wife Barbara runs a farm, in which he took the liveliest interest. Their exuberant hospitality brought many and varied friends to Manor Farm, as it had done previously to their house in north Oxford. They shared great zest for life and enjoyed a marriage of surpassing happiness. They have two sons, David and Oliver.

Whitehead was born in India in 1905. His father, Bishop of Madras and brother of the philosopher A. N. Whitehead, sent him to Eton, a school for which he always had the highest regard. He went on to read mathematics at Balliol under H. W. Nicholson. After graduating, he first tried financial work in London but soon decided on a university career.

In 1928 he went to Princeton for three years as a Commonwealth Fellow to study under Oswald Veblen, whose high standards deeply influenced his mathematical thought and style. Together they wrote the important Cambridge Tract, "The Foundations of Differential Geometry", which is now regarded as a classic, and Whitehead also wrote a number of papers on differential geometry, including his Princeton Ph.D. thesis. Although he never lost his interest in geometry, it quickly became dominated by the study of topology, to which he was initiated by Veblen, Alexander and others. This young subject had run into formidable problems which have only recently begun to give way. The attempt to solve these strongly developed Whitehead's conceptual powers and led him towards some of his finest work.

On his return to Oxford as Tutorial Fellow at Balliol, he plunged into college life with huge enjoyment. He was an inspiring and open-hearted teacher, to whom mathematics mattered and the clock did not. He was an entertaining and resourceful talker with a highly independent view of people and affairs. He loved the more sociable kinds of sport, perhaps cricket most of all. In the Alps he did some fine climbs with Alexander, such as the Zmutt ridge of the Matterhorn and the Grand Charmoz, and he was also a good skier.

Following his marriage in 1934 Whitehead began to publish those pioneer studies which have made him famous. These were mostly on topological subjects, but there are also papers dealing with Lie algebras and free groups. By the beginning of the Second World War he was already concentrating on homotopy theory more than classical topology, and this remained his main interest until two years ago. The fifty papers he wrote on this subject have had great influence on its development and contain some of its most important theorems and ideas.

During the War, Whitehead worked for the Admiralty and the Foreign Office, but his research still continued. He was elected to the Royal Society and then, at the end of the War, he was chosen to succeed Dixon as Waynflete professor at Oxford. This made him a Fellow of Magdalen, where he continued to enjoy many aspects of college life. He never lacked students to inspire with his great knowledge and love of mathematics. Always generous with time and ideas, he managed to be encouraging while at the same time maintaining the highest standards. Students came to him from all over the world. To him is largely due the quality of the work which many of them have since done.

At Oxford Whitehead did much to foster the new Mathematical Institute, with its friendly atmosphere and spirit of hard work. He helped to found the very successful series of British Mathematical Colloquia. Through this and through the London Mathematical Society the invigorating effect of his personality was felt far outside Oxford. He valued international contacts and kept in close touch throughout with topologists in the United States, France, Poland, the U.S.S.R. and elsewhere.

Last year he felt ready to return, with vastly increased powers, to those problems which had challenged him as a student. Accordingly, he went on sabbatical leave to the United States, and it was there in Princeton that he died. I. M. James

Dr. C. S. Gum

On April 28, Dr. Colin Stanley Gum, one of Australia's outstanding younger generation astronomers, was killed in a skiing accident at Zermatt, Switzerland. He had just been appointed to the post of senior lecturer in astrophysics in the University of Sydney, and his visit to Europe was in connexion with plans for the installation of a reflecting telescope by the University.

Colin Gum was born in 1924. He graduated with honours in physics at the University of Adelaide in 1949 and proceeded to Mount Stromlo Observatory, where, in 1955, he obtained his Ph.D. degree in astronomy, the first given by the Australian National University. After a short period on the staff of the University of Adelaide, he joined the Commonwealth Scientific and Industrial Research Organization Radiophysics Laboratory in 1956, and in 1959 he was awarded a Carnegie fellowship to the Mount Wilson and Palomar Observatories, where he was working immediately prior to the fatal trip to Europe.

His work alternated between radio and optical astronomy but was consistently concerned with interstellar matter. His main contribution in the optical field was a major survey of hydrogen emission regions in the southern sky. In the Radiophysics Laboratory he studied the distribution in the Galaxy of interstellar hydrogen, using 21-cm. radio observations. Through this work he became a key member of the International Astronomical Union Commission which set up a new system of galactic co-ordinates in 1958, primarily on the basis of such information. At Mount Wilson and Palomar he had begun to work on interstellar polarization in external galaxies.

His death is deeply regretted by his colleagues in Australia, both radio and optical, and is a very serious loss to Australian science.

J. L. Pawsey

NEWS and VIEWS

Queen's Birthday Honours List

The following names of scientists and others associated with scientific work appear in the Queen's Birthday honours list:

K.C.B.: Frank C. Francis, director and principal librarian, British Museum.

K.B.E.: Dr. Robert Cockburn, chief scientist, Ministry of Aviation.

Knights: Dr. Robert S. Aitken, vice-chancellor of the University of Birmingham; Dr. Basil F. J. Schonland, director, Research Group, U.K. Atomic Energy Authority; Dr. Gordon B. B. M. Sutherland, director of the National Physical Laboratory; Dr. Henry G. Thornton, foreign secretary of the Royal Society; Prof. Robert D. Watt, emeritus professor of agriculture in the University of Sydney.

C.B.: Dr. F. M. Lea, director of the Building Research Station, Department of Scientific and Industrial Research; Dr. J. S. McPetrie, director-general of Electronics Research and Development, Ministry of Aviation.

C.M.G.: N. F. Mitchell, president of the Royal Agricultural Society of Victoria; J. H. Parry, principal of University College, Ibadan, Western Region, Nigeria.

C.B.E.: Dr. T. E. Allibone, director of the Research Laboratory, Associated Electrical Industries, Ltd.; Prof. N. S. Bayliss, professor of chemistry in the University of Western Australia; L. Farrer-Brown, director of the Nuffield Foundation; J. S. Carter, chief alkali inspector, Ministry of Housing and Local Government; A. P. S. Forbes, director of agriculture, Tanganyika; Capt. G. I. D. Hutcheson, for services to the engineering profession in Australia; Prof. T. G. H. Jones, professor of chemistry in the University of Queensland; W. J. Langford, headmaster of Battersea Grammar School; R. B. McConnell, director of geological surveys, British Guiana; K. D. S. MacOwan, director of veterinary services, Kenya; Prof. M. E. L. Mallowan, professor of Western Asiatic archæology, University of London, and director of the British School of Archæology; H. F. Mooney, forestry and soil conservation adviser, Middle East Development Division, Lebanon; Prof. A. W. Scott, professor of chemical engineering, Royal College of Science and Technology, Glasgow, for contributions to the food dehydration industry and services to the Aberdeen research establishment of the Ministry of Agriculture, Fisheries and Food; A. F. M. Smith, director of lands and surveys, Uganda; Dr. R. A. Smith, chief scientific officer, Royal Radar Establishment, Ministry of Aviation; J. C. C. Stewart, deputy managing director, Production Group, U.S. Atomic Energy Authority; Dr. F. R. Tubbs, director of the East Malling Research Station, Maidstone; Dr. E. I. White, keeper of palæontology, British Museum (Natural History).

I.S.O.: P. A. Allison, lately conservator of forests, Western Region, Nigeria; T. Lacey, principal in the Department of Scientific and Industrial Research; E. W. Pratt, senior principal scientific officer, Admiralty.

Atomic Energy Research Establishment Appointments:

Mr. B. S. Smith

Mr. B. S. Smith has been appointed head of the Isotope Research Division of the Atomic Energy Research Establishment. This Division was formed from the Isotopes Division as part of the re-organization of isotope production and application work carried out by the Atomic Energy Authority last year. The Division has recently completed a move from Harwell to the Wantage Research Laboratory, six miles away, which was opened by the Minister for Science, Lord Hailsham, on May 16. Mr. Smith is a graduate of King's College, London, where he was a demonstrator in physics from 1934 until 1939. During the War he worked at the Radar Research and Development Establishment, first on gun-laying radars and later on 'Identification, Friend or Foe Systems'. In 1944 he transferred to the Tube Alloy Project, and went to Canada, where he worked on the instrumentation for the Canadian *NRX* reactor. He returned to Harwell in 1947, and shortly afterwards joined the newly formed Health Physics Division. He became deputy head of the Division in 1954, and head when Dr. W. G. Marley took over the Radiological Protection Division of the Authority's Health and Safety Branch.

Mr. N. G. Stewart

Mr. Smith's place as head of the Health Physics Division will be taken by Mr. N. G. Stewart, who is at present head of the Health and Safety Division at the Dounreay Experimental Reactor Establishment. Mr. Stewart graduated at the University of Aberdeen in 1937, where he gained first-class honours in mathematics and natural philosophy. After a period teaching, he joined the Radar Research and Development Establishment at the beginning of the War, and became leader of the Aerial and Waveguide Systems Section. He joined the Health Physics Division at Harwell in 1948, and became head of the Radiation Measurements Group. He was transferred to Dounreay in 1958.

Chemical Engineering at Nottingham:

Prof. R. Edgeworth Johnstone

Dr. Robert Edgeworth Johnstone, at present assistant technical manager of Springfield Works, United Kingdom Atomic Energy Authority, has been appointed to be the first Lady Trent professor of chemical engineering in the University of Nottingham. The chair has been endowed by Boots Pure Drug Co., Ltd., Nottingham, in recognition of the services rendered to the University by the late Lord Trent and Lady Trent. Dr. Edgeworth Johnstone was educated at Wellington College and the Royal Military Academy, Woolwich, after which he spent two years at the Manchester College of Technology and a further year at University College, London. He graduated with first-class honours in applied chemistry and was awarded the degree of M.Sc. in chemical engineering of the University of London. In 1958, he was awarded the degree of doctor of science. He has had wide experience in Great Britain and abroad of large-scale plant management and development, and after the War was design engineer for important new petrochemical and chemical units in Lancashire and London. For almost ten years he has been with the Ministry of Supply with special responsibility for pilot plant experiments and process studies, and he has published numerous articles on the problems of translating experimental and small-scale production methods into full-scale commercial schemes.

Research in Optical Design at the Imperial College, London

An optical design group is to be set up at the Imperial College of Science and Technology, London, under the direction of Dr. C. G. Wynne, of the Wray Optical Co., Ltd., with the support of a grant for an initial period of seven years of £9,400 a year from the Department of Scientific and Industrial Research. The group, initially employing a staff of four in addition to Dr. Wynne, will be established under Prof. W. D. Wright, professor of technical optics in the College. The scientific programme will be: (1) to develop new methods of lens design, including the use of electronic digital computers, and to give instruction in these methods; (2) to design and construct lens systems of orthodox type but improved performance; of novel types including systems employing aspheric surfaces; and of specialized systems required in very limited numbers but having unusual performance characteristics, such as for space research.

Dr. C. G. Wynne

Dr. Wynne graduated at Exeter College, Oxford, to which he won an open science scholarship in 1930. He joined Messrs. Taylor, Taylor and Hobson, Ltd., where he worked on lens design. In 1943 he became chief lens designer to Messrs. Wray (Optical Works), Ltd., and in 1949 a director of Wray (Developments), Ltd., a subsidiary company which has undertaken a considerable volume of new optical design. In 1955 he became technical director of Wray (Optical Works), Ltd. In 1953 he was awarded a Ph.D. by the University of London. Dr. Wynne is the honorary business secretary of the Physical Society and is the honorary secretary of the newly established Institute of Physics and the Physical Society. He has acted as English language editor of *Optica Acta* since its inception in 1954.

Forest Products Research Laboratory: Mr. A. C. Copisarow

Mr. H. Wooldridge, deputy director, Stations Division, in the Department of Scientific and Industrial Research, has agreed to withdraw his acceptance of the directorship of Forest Products Research (see *Nature*, January 23, p. 212) at the special request of the secretary of the Department, because of the increasing pressure of work at headquarters of the Department. Mr. A. C. Copisarow, at present scientific attaché at Paris, has been appointed director of the Forest Products Research Laboratory in succession to Dr. F. Y. Henderson, who retires in October. Mr. Copisarow graduated in 1942 in the honours school of geology at the University of Manchester. He served in the Royal Navy, for four years on radar duties, and during 1946–54 was with the Joint Intelligence Bureau of the Ministry of Defence. He has published papers on the colloidal chemistry of silica. A former Council of Europe Research Fellow, he has served at the British Embassy in Paris for six years.

The United States Geological Survey: Dr. W. H. Bradley

In appreciation of the work of Dr. 'Bill' Bradley, chief geologist of the United States Geological Survey during 1944–59, the *Americal Journal of Science* has published a 'Festschrift' of 38 papers (*Amer. J. Sci.*, Bradley Volume, 258–A. Pp. 433 + 10 pl.; 1960) ranging over many topics in the Earth sciences. Dr. Bradley joined the U.S. Geological Survey as a 'geologic aid' in 1921, and soon became well known for his distinguished work on the oil shales and other strata of the lacustrine Green River Formation of middle Eocene age. These studies were interrupted by the War, when he was appointed chief of the Military Geology Unit responsible for supplying geological information to the American forces; and immediately afterwards he took over the leadership of the Geologic Division of the U.S. Geological Survey, which expanded under his charge from 400 geologists in 1944 to close on 1,000 in 1955. Recently he relinquished these administrative responsibilities to return to his initial research work. The volume in his honour is a fitting tribute to many years of good management of the largest geological organization in the Western world.

Advisory Committee on Poisonous Substances used in Agriculture and Food Storage

Sir Charles Dodds, Courtauld professor of biochemistry in the University of London, and director of the Courtauld Institute of Biochemistry at the Middlesex Hospital, has been appointed chairman of the inter-departmental Advisory Committee on Poisonous Substances used in Agriculture and Food Storage, in succession to Sir Solly Zuckerman. This Committee was recently reconstituted to include the following five members from outside the Government service; Prof. J. H. Gaddum, director of the Institute of Animal Physiology, Cambridge; Prof. Andrew Wilson, professor of pharmacology, University of Liverpool; Dr. J. Hamence, public analyst and agricultural analyst; Mr. F. H. Garner, principal of the Royal Agricultural College, Cirencester; and Prof. A. R. Clapham, professor of botany, University of Sheffield. The Committee was appointed in March 1954 to keep under review all risks that may arise from the use of toxic substances on agricultural products and in the storage of food, and to make recommendations to the Ministers concerned.

National Reference Library of Science and Invention

Answering a question regarding progress with the proposed National Reference Library of Science and Invention in the House of Lords on May 31, the Minister for Science said it is proposed to house this Library in a new Patent Office building to be erected on the South Bank, London. The terms of a lease of the site are now being settled between the Ministry of Works and the London County Council, and it is hoped to start building in the spring of 1963 with the view of completion by the end of 1965. Lord Hailsham had stated on July 30, 1958, that the Library would be built up and expanded from the existing Patent Office Library. He now said that it has been decided that it would be in the long-term interest of learning and of the completeness of the national collections of scientific literature for the National

Reference Library of Science and Invention to be formed as part of the British Museum Library, although housed as a separate unit. Scientific publications at present in the British Museum Library would be incorporated in the new Library. Care would be taken to safeguard the interest and convenience of those who use the present Patent Office Library, and they would be represented on an Advisory Committee to be set up when the new Library is brought into operation. Viscount de L'Isle welcomed this decision on behalf of the Trustees of the British Museum, and said that it would in due course make available to students and research workers the existing scientific resources of both the Patent Office and of the British Museum scientific collections in a compendious way and with the minimum of duplication.

State Scholarships and Commonwealth Co-operation

In the House of Lords on June 1, Lord Tweedsmuir asked the Government whether it would consider permitting up to 100 of the 2,000 State scholarships annually awarded in Britain to be tenable at Canadian or other Commonwealth universities if the recipient so elected. Lord Hailsham, replying for the Government, said that the Government would consider the matter in the light of the recommendations of the Anderson Committee. Asked by Lord Dalton to accelerate consideration of this question in view of the opportunities which Canadian and Australian universities can offer, Lord Hailsham agreed that it is a separate question from most of the contents of the Anderson Report, but thought that consultation with the Commonwealth Governments would be necessary before he could reply. Lord Casey suggested that the success of the proposal would depend on reciprocity between Commonwealth countries and the United Kingdom, and that into this consideration of cost and of available places would enter.

Preservation of North Devon Countryside

An area of the North Devon countryside about 66 square miles in extent is to be protected by the confirmation by the Minister of Housing and Local Government of an order made by the National Parks Commission. The area includes the whole of the Hartland Peninsula and such places as Clovelly, Braunton Burrows, Croyde, Woolacombe and Combe Martin, near the western edge of the Exmoor National Park. The order, which is made by the National Parks Commission under the National Parks and Access to the Countryside Act, 1949, designates these parts of North Devon as "Areas of Outstanding Natural Beauty", not as a National Park. The responsibility for preserving and enhancing the natural beauty of the landscape rests with the local planning authority, Devon County Council. Government grants can be made at the rate of 75 per cent towards the cost of treating derelict land, tree planting and preservation, and removing disfigurements.

Nature Conservation in Africa

Answering questions about Nature conservation in the Colonial territories in the House of Commons on June 2, the Secretary of State for the Colonies, Mr. Iain Macleod, welcomed the opportunity to reaffirm the Government's concern for wild life in Africa. Wild life conservation measures are, he said, continuously under review in the East and Central African territories, and in the past decade much has been done to establish and consolidate national parks and reserves. More use could be made of technical knowledge in developing the wild-life reserves, and the voluntary co-operation of the African populations is essential. The International Union for the Conservation of Nature, in consultation with other international agencies, is exploring the possibility of convening next year in Africa a conference on conservation. Mr. Macleod said that in a few weeks he would be able to study a detailed report by Dr. E. B. Worthington on his recent visit to Africa and the need for further help.

Journal of Child Psychology and Psychiatry

A new journal which will be generally welcomed has been issued by the Association of Child Psychology and Psychiatry. It is the *Journal of Child Psychology and Psychiatry and Allied Disciplines*, and is published under a distinguished editorial board of international authorities. The joint editors consist of a research psychologist, psychiatric social worker and a well-known physician in child-psychiatry, Dr. Emanuel Miller, while the corresponding editors are Prof. Milton Senn, Department of Pediatrics, Yale University, and P. H. Mursen, Department of Psychology, University of California. The *Journal* is attractively produced and the first issue (Vol. 1, No. 1 (January 1960). Pp. 98. Published quarterly. Subscription rates: To members of the Association of Child Psychology and Psychiatry 63*s*. per annum, inclusive of membership. To private individuals 105*s*. (15 dollars) per annum. To libraries and institutions 140*s*. (20 dollars) per volume. London and New York: Pergamon Press, 1960) contains articles which are refreshingly free from the jargon so beloved by students of human behaviour. The standard is set in the first article by Dr. Miller, who traces the origins of child-psychiatry, while Prof. Leo. Karner (Johns Hopkins University) shows that behaviour symptoms do not always indicate psychopathology; the clarity and brevity of his writing has much to commend itself to his fellow-American psychiatrists. Other articles deal with the effects of early deprivation and separation on children, manic-depressive psychosis in childhood, a gap in the structure of general psychology and a description of the training provided in child-psychotherapy at the Tavistock Clinic. Provided that the new journal can maintain this standard and keep itself free from psychiatric expertize, it could prove as useful to teachers and intelligent parents as to the professional child-psychiatrist and psychologist for whom it is intended.

Pavlov Journal of Higher Nervous Activity

This journal has been added to the list of Russian journals which are being published in English translation. By arrangement with the Soviet authorities, 'rush' copies of the original journal and its illustrations are to be made available, so that the delay in publication of the translation can be made as short as possible. The first issue of the 1959 volume contains 18 original communications, together with a short review of work carried out in the United States of America during the years 1954–57 on conditioned reflexes in animals. There is an obituary of the eminent Russian physiologist, L. A. Orbeli (Vol. 9, No. 1. Translated from the Russian. Pp. 140. Published bi-monthly. Approximately 1,000 pages per volume. Annual subscription 210*s*.; 30 dollars. London and New York: Pergamon Press, 1960).

Medical and Biological Compilation

THE second edition of "Current Indexing and Abstracting Periodicals in the Medical and Biological Sciences" attempts to provide an annotated list of all the most important indexing and abstracting periodicals in medicine and the allied sciences published currently throughout the world, and the number of titles has been increased from 142 in the first (1953) edition to 310 (World Health Organization. Library News, Vol. 12, Supplement 2. Pp. 85. Geneva: World Health Organization, 1959). In general annual publications containing review articles are excluded, but the yearbook series, containing the abstracts, are included. Periodicals are listed alphabetically by title, with the name and address of the publisher and/or responsible organization, first year of publication, current subscription price, year and volume number of the first volume in the World Health Organization holding, frequency of publication, number of periodicals regularly scrutinized and of abstracts or title entries published annually.

Transvaal Museum

THIS active museum publishes both a *Bulletin* and *Annals*. The former for January 1960, No. 4, includes some notes on mammal specimens as museum material and the collecting expedition of Colonel Jack Scott to Somalia. A short article also describes the bird-life at Sandwich Harbour. The April issue of the *Annals* (14, Part 1; 1960) contains an important key to the genera of South African freshwater and estuarine gastropods, observations on the locomotion of the South African adder, *Bitis peringueyi*, and on the early post-natal development of multi-mammate mice. The dibatag, *Ammodorcas clarkei*, is also dealt with in an important illustrated paper by Mr. J. Meester.

Psychiatric Services and Architecture

A BOOKLET published by the World Health Organization attempts an analysis, not only of the planning and management of psychiatric hospitals, but also of the structure and function of other psychiatric services such as out-patients' departments, psychiatric wards in general hospitals, rehabilitation facilities, and other mental health services (Public Health Papers, No. 1: Psychiatric Services and Architecture. By A. Baker, R. Llewelyn Davies and P. Sivadon. Pp. 59. Geneva: World Health Organization; London: H.M. Stationery Office, 1959. 2 Swiss francs; 3*s*. 6*d*.). It is the joint work of two psychiatrists and an architect who has specialized in hospital architecture, but it also takes account of the comments and suggestions of twenty-nine other psychiatrists and four architects from other countries. It represents an international approach to the problem of how psychiatric services can best be organized in the interests of the patients and be given suitable architectural expression. The types of buildings proposed are very different from the gloomy, prison-like mansions which until recently were regarded in many parts of the world as the only appropriate places in which to incarcerate mental patients; the approach to the patient is based upon the desire to re-integrate him into society with all possible speed, and to provide him with surroundings that will contribute to that end.

Roe Deer

Two of Britain's native deer, the red and the roe, have been known to inhabit the country since prehistoric times. The roe is now more widely distributed in England than the red, but, in Scotland, the red deer is the more widespread species. There are few, if any, in Wales, and none in Ireland. Because there are no predatory animals to keep these deer in reasonable numbers, the burden of doing this rests on the owners of the land on which they live. As the planted forests grow taller the problem of control will increase, and it is important that game-keepers and foresters should be familiar with their habits. To help them, the Forestry Commission has produced another of its attractive illustrated booklets, on the roe deer, which would be equally useful for natural history lessons in schools (Leaflet No. 45: The Roe Deer. Pp. 16. (London: H.M. Stationery Office, 1960.) 1*s*. 6*d*. net). It describes not only methods of control but also how these attractive animals may be stalked, the terms of venery, the calls of the roe, and, not least attractive, a suggested method of cooking roast haunch of roe.

A New British Transistorized Computer

THROUGH the joint enterprise of the General Electric Company and International Computers and Tabulators, Ltd., 149 Park Lane, London, W.1, a new, fully transistorized, automatic digital computer, the 1301, has been produced. This machine has characteristics which place it in the front rank of the large British computers which are available at the present time. It has storage, both on magnetic cores and on drums, the former in units of 400 words; the latter in units of 12,000 words; magnetic tape transports and a high-speed line-at-a-time printer are also available. The arithmetical speeds of the machine are such that addition and like operations take about 25 μsec., and multiplication about eight times as much. These fast operating speeds are achieved with the remarkably low pulse-operating time of 1 Mc./s.; this is apparently due to the unusual feature of the machine, namely, that it operates in serio-parallel decimal code, each decimal digit being represented by signals on four lines in parallel and each computer word consisting of twelve decimal digits. Probably the most surprising feature of the machine is its low power consumption, which the makers state to be only 4 kW. In common with most recently produced machines, a comprehensive range of sub-routines and automatic programming facilities is also available. Because it is built with magnetic tape as a standard and planned-for ancillary, this machine is more attractive than many of the British machines of the immediate past, in which the later addition of magnetic tape has only been achieved by considerable alterations.

Rock Pressure and Earthquakes

WHEREAS the virgin pressure of the fluids in rock formations at depth can be measured readily, the pressure in the solid rock itself could not, until recently, be measured directly. In practical problems concerned with mining and deep drilling it has been customary to assume that the pressure is satisfactorily defined by the weight of overburden. A method of direct measurement has been developed in Sweden which shows that this assumption is too simple. The method and results are described by Nils Hast in a recent issue of *Sveriges Geologiska Undersökning* (Ser. C, No. 560: The Measurement of Rock Pressure in Mines. By Nils Hast. Pp. 183. Stockholm: Sveriges Geologiska Undersökning, 1958).

The principle is to pre-stress a small stress-measuring cell situated in a hole drilled some distance into the rock, and then to cut away a portion of the surrounding rock by drilling an annular hole co-axial with and enclosing the first. The stress in the core of rock containing the cell is thus removed, and the difference between the original and final load measured by the cell gives the absolute value of the stress acting in the rock at the measuring point. The cell measures stress in one direction only; by using three boreholes the stress ellipsoid may be determined.

This method was first tried in 1951 in the Grängesberg iron mines, and has since been improved and applied to other mines. It has been found to be of great value in investigating the stability of roofs, walls and pillars, and the use of block caving as an efficient means of ore extraction. Besides their immediate practical value, however, the measurements promise to throw new light on the dynamics of the Earth's crust. In all cases where rock pressures have been measured in Sweden there has been found a pronounced excess of the horizontal component, usually 1·5–3·5 times the amount accounted for by the weight of overburden. These large horizontal stresses are ascribed by Hast to secular movements in the crust. Since many earthquakes are believed to be due to the sudden failure of parts of the crust following a steady accumulation of stress, it is further suggested that periodic measurements of rock pressure in earthquake regions might disclose the stage reached in the preliminary build-up, leading to the possibility of earthquake prediction.

The Wellcome Trust: Grant to the Massachusetts General Hospital, Boston

The Wellcome Trustees have made a grant of £50,000 to the Massachusetts General Hospital, Boston, for the establishment of a Henry S. Wellcome research chair in medical science. The professor will be chosen by a special committee of the Massachusetts General Hospital, Harvard University, and the Massachusetts Institute of Technology, from a number of workers who have already achieved a high scientific reputation for their researches. The appointment will be made for ten years. This is the largest single grant to be made by the Wellcome Trustees to a medical research centre in the United States. In 1956 they made a grant of nearly £25,000 to the University of Pennsylvania to provide a Wellcome associate research professorship of anesthesiology for five years, and earlier in the present year they made a grant of £15,000 to construct a laboratory for cardiovascular research within the Department of Medicine at Johns Hopkins Hospital, Baltimore.

The Waverley Gold Medal Competition

The Scientific Advisory Board of *Research* has decided to continue the Waverley Gold Medal essay competition, and this year will be the eighth year in succession in which it is offered. The Waverley Gold Medal, named after the late Lord Waverley, together with £100 will be awarded for the best essay of about 3,000 words describing a new scientific project or practical development, giving an outline of the background, the experimental results and the potential application of the project or process in industry. A second prize of £50 will be awarded, and also a special prize of £50 for the best entry from a competitor under the age of thirty on July 31. Further information can be obtained from the Editor of *Research*, 4/5 Bell Yard, London, W.C.2. The last date of entry is July 31.

Teratology Society

Following the fourth Teratology Conference, which was held at the Memorial Sloan-Kettering Cancer Center in New York City and attended by 76 scientists from Canada, England, France, Germany and the United States, the Teratology Society was formed. One of the main purposes of the Society is to hold regular meetings at which investigations concerned with etiology and morphogenesis of congenital malformation can be presented and discussed. The following officers were elected: *President*, Dr. Josef Warkany (Cincinnati); *President-elect*, Dr. James G. Wilson (Gainesville); *Secretary-Treasurer*, Dr. Marjorie M. Nelson (San Francisco); *Recorder*, Dr. Sidney Q. Cohlan (New York); *Council*, Dr. F. Clarke Fraser (Montreal), Dr. David L. Gunberg (Portland) and Dr. M. Lois Murphy (New York). The National Foundation assisted in the formation of the Society with advice and financial aid. Further information concerning the society can be obtained from Dr. Marjorie M. Nelson, Department of Anatomy, School of Medicine, University of California, San Francisco, 22.

The Agricultural Society of India

The following have been elected members of the new Executive Council for 1960 of the Agricultural Society of India: *President*, Dr. J. N. Mukherjee; *Vice-president*, Sri Bimal Chandra Sinha; *Editor*, Dr. P. K. Sen; *Secretary-treasurer*, Sri. R. M. Datta; *Other members*, Dr. N. R. Dhar, Dr. J. C. Sen Gupta, Dr. B. C. Kundu, Dr. H. K. Nandi, Dr. M. C. Das, Dr. S. K. Mukherjee, Dr. T. M. Das, Dr. U. N. Chatterjee, Dr. D. N. Roy Choudhury, Sri R. S. Roy, Sri T. K. Bose.

University News:

Birmingham

Dr. S. Mandelstam, assistant research physicist, Department of Physics, University of California, has been appointed to the newly established chair of mathematical physics within the Department of Mathematical Physics from October 1. The following lectureships are also announced: Dr. R. W. Whitworth (physics), Dr. A. B. Robbins (physics), Dr. J. R. Majer (chemistry), Dr. E. H. Creaser (senior lecturer in microbiology), Dr. F. W. J. Teale (biochemistry), and Dr. D. G. Walker (biochemistry). Research fellowships are as follows: A. M. Hoare (pure mathematics), J. S. Lilley (nuclear physics), B. Cockayne (William Gibbins Research Fellow in the Department of Physical Metallurgy) and E. N. Corlett, senior Research Fellow in the Department of Engineering Production).

Bristol

Appointments to lectureships are as follows: Dr. P. G. Drazin (mathematics), Dr. A. E. Scott (chemistry), Mr. J. K. Whitaker (mathematical economics). Mr. K. F. H. Murrell has been appointed a Research Fellow in the Department of Psychology. Dr. D. H. Perkins has been elected reader in physics.

Durham

The following appointments to lectureships are announced: Dr. O. E. W. R. Kurth (senior lecturer in mathematics), Mr. D. J. Bellamy (botany), Dr. R. D. Chambers (chemistry), Dr. D. P. Hendry (psychology), Dr. D. M. Hirst (geochemistry), Dr. M. J. Morant (applied physics).

London

DR. W. KLYNE, reader in biochemistry at the Postgraduate Medical School of London, has been appointed to the University chair of chemistry tenable at Westfield College; and Dr. R. E. O. Williams, deputy director of the Central Public Health Laboratory, Colindale, has been appointed to the University chair of bacteriology tenable at St. Mary's Hospital Medical School. Appointments to readerships are as follows: Dr. J. H. Green (physiology), tenable at Middlesex Hospital Medical School; Dr. H. J. J. Blackwood (oral anatomy) at the Royal Dental Hospital of London School of Dental Surgery; J. C. de C. Henderson (reinforced concrete structures), tenable at the Imperial College of Science and Technology; A. J. Buller (physiology), tenable at King's College).

The Night Sky in July

FULL moon occurs on July 8d. 19h. 37m. U.T., and new moon on July 23d. 18h. 31m. The following conjunctions with the Moon take place: July 7d. 12h., Jupiter 5° S.; July 8d. 18h., Saturn 4° S.; July 17d. 17h., Mars 3° N.; July 19d. 10h., Aldebaran 0·4° S. Mercury and Venus are too close to the Sun for observation. Mars rises at 0h. 30m., 0h. 00m. and 23h. 25m. at the beginning, middle and end of the month, respectively; its stellar magnitude is $+0·9$ and its distance from the Earth on July 15 is 137 million miles. Mars is now prominent in the eastern sky before sunrise. Jupiter sets at 3h. 05m., 2h. 05m. and 0h. 55m. on July 1, 15 and 31, respectively. It is near the boundary between Sagittarius and Ophiuchus, its stellar magnitude is $-2·1$ and its distance from the Earth in the middle of the month is 400 million miles. Saturn is also in Sagittarius, setting shortly after sunrise at the beginning of the month, and at 3h. 30m. and 2h. 20m. on July 15 and 31, respectively. Its stellar magnitude is $+0·3$, and it is in opposition on July 7, when its distance from the Earth is 840 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: July 3d. 21h. 44·0m., κ Vir. (*D*); July 19d. 10h. 20·3m., Aldebaran (*D*); July 19d. 11h. 34·1m., Aldebaran (*R*). *D* and *R* denote disappearance and reappearance, respectively. The Earth is at aphelion on July 2, its distance from the Sun being 94·6 million miles.

Announcements

THE Council of the National Institute of Industrial Psychology has awarded the Vernon Prize for 1960 to Dr. R. B. Buzzard of the Industrial Psychology Research Group of the Medical Research Council. Dr. Buzzard has been engaged for ten years in research into attendance and absence from work, and has made an exceptional contribution to knowledge in this difficult field.

THE Department of Mathematics and Natural Science of the Bavarian Academy of Science, Munich, in celebration of its two hundredth Jubilee, is offering a prize of 8,000 D.M. for the best essay on "Die Rückkoppelung als Urprinzip der Lebensvorgänge". The competition is open to persons with a doctorate or other recognized qualifications. The essay is to be written in the German language and presented by August 1, 1961. Further information can be obtained from Prof. R. Sauer, Bayerische Akademie der Wissenschaften, Munchen 22, Marstall-Platz 8.

THE eleventh International Congress of Entomology is to be held in Vienna during August 17–25. Further information can be obtained from Dr. Max Beier, General Secretary, P.A. Natural History Museum, Vienna 1, Burgring 7.

THE annual conference of the Institute of Sewage Purification will be held at Scarborough, during June 21–24. Further information can be obtained from the Secretary of the Institute at Maple Lodge, Maple Cross, Rickmansworth, Herts.

THE Photoelectric Spectrometry Group is organizing a meeting on "Spectrofluorimetry" at the Inorganic Chemistry Department, South Parks Road, Oxford, on July 8. Further information can be obtained from K. A. Macdonald, Unicam Instruments, Ltd., Arbury Works, Cambridge.

THE Danish Atomic Energy Commission is organizing an international summer course on "Plasma Physics" at its Research Establishment, Riso, during August 1–12. Further information can be obtained from the Danish Atomic Energy Commission, Research Establishment, Riso, Roskilde.

THE tenth General Assembly and nineteenth International Congress of the International Geographical Union are to be held in Stockholm during August 6–13. Further information can be obtained from the Assistant Secretary of the Geographical Association, Park Branch Library, Duke Street, Sheffield 2.

A JOINT meeting of the Challenger Society and representatives from the Marine Laboratories (Development Commissioners' Scheme) has been convened at the Zoological Laboratory, Downing Street, Cambridge, during June 23–24. Further information can be obtained from Dr. R. Bainbridge, Zoological Laboratory, Downing Street, Cambridge.

THE third Australasian Conference on "Radiation Biology" is to be held at the University of Sydney during August 15–18. Further information can be obtained from Dr. Peter Ilbery, Department of Preventive Medicine, University of Sydney, N.S.W.

THE eighth International Symposium on "Combustion" is to be held at the California Institute of Technology, Pasadena, during August 29–September 2. Further information can be obtained from the Office of Industrial Associates, California Institute of Technology, Pasadena, California.

THE twenty-first International Geological Congress will be held in Copenhagen at the Mineralogical-Geological Museum of the University during August 15–25. The Congress is being organized jointly by Denmark, Finland, Iceland, Norway and Sweden. Further information can be obtained from the General Secretary, International Geological Congress, Mineralogisk Museum, Øster Voldgade, Copenhagen K.

THE tenth annual meeting of holders of Nobel Prizes will be held in Lindau during July 4–8. Among those present who are to speak are Prof. H. A. Krebs (Oxford), Prof. F. Sanger (Cambridge), Prof. G. Domack (Wuppertal-Elberfeld), Prof. C. Heymans (Ghent), Prof. W. P. Murphy (Brookline), Prof. A. Butenandt (Munich), Prof. R. Kuhn (Heidelberg), Prof. A. I. Virtanen (Helsinki), Prof. H. Dam (Copenhagen), Prof. W. R. Hess (Zurich), Prof. Hans von Euler-Chelpin (Stockholm), Prof. G. von Hevesy (Stockholm) and Dr. P. H. Müller (Basle). Further information can be obtained from the Sekretariat der Tagungen der Nobelpreistrager, Lindau (B), Postfach 11.

MINOR ELEMENTS IN NUTRITION

THE 132nd meeting of the Nutrition Society (58th of the Scottish Group) was held in the Hannah Dairy Research Institute, Kirkhill, Ayr, on April 30. It took the form of a symposium on "Minor Elements in Nutrition".

In his introductory remarks the chairman, Dr. D. P. Cuthbertson (Rowett Research Institute, Aberdeen), observed that during the past thirty years a steadily increasing number of mineral elements had been found as permanent constituents of plant and animal tissues. The biological functions of mineral elements present in relatively large amounts, the so-called 'major elements', were well defined, but the role of many of the minor elements in tissues was still, as yet, unknown. This might arise partly from the technical difficulties associated with estimating trace amounts of such elements; but with the increased use of modern techniques it is expected that some at least of these minor elements with an unknown function will be found to have an essential physiological role in the tissues.

For the purposes of this symposium, a minor element was defined as a metal generally belonging to the transitional group of the Periodic Table (iodine, fluorine and selenium being exceptions) which is present in the organism in concentrations of not more than 1 in 20,000, or 50 p.p.m., and serves therein an essential function as an oxygen carrier or in some enzyme system, hormone or vitamin.

The first paper, on "Trace Elements in Scottish Soils", was given by Dr. R. L. Mitchell (Macaulay Institute for Soil Research, Aberdeen). Dr. Mitchell pointed out that the realization of the importance of trace elements in animal nutrition had led to a requirement for maps or other means of ascertaining the probable trace element status of the soils of any locality. In contrast to regions with extensive areas of soils derived from uniform parent material such as the great continental plains, where the trace element status of the soil can often be related directly to pedological factors and can be readily mapped on small-scale maps, conditions in Scotland are much more complex and such generalization is impossible.

Scotland is an area of complex geology in which the parent rocks contain highly variable amounts of the biologically important trace elements, and several periods of glaciation have produced surface drift which further complicates the picture.

Dr. Mitchell then discussed the distribution of trace elements in soils and soil parent materials. Trace elements are located in major rock-forming minerals as a result of substitution for major elements of similar ionic radius in the crystal lattice. Elements of biological importance such as cobalt and copper tend to be concentrated in argillaceous sediments along with molybdenum and selenium. Sandstones and derived sandy soils often have low trace-element contents. The trace-element content of soils can be predicted from the parent material. Unlike the concentrations of major minerals, those of minor minerals can differ widely by a hundred or even a thousand times from soil to soil. A semiquantitative estimate of trace-mineral content or even the nature of the parent material will usually suffice for an assessment of soil status. The availability of trace elements is influenced by rate of weathering of soil minerals and pedological factors affecting the rate of weathering.

Uptake of available minerals by the plant is affected by agricultural practices such as liming, which alters the soil *p*H, and drainage. Under Scottish conditions drainage is the factor most influencing the mobilization of trace elements. With poor drainage there is a larger soil concentration of trace elements, and herbage contents of more than 10 p.p.m. molybdenum have been recorded under such conditions. Certain areas of Aberdeenshire are almost completely infertile owing to poor drainage and the accumulation of excessive quantities of extractable nickel in the soil.

Trace-element uptake by animals on herbage is related not only to soil factors such as those mentioned above but also to seasonal changes in plant composition, variation in the relative amounts of different species in the sward throughout the season, stage of maturity of the crop and climatic factors affecting growth.

In the second paper, Dr. E. C. Owen of the Hannah Dairy Research Institute, Ayr, discussed the "Biochemical Function of Some of the Minor Elements". Dr. Owen confined his remarks to cobalt, zinc, vanadium and manganese. As an essential part of vitamin B_{12}, cobalt is essential for non-ruminants to prevent anæmia and to ensure optimal growth on food of vegetable origin. Vitamin B_{12} can be synthesized by ruminants providing they are supplied with sufficient dietary cobalt. In addition, both ruminants and non-ruminants probably need cobalt in ionic form for the activity of a number of enzymes. After describing typical symptoms of cobalt deficiency in animals, Dr. Owen pointed out that people eating only food of vegetable origin run a special hazard in regard to vitamin B_{12} deficiency in that a high intake of folic acid from greenstuff raises the requirement for vitamin B_{12}. The distribution of vitamin B_{12} in Nature is consistent with a general belief that only bacteria can synthesize it from cobalt salts.

Zinc is a constituent of the carbonic anhydrase of bovine erythrocytes and certain organs of the body and of plant tissues. Carbonic anhydrase is inhibited by sulphonamide, but apparently not through the zinc of its molecule. Studies on the skin disease of pigs called parakeratosis show that high dietary calcium aggravates the condition probably by causing a more rapid turnover of zinc and thus raising the requirement. It is claimed that the effects of excess calcium can be nullified by adding citric or acetic acids to the ration.

It is of interest that pigs suffering from parakeratosis show more variable alkaline phosphatase activity than control pigs and that zinc has been suggested as a specific activator of alkaline phosphatase. Other enzyme systems associated with zinc are alcohol dehydrogenase of yeast and equine liver, glutamic dehydrogenase of bovine liver and lactic dehydrogenase of rabbit skeletal muscle. Dr. Owen thought that the turnover of zinc may be of more importance than the actual concentration in tissues.

In the third paper, Dr. C. F. Mills (Rowett Research Institute, Aberdeen) described "Comparative Studies of Copper, Molybdenum and Sulphur Metabolism in the Ruminant and the Rat". Dr. Mills pointed out that elevated levels of molybdenum and sulphate in the diet of the sheep gave rise to depletion of copper stores and the appearance of symptoms of copper deficiency. The mechanism of action of molybdenum and sulphate under these conditions is unknown. Studies with the rat have shown that high dietary molybdenum contents lead to reduced growth-rate, failure of hæmoglobin synthesis, and production of skeletal abnormalities. That this indicated an interference with normal copper metabolism was shown by increasing dietary copper levels and thus preventing the deleterious effects. It has further been shown that high dietary levels of molybdenum cause accumulation of copper in the liver of the rat. This is in marked contrast to the experience with sheep, where a *depletion* of tissue copper reserves usually occurs.

Excess dietary sulphate also has a contrasting effect when fed in high-molybdenum/low-copper diets. In sheep, increase in dietary sulphate precipitates a rapid decline in liver copper levels, but in the rat it prevents the abnormal accumulation of copper in the liver and improves the growth-rate, hæmoglobin development and skeletal development. In both rat and sheep, adding sulphate to the diet led to an increased output of urinary molybdenum and a fall in tissue molybdenum levels.

These marked species differences led to an investigation of the fate of sulphate in the digestive tract. In the ruminant, sulphide is formed rapidly by micro-organisms, and experiments on feeding molybdenum, sulphide and copper to rats in semi-synthetic diets were carried out. It was found that the sulphide oxidizing system of the rat liver was markedly depressed by feeding molybdate. This suggested that the detoxication of sulphide may be restricted in tissues high in molybdenum.

Among other enzyme systems found to be influenced by high dietary levels of molybdenum are alkaline phosphatase and liver cytochrome oxidase. In connexion with the latter, it is interesting to note that liver cytochrome oxidase activity may be drastically reduced in the copper-deficient rat.

Comparable work is in progress feeding sheep on diets enriched with molybdenum and sulphate. It would appear that the presence of molybdenum increases the rate of reduction of sulphate to sulphide in the rumen. The presence of molybdenum and sulphate depressed the content of soluble copper in the rumen and abomasum. These results might indicate the formation of insoluble copper sulphide, a poor source of copper for sheep.

However, the true significance of the increased sulphide levels in the rumen of sheep following ingestion of molybdenum, in relation to changes in soluble copper concentration, are not yet clear, and in current work to study this aspect the possibility of more extensive effects of molybdenum on sulphur metabolism in the digestive tract is being considered.

In his paper on "Selenium in Animal Health", Mr. G. A. M. Sharman (Veterinary Investigation Service, North of Scotland College of Agriculture, Aberdeen) observed that selenium was a relatively scarce element which was hard to estimate chemically. The lowest soil concentrations are expected in light soils derived from Old Red Sandstone, carboniferous sandstone rocks or certain granites. Concentrations of 0·05 p.p.m. or less might be expected in such soils and might well give rise to deficiency states in grazing animals. Relatively higher values are found in sedimentary rocks, certain shales having values as large as 0·25–1·2 p.p.m. There are certain areas in western Canada and the United States, Mexico, Colombia, Ireland, Israel and Australia where soils containing even higher contents of selenium are to be found, and because the vegetation is high in selenium there is a problem of toxicity among grazing animals. On such seleniferous soils plants absorb very little or a great deal of selenium from the soil depending on the species. Some plant species contain as much as a thousand times more selenium on the dry basis than the soil on which it was grown.

Selenium is the only element known to be absorbed by plants in sufficient amount to cause death from acute poisoning when eaten. For farm animals, dietary concentrations above 10 p.p.m. would appear to be lethal and for chicks a level of 1 p.p.m. produced definite changes in blood constituents. Ingestion of sub-lethal amounts of selenium for long periods leads to its accumulation in hair and hide. Chemical estimation in hair is therefore a guide to selenium status. Cattle from seleniferous areas had hair with selenium content ranging from 10 to 25 p.p.m. compared with the normal 1–4 p.p.m.

It has been shown recently that in rats, chicks and certain farm animals, symptoms of vitamin E deficiency may be alleviated by feeding traces of selenium, and in some cases selenium appears to be essential. New York workers have shown that rations containing 1·1 p.p.m. selenium fed to pregnant ewes prevented white muscle disease in lambs, whereas rations containing 0·01–0·08 p.p.m. did not. Similar experiences have been reported from elsewhere.

Enzootic muscular dystrophy in calves in the north of Scotland was cured by daily dosing with 0·25 mgm. selenium as selenate, or by weekly dosing with 200 mgm. α-tocopherol.

Mr. Sharman emphasized that selenium should not be added to commercial mineral mixtures for farm animals because of the small margin of safety between essential and toxic levels.

In the final paper, on "Adventitious Metals in Processed Foods", Miss E. M. Chatt (British Food Industries Research Association, Leatherhead, Surrey) directed attention to the rapid advances in food production, processing and technology which had taken place this century. She pointed out that increased production of flesh foods led to increased production of crops, giving rise to increased hazard from pests, which had to be controlled by chemical sprays or dusting. Some of these methods of chemical control give rise to contamination with toxic metals which can persist and be carried over into the finished product. Adventitious metals may be present therefore in many raw materials before they arrive at a factory for processing, and in the factory further contamination is liable to occur. In the case of canned foods, contamination also occurs by absorption of tin and iron during storage.

In drawing up recommendations for limits of traces of metals in foods the Food Standards Committee of the Ministry of Agriculture, Fisheries and Food is guided by what is judged to be good commercial practice. All paint in factories should be lead-free and of the rust-resisting variety. Condensation should be avoided by suitable factory design. Equipment should preferably be made from metals not readily subject to abrasion, such as stainless steel. Miss Chatt gave many examples of ways of avoiding contamination, including methods of inspection and the manufacture and lacquering of cans, and also gave a comprehensive list of the commoner metallic contaminants sometimes encountered in foods—arsenic, lead, copper, zinc, iron, nickel, mercury and antimony.

J. Davidson

NITROGEN IN TROPICAL AGRICULTURE

A SYMPOSIUM on nitrogen in tropical agriculture was held in Brisbane during February 23–24. It was organized by the Commonwealth Scientific and Industrial Research Organization at the Cunningham Laboratory, the headquarters of the Division of Tropical Pastures. Although the majority of the papers were by officers of the Organization, several other organizations concerned with research in agricultural and pastoral industries in tropical Australia also contributed.

In his foreword to the conference proceedings, Dr. J. G. Davies (chief of the Division of Tropical Pastures) described the objective of the symposium as "to review existing information on the role of nitrogen in the agriculture of the tropics and sub-tropics, with emphasis on those aspects which are relevant to the problems of northern Australia and Queensland in particular".

The symposium was highly successful on two counts: it brought together under ready reference a number of reviews on topics of the utmost importance to the future development of tropical agriculture, and equally significant, the papers and discussions demonstrated many serious gaps in information on the role of nitrogen in the tropics and showed where further research is required.

Four papers in Session 1 (general problems of nitrogen economy) dealt with the processes by which nitrogen is gained and lost by the soil/plant system and with the nitrogen economics of natural plant communities and the grazing ruminant animal. D. O. Norris and E. F. Henzell, who considered the processes by which nitrogen is added to the soil/plant system, emphasized the widespread nature and importance of nitrogen deficiency in limiting pasture and crop production in the tropics and concluded that, despite the difficulty of estimating the efficiency of fixation, there was evidence that tropical legumes, under favourable conditions, were equal if not superior to temperate legumes as nitrogen fixers. A. E. Martin and G. W. Skyring dealt with losses of nitrogen from the soil/plant system, listing leaching, crops, erosion, fire and volatilization as factors involved. They considered that some of the losses due to leaching, and most of the losses of gaseous nitrogen reported in the literature, were exaggerated, and suggested that the standard analytical techniques were likely to give lower gains and higher losses of nitrogen than were, in fact, experienced. J. E. Coaldrake emphasized the much slower turnover of nitrogen in natural communities compared with pastures, and joined with Norris and Henzell in pointing out that important accretions of nitrogen came from non-legumes. In reviewing the nitrogen intake and excretion of grazing animals, I. W. McDonald discussed the varied requirements of different classes of ruminant animal, stressing that they retained, on average, only 15 per cent of ingested nitrogen. Discussion topics included the possible importance of free-living nitrogen-fixing organisms in the nitrogen economy of the tropics and the need to ascertain the nitrogen requirements of ruminant animals in tropical environments.

Session 2 (soil nitrogen) consisted of three papers on nitrogen status and nitrogen transformations in soil. G. D. Hubble and A. E. Martin described the nitrogen status of Queensland soils and noted similar modal nitrogen contents in soils from northern and southern Australia (both of which were less than for East African soils); it was apparent that the total nitrogen of surface soils in Queensland was more highly correlated with total phosphate than with annual rainfall. G. W. Skyring and Barbara J. Carey described the microbial species involved in nitrification and denitrification, their physiology and biochemistry and techniques of isolating and culturing them. Although denitrification occurred in apparently well-aerated soil, no denitrification was detectable in cultures containing measurable quantities of oxygen. Nitrogen transformations in soil were considered by A. E. Martin, who referred to recent tracer work with nitrogen-15 in the United States and Sweden which had shown that mineralization and immobilization of nitrogen were simultaneous processes; only net effects had hitherto been measured. He noted that, while ammonia was important, nitrate was not necessary to the microbial cycle. Important topics in discussion were the factors promoting and inhibiting nitrate formation, the carbon/nitrogen ratio and its indication of soil nitrogen availability, and methods of determining the availability of soil nitrogen. Instances were quoted where, although 80 per cent of the nitrogen present in the original rain forest vegetation remained in the soil, nitrogen shortage was still severely limiting pasture growth.

Session 3 (nitrogen fixation) contained two papers. D. O. Norris, in his review of the biology of nitrogen fixation, showed that the classical temperate legume/rhizobium symbiosis was atypical of the Leguminosae as a whole, which were essentially of tropical origin; he also emphasized the wide range of plants and bacteria involved in fixation. C. S. Andrew considered the growth of legumes in acid soils and used this criterion as a measure of symbiotic efficiency. The use of plants other than conventional herbaceous legumes, for example, blue-green algae or nodulating non-legumes, to build up nitrogen in the system was discussed. The mechanism by which phosphate stimulated nodulation also received attention.

Two papers in Session 4 (plant nitrogen) dealt with the pathways and processes of nitrogen metabolism in plants. Protein synthesis was the main theme of M. P. Hegarty's paper on nitrogen uptake and transformations. He reviewed the evidence pointing to ammonia as a key intermediate and described the primary synthesis of amino-acids and their subsequent elaboration. Interference with amino-acid metabolism caused by mineral deficiency was described by R. G. Coleman. He showed that mineral deficiency was frequently associated with disruption of enzyme activity; amino-acids may accumulate, and symptoms of deficiency result. Discussion emphasized the complexity of mineral imbalance which could affect the level of other nitrogen compounds, for example, purines and pyrimidines, as well as amino-acids. The comparative insensitivity of ruminant animals to changes in the proportions of nitrogen compounds in their diet was attributed to the profound modifications brought about by microbial metabolism in the rumen.

Session 5 (nitrogen for crops) contained five papers. I. F. Phipps described the manufacture and use of nitrogenous fertilizers, dealing chiefly with Australia, where about 125,000 tons were used annually, mostly in the form of ammonium sulphate, although the popularity of urea was increasing. The papers on nitrogen fertilizing of crops were by L. G. Vallance (sugar), F. Chippendale (tobacco and horticultural crops), W. J. Cartmill (cotton) and S. A. Waring (grain and forage crops). One hundredweight of ammonium sulphate increased the yield of sugar by 25 hundredweight in Australia: the highest commercial application was 5 hundredweight ammonium sulphate per acre. There was considerable disagreement about the effects of different sources of nitrogen on tobacco quality, although the nitrate form was favoured in Queensland. With cotton in Queensland, responses to nitrogen were related to moisture availability; best results had been achieved where nitrogen fertilizer and irrigation were combined. Among possible adverse effects from nitrogen fertilization of grain crops were lodging, excessive nitrogen content in malting barley, and actual yield depression with droughted sorghum. Delegates spoke of the different soil depths exploited by different forage crops, the superiority of slow-acting nitrogenous fertilizers for some crops, and the growing popularity of urea as a source of nitrogen.

Session 6 (nitrogen for pastures) comprised two paper on sources of nitrogen, both including consideration of the influence of the grazing animal. W. W. Bryan considered the three symbioses legume/rhizobium, legume/grass and pasture/herbivore. World information on these relationships was almost wholly confined to temperate conditions; because of the many important differences of the tropical environment, a thorough study of these symbioses in the tropics was needed. Discussion revealed conflicting points of view on the importance and duration of the effects of nitrogen voided by the grazing animal. The need for perennial legumes capable of exploiting an improved soil environment, further information on native tropical pasture legumes as nitrogen donors and fundamental data on the mechanism of legume adaptation to difficult environments was emphasized. In reviewing the use of nitrogen fertilizer on pastures, E. F. Henzell pointed out that the widespread nature of nitrogen deficiency in tropical regions was accentuated by the lack of pasture legumes. There was a number of grass species with a growth potential appreciably greater than temperate grasses when nutrition was adequate. Because of the relatively low returns from pastoral farming and the high cost of nitrogenous fertilizers, insignificant quantities were now used on tropical pastures.

Discussion at the symposium inevitably dwelt on the fact that data applicable to the tropical environment were sadly lacking in such diverse fields as pasture utilization, nitrogen fixation by free-living organisms, soil nitrogen availability and the nitrogen metabolism and requirements of tropical pasture and crop plants. Those participating, most of whom were actively engaged in research on these and related fields, expressed the hope that the symposium would help to focus attention on the important problems of nitrogen in tropical agriculture.

A. G. EYLES

RHEOLOGY IN AUSTRALIA

A SYMPOSIUM on "Visco-Elastic Systems" was held during February 16–18 at the Division of Forest Products, Commonwealth Scientific and Industrial Research Organization, Melbourne. Organized by the host laboratory, the meeting was attended by more than fifty delegates from universities, industrial concerns and research institutes, and it foreshadowed some of the activities of the nascent Australian branch of the British Society of Rheology.

Opening the conference, Dr. F. W. G. White, chairman of the Organization, stressed the need to place industrial activity on the most mature and fundamental scientific basis. He welcomed the move to form a rheological society in Australia, which would provide more opportunity for co-operation on common problems in different scientific fields.

The topics were grouped into six sections. In the first of these, "Structural Interpretation", B. J. Rigby reviewed theories of rate processes, and illustrated the use of the Burte-Halsey theory by its application to the rheological behaviour of wool. R. S. T. Kingston applied rate-process theory to the analysis of time-dependent mechanical behaviour of wood at high stresses. A qualitative change in the flow process was indicated by a stress region where energy constants underwent sudden changes.

H. G. Higgins presented a theoretical account of the behaviour of hydrogen-bonded materials, based on the work of Prof. A. H. Nissan. Chemical substitution of hydroxyl groups in cellulose can confirm the basic assumption that the mechanical response is controlled by the number of hydrogen bonds per unit volume. Dr. N. W. Tschoegl gave an account of his studies on monomolecular cereal protein films. The influence of the substrate on the visco-elastic properties of the film yields much information on the nature of bonding in the film. A. W. McKenzie discussed the influence of inter-fibre bonding in a paper on the tensile stress-strain behaviour. A qualitative change in the orientation of fractures with increased bonding is interpreted as an increase in shear strength relative to tensile strength. R. C. Gifkins, after briefly surveying the subject of deformations in crystals, suggested that apparent viscous relaxation in grain boundaries may be an interaction of dislocations and vacancies, that is, a discontinuous crystalline process.

In the second section, "Heterogeneous Systems", Dr. F. A. Blakey discussed the relative contribution of the cement paste and of the aggregate to the creep of concrete. J. De Yong, in a paper with H. G. Higgins, described draining studies on a pad of cellulose fibres, representing an early stage of paper formation. Compressibility of the porous medium complicates both the Kozeny and the drag equations. L. Dintenfass presented a rheological classification of suspensions, separating the properties of the solid and the liquid phases. He correlated colloidal structural properties such as sedimentation volume with the flow-curves of paints and other systems.

In the following section, "Hygroplasticity", several papers were devoted to wood and one to wool. Dr. G. N. Christensen described the effect of rheological properties on sorption. He had observed that the rate of water sorption by thin layers of wood is inconsistent with diffusion control, and suggested it might be dependent on the relaxation of swelling stresses. Two important practical effects arising on drying wood, namely, 'collapse' and 'set', formed the subject of a paper by Dr. W. G. Kauman, who correlated macroscopic observations with the molecular processes in the cell wall. M. Feughelman discussed the effect of humidity on stress relaxation in wool, and suggested a model in which hydrogen bonds break in the presence of 'mobile' water. L. D. Armstrong presented experimental evidence on the great increase in creep of wood when changes in moisture content take place while the material is loaded. The influence of changes in moisture content was also observed by J. W. Gottstein, who used strips of wood veneer held at constant deformation and subjected to humidity cycles.

The fourth section was concerned with "Specific Materials". Dr. F. A. Blakey reviewed factors influencing the creep of gypsum plaster, and again emphasized the effect of free moisture content on the stress-strain-time relations. Various practical requirements of glazing compounds were discussed by E. R. Ballantyne, who compared the properties of oil-based and rubber-based compounds. C. Massey described tests on several thermoplastics with reference to their suitability for model structural analysis.

In a section on "Instruments", Dr. B. I. Aldrich, in a joint paper with E. L. Newman, described a Couette viscometer designed for testing syrup during fractionation; it accommodates a wide range of shear stresses and has close temperature control. K. G. Martin described a micro-viscometer and discussed factors in its operation.

"Continuum Theory" was the subject of the last section. Dr. P. U. A. Grossman discussed Prof. K. Weissenberg's ideas leading from an assumed restriction on stress directions for a given strain history to observable phenomena, such as cross-stresses.

A policy session was held, at which the possibility of future co-operation in the field of rheology was discussed. In New South Wales the branch of the Society of Rheology has already held several meetings and has arranged a full programme of activities for the current year, including lecture courses on rheology. Plans were discussed for broadening the interest in this field, and for holding future meetings both at the local and national level.

P. U. A. Grossman

GAS CHROMATOGRAPHY

The Gas Chromatography Discussion Group of the Institute of Petroleum Hydrocarbon Research Group held its annual general meeting in conjunction with an informal symposium at the Brunel College of Technology, Acton, London, W.3, on April 22. The secretary, Mr. D. H. Desty, reported that the Group had had another successful year in which it consolidated its position following the rapid expansion of the past few years. Interest in the Group's activities has been well maintained and its status in the field is now well recognized on an international basis.

The abstracting service organized by the Group has made rapid progress, and more than 100 British and foreign journals are abstracted regularly by a team of 25 abstractors. The inaugural volume of "Gas Chromatography Abstracts", 1958, was published by Butterworths, London, on May 5, and has largely been the work of Mr. C. E. H. Knapman, the editor of the Group's editorial committee. This volume provides abstracts and, more particularly, a detailed subject index for 1,468 papers in this field published up to January 1, 1959. Succeeding volumes will appear annually.

Dr. A. T. James and Dr. D. Ambrose have taken part in the preparation by an international committee of preliminary recommendations on the nomenclature and presentation of gas chromatographic data, which were presented to the Analytical Section of the International Union of Pure and Applied Chemistry in September, 1959. These have now been approved in the International Union for publication. The Group's financial position is very sound, and its financial year has been adjusted to coincide with that of the Institute of Petroleum Hydrocarbon Research Group (that is, to the end of September). No change in the annual fee (1 guinea), which is now primarily intended to cover the cost of publications issued by the Group, is therefore necessary.

The informal symposium which followed the annual general meeting was organized and introduced by Dr. J. A. Skellon of Brunel College of Technology, who commented on the active research interests of the College in the field of gas chromatography. The first paper, and perhaps the highlight of the meeting, was that by Dr. J. H. Purnell on the modification of solid supports. Dr. Purnell described measurements, made in his laboratory, of the adsorptive properties of 'Celite' and brick dust which show that whereas 'Celite' has the lower adsorption, brick dust has the more reproducible properties. These experiments were made with the view of studying treatments of the support which might reduce adsorption and minimize tailing of peaks. One promising method of treatment is the use of hexamethyldisilazane, which reacts with hydroxyl groups. Its practical application is simple and the treated support is unwettable and has reduced adsorption. Although chromatograms obtained on the treated support are improved, a further improvement is obtained if 0·1 per cent polyethylene glycol is added to the column with the stationary phase. One disturbing fact is that treatment of the support in this way has a slight effect on values of the specific retention volume even when the columns contain as much as 20 per cent of stationary phase.

The other contributions to the meeting concerned the study of pyrolysis products. Dr. J. Girling described studies on the identification of the primary products of the pyrolysis of coal, in which field the introduction of gas chromatography has enabled the scale of experiments to be reduced from 20 kgm. to 20 mgm. A 20-mgm. sample is heated to a series of steady temperatures ranging from 50° up to 700° C. and the products of pyrolysis at each temperature are swept into a refrigerated trap. The analytical sample is injected on to the column, containing polyethyleneglycol or squalane, by means of an automatic valve of 0·1 ml. capacity; there was considerable interest in the design of this valve, the fixed sample volume of which is formed by a length of 1-mm. bore nylon tubing between two sections of the tubing which are compressed by cam-operated plungers. Dr. J. Blenkin described the analysis of hydrocarbon elastomers by combined pyrolysis and gas chromatography. It was hoped that elastomers could be identified if the monomers from which they are made could be obtained from them and analysed by gas chromatography: to a large extent this hope has been realized. Samples are pyrolysed by dropping them into a heated silica tube attached to the apparatus, so that the products of pyrolysis are swept into the column and chromatographed; for example, polybutadiene gives a chromatogram of butadiene, natural rubber one of a mixture of isoprene and dipentene. Dr. Lehrle described similar experiments in which the degradation was carried out in stages. A sample is placed in a coil of resistance wire in the form of a basket which is located at the entrance to the column. The temperature of the wire is varied by altering the current passing through it, and within half an hour a series of chromatograms can be obtained corresponding to the degradation of the one sample at each temperature. The series of chromatograms is characteristic and suitable for qualitative and quantitative analysis.

The symposium concluded with a general discussion on sample injection, which was introduced by Dr. Purnell. Most speakers were agreed on the difficulty, if not present impossibility, of injecting representative samples for quantitative analysis which are small enough to be satisfactory with ionization detectors. The lower limit of sample introduction possible with pipettes and syringes is probably about 25 micrograms. Various suggestions—for designs of valves or introduction of the sample in solution—were made, but the simplest proposal for quantitative analysis was made by Dr. A. B. Littlewood, namely, to use a large sample and correspondingly insensitive detector.

D. AMBROSE

MEDICAL RESEARCH IN MALAYA

THE valuable research work being done in the vast field of tropical medicine is well brought out in the annual report of the Institute for Medical Research, Federation of Malaya, for 1958.

The Institute is divided into a number of divisions, each of which is carrying out investigations into diseases which are baffling and wide-spread. In the Pathology Division, for example, a curious type of allergic granuloma, apparently hitherto undescribed and believed to be the result of an auto-immunity reaction, has been investigated for some years. The variations in the behaviour of melanocytes when surrounded by atypical or malignant epidermal cells have also been studied.

A number of important investigations are being made in the Division of Nutrition and Biochemistry. Severe anæmia is one of the main complications of pregnancy in Asian women, and one in eight of the beds available for ante-natal patients in the General Hospital, Kuala Lumpur, is occupied by a patient requiring treatment for anæmia. Premature births, deaths of infants and of mothers were all increased in this group of women.

The relationship of hookworm infection to anæmia was also studied: the greater the degree of anæmia, the higher was the proportion of patients with hookworm infection. The use of radioactive chromium enabled calculations of the daily loss of blood apparently due to hookworms; with heavy infections this could amount to as much as 80 ml. (almost 3 fl. oz.) of blood a day. Other studies were made on the changes in blood volume in chronic anæmia, on the factors influencing response to treatment, and on the reasons for the frequent low levels of vitamin B_{12} to be found in patients with megaloblastic anæmia.

Dietary inquiries made in the homes of a number of the patients indicated that various causes, besides poverty, were responsible for the poor diets which finally resulted in their admission to hospital with nutritional anæmia.

In almost every area where sufficient numbers of 'toddlers', children aged 1–4 years, have been examined, examples of protein malnutrition can be found; this is true even in the heart of Kuala Lumpur. Only a few come to hospital; they must be sought out by home visits and detailed inquiries. As might be expected, the condition is most common in isolated areas where communications are poor and unemployment is prevalent. A detailed investigation was made of kampongs on the Perak River where protein malnutrition is common; the diets there were found to be most unsatisfactory, and well below the recommended allowances.

In the Bacteriology and Serology Division, research activities were directed to the production of vaccines to combat epidemics of cholera and smallpox.

The search for Malayan streptomyces which may produce antibiotics continued, but without success; resistance of bacteria to the commonly used antibiotics is becoming more noticeable.

Resistance to the tubercle bacillus is now reaching the point where it presents a serious problem. Judging by sensitivity tests, about 10 per cent of local strains are completely resistant to streptomycin, about 10 per cent are resistant to *p*-aminosalicylate, and 2 per cent to isoniazid. Partial resistance to one or other of these drugs is found in 30–50 per cent of strains tested.

The Virus Research and Medical Zoology Division continued its work on arthropod-borne and other viruses. Further work was done on the survey of animal reservoirs of leptospirosis, and infected rats were obtained from Maxwell Hill in Perak, from Langkawi Island, and from parts of Trengganu. By contrast, no infections were found in much larger numbers of rats from Selangor coastal region. A new development, still being investigated, was the finding of evidence of frequent infection in one but not another species of water-snake in Kuala Lumpur streams.

Leptospirosis in humans is now recognized as being much more common than had been suspected a few years ago, and the virus laboratory is at present trying to assess the diagnostic value of a relatively simple test, suitable for use in a routine laboratory.

At the request of the World Health Organization, the Entomology Division carried out tests to assess the merits of two types of apparatus in which mosquitoes are held for short periods against surfaces treated with insecticide, and the kill later recorded. The opportunity was taken to include the organo-phosphorus compound, malathion, in these tests: the duration of effectiveness proved to be about three months, which was longer than had been expected. The importance of this finding is that malathion has had to be used to control bed bugs which have developed resistance to the usual residual insecticides, especially dieldrin. Reports of such resistance were received from three rubber estates and a small mental hospital, and malathion is reported to have given satisfactory results.

An incidental result of house-spraying with dieldrin has been the virtual elimination of head-lice in the children living in the sprayed houses. Whereas in unsprayed areas infestation-rates in both boys and girls were 70–90 per cent, no active infestation could be found in the children where spraying had been carried out for one year.

Other work done at the Institute was by the U.S. Army Medical Research Unit, Malaya. The unit investigated two outbreaks of scrub typhus in the Commonwealth Forces in some detail. One in central Perak, near Ipoh, was unusual in that the disease was mild, the Weil–Felix reactions were negative, and cases occurred in forest during the dry season instead of in scrub terrain in the wet season. *Rickettsiae*, however, were isolated in mice inoculated with blood from several patients, and they appear to belong to the scrub typhus group. Cases from the other outbreak in south-east Johore were typical in nature, and Weil–Felix tests were positive.

The report may be obtained from the Director of Medical Research, Federation of Malaya, Kuala Lumpur.

SURFACE TEMPERATURE OF SWEDISH LAKES AND THE ORIGIN OF RAINFALL

By VILHELM IRGENS PETTERSSON*
Bollstavägen 10, Enskede, Sweden

The Dry Summer of 1959

THE accompanying diagrams (Figs. 1–4) give the distribution of rainfall over Sweden as a percentage of the normal in 1959 (published by the Meteorological and Hydrological Institute of Stockholm). They show very clearly that in the summer of 1959 Sweden shared the scarcity of rainfall characterizing the weather over most of north-western Europe, although it varied from place to place. As will be seen, the whole inland area, generally speaking, with its half-dried-out rivers and reduced crops, is framed in by belts of moisture along the coasts and the Norwegian and the Finnish borders, broadening to their maximum in the north.

The period of deficit in rainfall over the major part of Sweden lasted for the five months May–September, according to the monthly surveys of the Meteorological and Hydrological Institute in Stockholm, from which the following data are cited:

May. Total precipitation averaged 87 per cent of normal, with sub-variations of 300 per cent in the north down to 10 per cent in the south.

June. Total precipitation averaged 61 per cent of normal with sub-variations of surplus in the north and deficit in the south with its minimum in the middle south-west.

July. Precipitation in general 72 per cent of normal with a minimum of 10–25 per cent in the northern Baltic coast-land.

August. Precipitation in general 41 per cent of normal; 100 per cent only in limited areas in farthest north and south.

September. Precipitation as total average 53 per cent of normal except along the northern part of the Norwegian border, and in a belt running east–west from south of Lake Vanern to the coast south of Stockholm with a rainfall 100–200 per cent of normal.

Note. In the following, temperatures are in degrees centigrade, distances and depths are in kilometres and metres respectively; surface temperatures were measured 0·5–1·0 m. beneath the surface.

Rainfall South of lat. 59° 30′ N. and Deviations in Temperature from the Average during July–September 1959

In this part of Sweden the landscape is dominated by the two big lakes, Lake Vänern with an area of 5,500 km.^{2}, and Lake Vettern with an area of 1,900 km.^{2}.

July (Fig. 1). The average temperature was 2°–2·5° above normal; precipitation 100 per cent and more only in the south inside a triangular area with its base along the Öresund and farther east to the south point of the island of Öland, reaching up to the south end of Lake Vettern; this lake, together with the north part of Lake Vänern falling inside the contour for 50–75 per cent of rainfall, the south part of Lake Vänern again being inside a region of almost total dryness.

August (Fig. 2). Average temperature was 2°–3° above normal. Precipitation was 10–50 per cent of the average. It was up to normal only in isolated areas, one of them around the south end of Lake Vettern whereas Lake Vänern registered 25 per cent and less.

---

[*] Formerly of the Service Hydrographique in Copenhagen and editor of its *Bulletin Trimestriel*.

September (Fig. 3). Average temperature was 0·5°–1·5° above normal. Precipitation was only 10–50 per cent of the average except inside a broad belt of 100–200 per cent of normal stretching from a region south of Lake Vanern eastwards, covering Lake Vettern and farther east passing the Baltic to the island of Gotland, its southern border touching the north point of the island of Öland.

Probable Cause for Heterogeneous Distribution of Rainfall

A study of the diagrams for July–September gives the impression that the surface of Lake Vettern, in the midst of an almost dried-out inland area, exercises a sort of attraction on the contours encircling areas of increased rainfall (July) in some cases being more or less included therein (August–September); by contrast, the surface of Lake Vánern, its neighbour to the west, is generally speaking, avoided by the contours, and in some cases came partly inside regions of almost total dryness (July–August). In order to explain this difference we have to look into the hydrographical conditions characterizing the two lakes.

Lake Vanern. The surface of this lake is a quadrilateral figure of about 70 km. × 70 km. apart from a peninsula cutting into it from the north-west. Its bottom topography over the major part of its area is more or less a plane from 20–40 m. beneath the surface, and sloping slightly west- and northwards where in isolated places depths up to some 90 m. have been sounded. The water in this shallow basin in periods of intense insolation during the summer months easily attains a surface temperature of 20° and higher, which has been the case for months in the hot summer of 1959. Measurements then undertaken in the middle of July by the Meteorological and Hydrological Institute showed a surface temperature of 19·3°.

Table 1

east border at Motala. Its east and west borders slope down to meet in the bottom of the groove at a depth of some 100 m. running parallel to and some kilometres east of the longitudinal axis of the lake almost from end to end. The water of Lake Vettern is remarkable for its low surface temperature in summer relative to that of Lake Vanern, and also for the perfect clearness of its water, the neighbouring towns taking drinking water by pipe-lines from the Lake. Temperatures were recorded at four points along the borders of Lake Vettern in July 1959 by the Ice Service of the Meteorological and Hydrological Institute. The points of observations were (Table 1); western border: (1) Karlsborg, lat. 53° 30′ N.; (2) Hjo, lat. 53° 15′ N.; southern end of the Lake: (3) Jonköping; eastern border: (4) Gränna, lat. 58° N.

The variations in surface temperature of Lake Vettern in a period of intense insolation giving an average of at least 4° below that of Lake Vänern are caused by a mixing of the sun-heated surface with colder water from the deeper layers, due to a continuous vertical circulation both ways. The prime agent effecting this is the wind by its tangential pressure on the surface layer, particularly since its direction crosses the Lake perpendicular to its longitudinal axis, namely, east–west and vice versa. The water on the surface thus driven away from the windward border towards the lee border, making colder water from beneath rise and mix with the warmer upper layer, effects a reduction in its temperature. In consequence the surface temperature in Lake Vettern as a rule is higher at the lee and lower at the windward border.

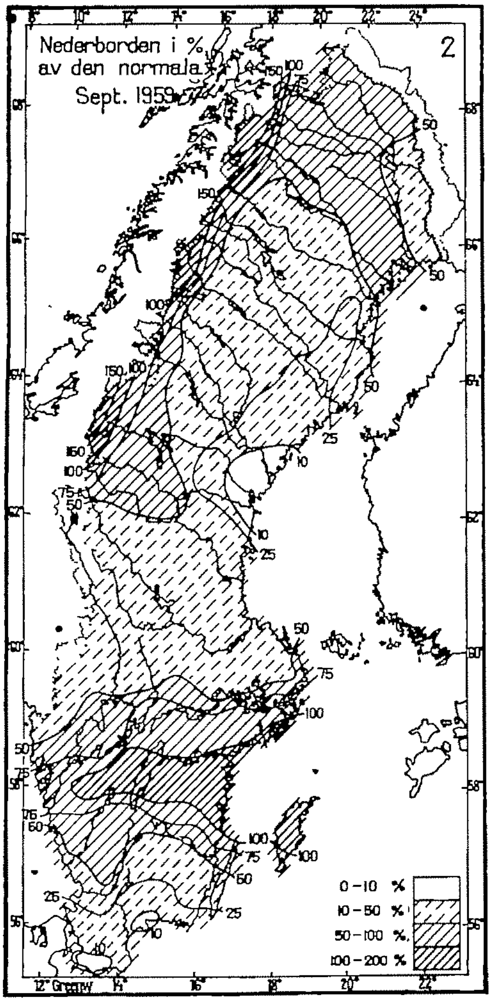

Fig. 3. September

Incidentally, the same phenomenon on a gigantic scale takes place off the west coast of North Africa, where the hot winds from the Sahara always blowing westwards drive the surface layer out from the coast, thereby allowing cold water from the deeper layers to rise to the surface. As a consequence, this part of the North Atlantic has its surface temperature reduced to less than 20° and even to some 16° as far west as the Canaries.

But the tangential pressure on the surface layer, when directed instead more or less parallel to the longitudinal axis of the Lake, namely, north–south or vice versa, drives the water from one end towards the other and makes the water-level rise at the lee and sink at the windward end—which on a reduced scale takes place also in the first case—and gives rise to another phenomenon known as the 'seiches of Lake Vettern'. This phenomenon was studied in the early part of the present century by Dr. F. Bergsten and published by him in a treatise under that title. By bringing the water-level out of balance, the whole bulk of some 80 km.^{3}—some 80 billion tons of water—is set swinging like a gigantic rocking chair on a nodal axis half-way between the ends of the Lake where the movement is nil, increasing to its maximum at either end, the water-level here alternately rising and falling with the same amplitude relative to the horizontal plane. This phenomenon is characteristic especially of oblong lakes and was first studied by Forel in Lake Leman and later by Chrystal and Maclagan-Wedderburn in the Scottish Lochs Earn and Treig. Dr. Bergsten based his work on the methods elaborated by Chrystal and found the seiches of uninodal order in Lake Vettern to have a maximal amplitude of 13 cm. and a frequency, that is, time between oscillations, of 174–180 min.

Variations in barometric pressure have also been found under certain conditions to influence the formation of seiches caused by the winds, for example, when minima pass parallel to its longitudinal axis.

To ascertain the difference in surface temperature between Lake Vettern and the sea areas east and west of southern Sweden swept by the winds before passing over the district of the big lakes, observations from the series registered daily on the Swedish light-vessels *Svenska Bjorn* in the Baltic east of Stockholm and *Vinga* west of Gothenburg for July–September are given in Table 2. The corresponding observations for November are also given, representing a later

period of another thermal character to be dealt with later.

The cold surface of Lake Vettern, almost 2,000 km.[2] in area and situated in the midst of a depression in the highland plateau of southern Sweden, will in hot summers continuously build up a 'mound' of cooled air, making the warmer winds ascend and unload their moisture as shown by the curves of Figs. 1–3 in accordance with the theory of Vilhelm Bjerknes.

The above data from the Baltic and the Skagerak for August 1959 compared with the average values calculated by the Deutsche Seewarte in Hamburg represent a surplus of 3–4 deg., whereas the surface layer of the Baltic in ordinary summers is cooled by the outflow from the rivers in the north transporting water from the melting snow in the mountains of Sweden and Finland. Its total mass, holding a few parts per thousand of salt from a bottom current entering by the Belts from the Kattegat, like a gigantic river is perpetually moving south to its outflow through the Belts and the Öresund into the Kattegat at a yearly quantity calculated by Witting as about 430 km.[3]. Presumably the total for 1959 will undergo a considerable reduction because of the scarcity of rainfall over the Baltic and the diminished influx from the rivers where the low water-level has made timber-floating almost impossible.

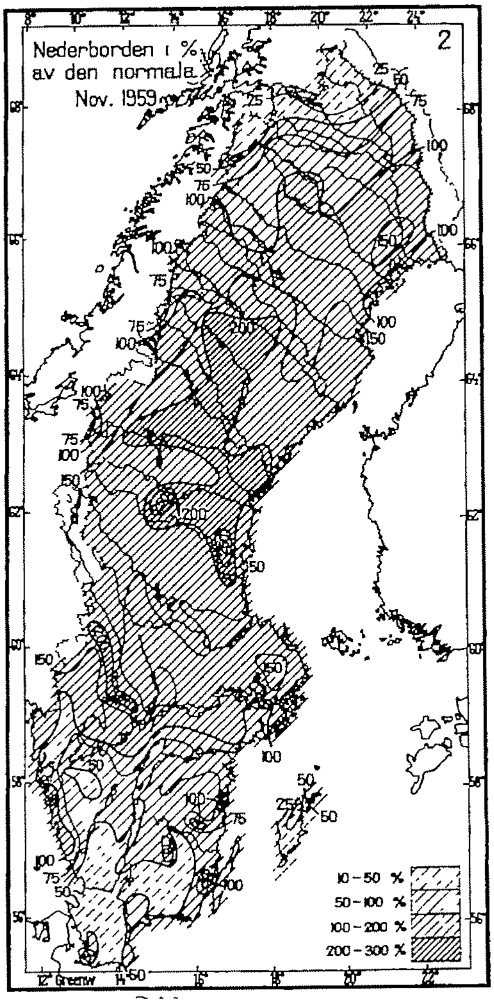

Fig. 4. November

An open question is whether the continuous damming up of river water for bigger and bigger hydro-electric plants for supplying electric power in winter does indeed cause a noteworthy reduction in the summer outflow into the Baltic. This, in periods of intensified insolation, would tend to increase its surface temperature.

The Situation in November 1959

According to the monthly meteorological survey, the average temperature south of lat. 59° 30′ N., steadily sinking from September, still shows an excess above normal of 1–2 deg. Only in isolated places did precipitation amount to normal, in spite of the abundant rainfall of up to 200 per cent and more in middle and northern Sweden north of the curve for 100 per cent rainfall running east-west and including the major part of Lake Vänern in that area, but leaving Lake Vettern south of it in a rainfall area of 75 per cent of the average and extending its southern end into an offshoot from an area of maximal scarcity in the farthest south.

Thus in November, both Lakes seem to have exchanged their former character of attractiveness or the opposite on the curves of increased precipitation. Surface data for Lake Vänern, however, could not be obtained, but by a lucky chance temperatures for Lake Vettern in November have been supplied by courtesy of Chief Engineer G. Wigforss of Motala, being registered at 4 m. beneath the surface at a point 500 m. west of Motala at the eastern border where Mr. Wigforss wanted for a special purpose to ascertain the thermal development.

Table 3 shows the temperatures together with (*a*) the direction and velocity of the wind, because as already mentioned they influence indirectly the variations in surface temperature and (*b*) for comparison also data for the Baltic and the Skagerak.

The reason for accepting data at a depth of 4 m. as representative for the surface is that the direction of the wind is alternately from either border, thus shifting between windward and lee. The temperature of the former being expected to sink and the latter to rise will give a medium value at 4 m. of satisfactory accuracy for the purpose of a comparison with that of the sea surface.

The results indicate that the usual reduction in surface temperature during September has taken place at a slower rate in Lake Vettern than in the sea east and west, resulting in an equilibrium in November. This explains the disappearance of any tendency to start a moisture condensation from the air above or in the vicinity of the Lake, contrary to the situation in the preceding months.

Discussion

The present work indicates an equivalence between the temperature of the sea surface on either side of

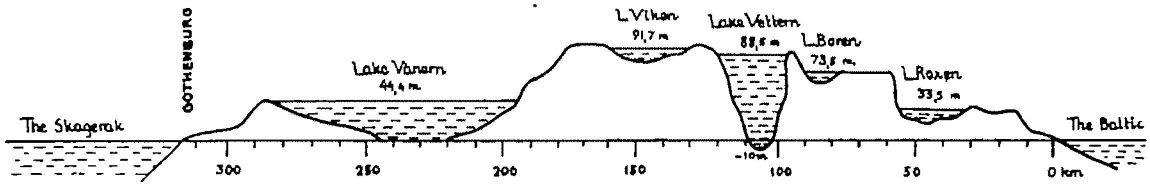

Fig. 5

Sweden in the summer of 1959 and that of the continental and Atlantic winds sweeping it, in contrast to the difference in ordinary years prevailing between the cooler surface of the Baltic and the Skagerak relative to the warmer atmosphere above. Application of the thesis formulated by Otto Pettersson from a climatic point of view leads to the conclusion that this balance in the thermal state explains the scarcity of rainfall over the major part of Sweden during the summer of 1959, the invading winds from south and west not unloading their moisture until attacking the cold wall of the polar front, apparently established farther north than in ordinary years when July statistically holds the year's record in rainfall.

The apparent activating influence by the colder surface of Lake Vettern on condensation of moisture in the air above it during July–September is also in agreement with this thesis, as well as the simultaneous scarcity in rainfall over and in the vicinity of Lake Vänern, then presumably of a temperature equal to that of the sea surface to the east and west. Hence the occurrence of cold and moist summers, at least in south and middle Sweden up to a certain elevation above the sea-level, will be directly related to a difference in surface temperature between the Baltic and the Skagerak and the warmer winds from the south and west, depending on or in connexion with an extension to the south of the polar front, a problem which was attacked from a cosmic point of view by Otto Pettersson in his lecture referred to above.

Fig. 5 gives the profile of a vertical section of southern Sweden following the course of the Göta Canal and cutting the highland plateau between the Baltic and the Skagerak, on its way crossing both Lakes Vettern and Vänern. As will be seen, the surface of the latter is 44·4 m. above the sea surface whereas that of Lake Vettern reaches 88·5 m. above and the deepest part of its bottom groove some 10 m. below, its maximal depth thus amounting to about 100 m. (Lake Vettern, however, is very shallow compared with the biggest Norwegian lake, Lake Mjösa, only 359 km.^{2} in area but with a maximal depth of 443 m., of which no less than 322 m. is below and 121 m. above the surface of the North Sea.) For the exact middle water-level in the respective lakes I am indebted to the directors of the Göta Kanal Co., Ltd., through Colonel B. Klint, Motala.

The significance of hydrography for meteorological forecasting cannot be over-emphasized, provided that the necessary data, especially regarding surface temperature from the actual sea areas, can be provided at a sufficient geographical extension and within the shortest time possible, as is done in reporting of air temperatures on land to the meteorological centres. It is a question of devising a rationalized technique for speedy sampling of the data and bringing them to the forecaster.

CORRELATION BETWEEN COMPOSITION, STRUCTURE, SHAPE AND FUNCTION OF A SALIVARY MUCOPROTEIN

By Dr. ALFRED GOTTSCHALK
Department of Microbiology, John Curtin School of Medical Research, Australian National University, Canberra

MUCOPROTEINS may be defined as conjugated proteins having hexosamine containing oligosaccharides as multiple prosthetic groups. For bovine submaxillary gland mucoprotein, a representative of this class, Hammarsten[1] established in 1888 the presence of a firm chemical linkage between carbohydrate and protein, and he also recognized the strongly acidic character of the compound. In 1901, F. Muller[2] isolated crystalline D-glucosamine hydrochloride from bovine submaxillary gland mucoprotein and demonstrated the presence of acetyl groups in this mucoprotein. During the next fifty years little attention was paid to mucoproteins and scarcely any notice was taken of the important discovery by Blix[3] of a new, though unidentified acidic carbohydrate in bovine submaxillary gland mucoprotein. The situation changed dramatically when Burnet[4] and co-workers showed: (1) that many glandular mucins of human and animal origin, among them the submaxillary gland mucins of ruminants, inhibited hæmagglutination by heat-inactivated influenza virus, (2) that the active principle of the mucin was a mucoprotein and (3) that living influenza virus and an exo-enzyme of *Vibrio cholerae* (*RDE*) destroyed this inhibitory capacity.

The elucidation of the chemical reaction underlying the enzymic inactivation of the inhibitory mucoproteins was initiated when Gottschalk[5] and co-workers isolated a dialysable compound of low molecular weight from the digest of purified inhibitory mucoproteins and purified influenza virus and *RDE*, respectively. The chemical properties of the 'split product' closely resembled those of the acid isolated by Blix[5] from bovine submaxillary gland mucoprotein and termed in 1952 'sialic acid'[6]. By treating bovine submaxillary gland mucoprotein with 5 per cent methanolic hydrochloric acid, Klenk *et al.*[7] obtained the same methoxyneuraminic acid which Klenk had previously prepared from certain brain mucolipids by a similar procedure. Furthermore they isolated from bovine submaxillary gland mucoprotein N-acetylneuraminic acid and on repeating Gottschalk's work identified the crystalline split product as N-acetylneuraminic acid[7].

Concerning the structure of the new sugar acids, Gottschalk[8] proposed in 1955 on the available data a comprehensive scheme with neuraminic acid as the parent structure common to sialic acid, N-acetylneuraminic acid and methoxyneuraminic acid. Neuraminic acid was visualized as an aldolcondensation product of hexosamine and pyruvic acid, N-acetylneuraminic acid as N-acetylated neuraminic acid, sialic acid as N,O-diacetylated neuraminic acid and methoxyneuraminic acid as the methylglycoside of neuraminic acid. By the fusion of pyruvic acid with hexosamine a keto-, deoxy-, hydroxyl- and amino-group become α-, β-, γ- and δ-positioned respectively to the carboxyl group, an alignment favouring cyclization to a pyrrole ring. It was the conversion of the split product to pyrrole-2-carboxylic acid[9] under mildest alkaline conditions which rendered possible the allocation in space of the functional groups, elaborated previously by Blix *et al.*[10] and Klenk *et al.*[7]. The correctness of the scheme was proved by alkaline degradation of N-acetylneuraminic acid to N-acetyl D-glucosamine and pyruvic acid[11] and by the chemical synthesis[12] of N-acetylneuraminic acid from N-acetyl D-glucosamine and oxaloacetate at *p*H 11·0 and 20°. Recently, Comb and Roseman[13] showed that the N-acetylhexosamine fragment of N-acetylneuraminic acid has the steric configuration of N-acetyl D-mannosamine, the ease of the epimerization reaction N-acetyl D-glucosamine $\rightleftharpoons$ N-acetyl D-mannosamine accounting for the synthesis of natural N-acetylneuraminic acid from N-acetyl D-glucosamine and oxaloacetate.

The main sugar components of the homogeneous submaxillary gland mucroproteins are N-acetylgalactosamine and sialic acid (in the new nomenclature[14] the generic name of all N- and O- substituted neuraminic acids). Bovine submaxillary mucoprotein contains equimolecular amounts of sialic acid (22·4 per cent expressed as N-acetylneuraminic acid) and N-acetylgalactosamine besides small quantities of other sugars. In ovine submaxillary gland mucoprotein the total carbohydrate (42 per cent) consists practically only of N-acetylneuraminic acid and N-acetylgalactosamine in the molecular ratio 1 : 1.

In the elucidation of the structure of the carbohydrate group of the submaxillary gland mucoproteins the *Vibrio cholerae* enzyme *RDE* proved to be a valuable tool. The liberation of 70 per cent of the total sialic acid, and of sialic acid only, from bovine submaxillary gland mucoprotein by *RDE* suggested a terminal position of the acid; the reducing power of the sialic acid released from the non-reducing bovine submaxillary gland mucoprotein indicated a glycosidic (ketosidic) linkage of the terminal sialic acid to its partner, thus allowing classification of the enzyme as a glycosidase. The further qualification of *RDE* as an α-O-glycosidase was derived from *RDE* action on sialyl-lactose. The enzyme was named 'neuraminidase'[15].

The prosthetic group of ovine submaxillary gland mucoprotein was readily released by mild alkali treatment. On heating an ovine submaxillary gland mucoprotein solution, adjusted to *p*H 11·5 with barium hydroxide, at 80° for 15 min., 22 per cent of the prosthetic groups were released, and this treatment could be repeated several times yielding further quantities of prosthetic groups. The prosthetic group was identified as α-D-N-acetylneuraminyl (2 → 6) N-acetylgalactosamine by elementary analysis, cleavage into its components by neuraminidase, consumption of 4 moles IO_4^-/mole and by conversion to characteristic derivatives[16].

The prosthetic groups are joined through their reducing ends to the free carboxyl groups of glutamic and aspartic acid residues by a glycosidic ester linkage. This was first indicated by an appreciable drop in *p*H concomitant with the release of prosthetic groups when an ovine submaxillary gland mucoprotein solution with an initial *p*H of 10·5 was heated at 80°. Quantitative determination of the number of prosthetic groups released and of the number of carboxyl groups unmasked were in fair agreement. The presence of a glycosidic ester linkage to aspartyl and glutamyl respectively was conclusively proved by the reduction of one of the carboxyl groups of the dicarboxylic acids when ovine submaxillary gland mucoprotein, after pretreatment first with trypsin and then with phenyl-*iso*thiocyanate, was dissolved in anhydrous tetrahydrofuran and acted upon with lithium boron hydride. This reagent is known to effect a reductive cleavage of ester linkages without appreciable action on amide or peptide bonds[17]. The recovery of total dicarboxylic acids of ovine submaxillary gland mucoprotein after such treatment was only 12 per cent of the normal value (10·7 gm. dicarboxylic acids expressed as glutamic acids), indicating esterification of one of the carboxyl groups of the missing 88 per cent dicarboxylic acids. Again the reductive cleavage was accompanied by the release of prosthetic groups. The extent of reductive cleavage of ovine submaxillary gland mucoprotein is limited by its rather low solubility in tetrahydrofuran, even after fragmentation by trypsin and blocking of the N-terminals by phenyl-*iso*thiocyanate to suppress ionization. The true extent of esterification is indicated by the finding that 84 per cent of the prosthetic groups are removed by heating ovine submaxillary gland mucoprotein at *p*H 11·5 and 80° for 4 hr.; this figure cannot be increased by more severe alkaline conditions. About 16 per cent of the prosthetic groups are linked in an alkali-stable O-glycosidic linkage, probably to serine and/or threonine[18].

The quantitative amino-acid analysis revealed a nearly complete complement of amino-acids; however, the content of aromatic and sulphur-containing amino-acids was low and that of glycine, proline and β-hydroxy-amino-acids high[19].

The susceptibility of ovine submaxillary gland mucoprotein to trypsin action is sterically hindered by the prosthetic groups which are bulky substituents at the side chains of frequently occurring amino-acids (Fig. 1). One out of 6·4 amino-acid residues carries a prosthetic group and one out of 16 amino-acid residues is a lysyl or arginyl residue, that is, 2·5 prosthetic groups/trypsin-susceptible bond. Removal by neuraminidase of the terminal

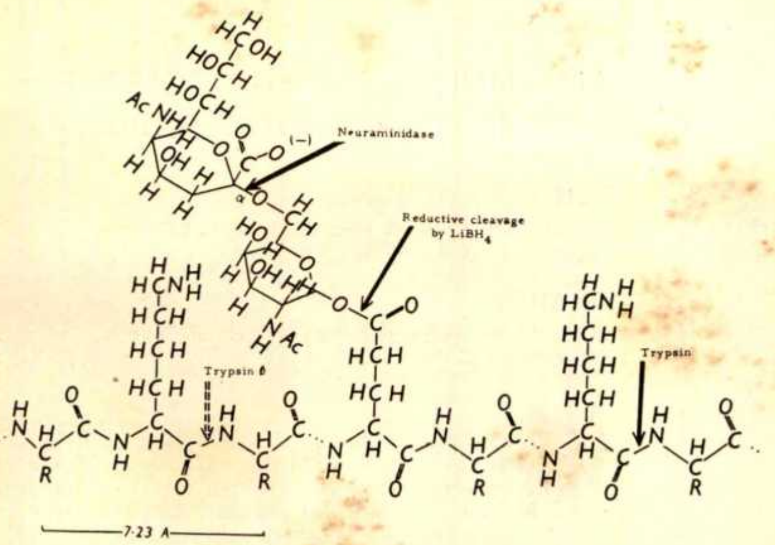

Fig. 1. Diagrammatic segment of ovine submaxillary gland mucoprotein showing: (1) the neuraminidase-susceptible α-ketosidic linkage; (2) the lithium boron hydride-susceptible glycosidic-ester linkage between prosthetic group and the carboxyl of a dicarboxylic acid (here the γ-carboxyl of glutamyl); (3) trypsin-susceptible bonds at the carboxyl of diamino-acids (here lysyl), one accessible to the enzyme, the other sterically hindered by the prosthetic group

N-acetylneuraminic acid units increased by 45 per cent the number of peptide bonds split by trypsin[20].

In the course of these experiments the observation was made that release of N-acetylneuraminic acid by crystalline neuraminidase at pH 6·0 decreased markedly the viscosity of ovine submaxillary gland mucoprotein. Quantitative measurements showed that the reduced viscosity of ovine submaxillary gland mucoprotein at pH 6·1 decreased from 3·13 to 1·33 on treatment with crystalline neuraminidase (free of proteinases). Since N-acetylneuraminic acid like pyruvic acid is a strong acid (pKa = 2·6), this result suggested a dependence of the shape of the molecule on the strongly negative charge of the prosthetic group. To test this suggestion the viscosity of ovine submaxillary gland mucoprotein was measured over a pH range of 7·8–1·8 under comparable conditions of ionic strength. There was little change between pH 7·8 and 4·3 (isoelectric point of ovine submaxillary gland mucoprotein = 4·7); however, the reduced viscosity dropped from 3·50 to 2·50 between pH 4·3 and 1·8, that is, in the pH range of decreasing ionization of N-acetylneuraminic acid. This decrease in viscosity was completely reversible on readjustment of the pH. These results would indicate that the strongly negative charge of the carboxyl groups of N-acetylneuraminic acid is responsible for the extended shape of the mucoprotein. On enzymic removal of N-acetylneuraminic acid at pH 6·0 or on suppression of its ionization the molecule assumes a more compact shape losing thereby its viscous character[21]. Prof. Linus Pauling has suggested to me as a possible structure of ovine submaxillary gland mucoprotein that the protein consists of α-helix segments loosely joined by proline residues. The prosthetic groups would then form a secondary helix around the protein core. It has been shown on models that the average spacing of 6·4 residues offers many possibilities for the formation of hydrogen bonds, in the direction of the helix axis, between adjacent sugar rings. The co-operative effect of the H-bonds and the electrostatic repulsion of the charged carboxyl groups of N-acetylneuraminic acid could preserve a rod-like structure despite the potential flexibility of ovine submaxillary gland mucoprotein at the sites of the proline residues.

In ruminants the submaxillary glands are the main mucus-secreting salivary glands; because of its high mucoprotein content the secretion is very viscous. This secretion together with that of the parotid gland (serous gland) and that of the much smaller sublingual glands (mixed glands) form the saliva. One of the main functions of saliva is to cover the foodstuffs with a lubricant layer of mucus, assisting swallowing and protecting teeth and the lining cells of the mucosa against injury. Of all the substances synthesized by the organism mucoproteins, because of their high viscosity, are especially suited for the functions of lubrication and protection. It seems to be of interest that by such a rather simple expedient as the attachment of strongly negatively charged, multiple disaccharides to the side-chains of the protein core a high degree of viscosity is imparted to the molecule. The wide distribution of neuraminic acid among the viscous epithelial secretions of the respiratory, intestinal and uro-genital tracts may well reflect one, at least, of the physiological functions of this acid. If this concept proves to be true, Nature was wise to incorporate into neuraminic acid the strongest stable organic acid produced in the metabolism of the animal cell.

I am indebted to Dr. G. L. Ada, of the Walter and Eliza Hall Institute, Melbourne, for a generous supply of crystalline neuraminidase.

This work was supported by a personal grant from the National Health and Medical Research Council of Australia.

ULTRA-STRUCTURE OF HUMAN AMNION AND ITS POSSIBLE RELATION TO THE CIRCULATION OF AMNIOTIC FLUID

By Dr. GORDON L. BOURNE
Department of Obstetrics and Gynaecology, St. Bartholomew's Hospital, London, E.C.1
AND
Dr. DENNIS LACY
Department of Zoology and Comparative Anatomy, St. Bartholomew's Hospital Medical College, University of London, E.C.1

THERE is no doubt that some circulation of amniotic fluid occurs between the human fœtus and mother. According to Plentl[1], from work carried out by the use of deuterium, the exchange is about 450 ml. per hr. at term. Plentl has also demonstrated differential rates of transfer of sodium and potassium ions. The turn-over of sodium in the amniotic fluid is believed to occur at about seven times the rate that potassium is replaced. There is no definite information to show either how such large amounts of fluid are conveyed from the fœtus to the mother, or to account for the passage of various ions at different rates. In an attempt to throw further light on these problems we have been investigating the fine structure of the human amnion at term.

An account of the fine structure of the epithelial layer has been published by Lanzavecchia and Morano[2]. This work was carried out at moderate resolution and relates primarily to changes occurring during development.

Amnion was obtained from patients delivered by Cæsarean section at term. The amniotic membrane was dissected from the chorion, and portions of the placental and peripheral amnion were selected for examination.

Small pieces of the membrane were fixed for 2 hr. in osmium tetroxide solution buffered to *p*H 7·3 (ref. 3). The tissue was then rinsed briefly in distilled water, dehydrated in gradually increasing concentrations of ethanol and finally embedded in a 1 : 3 mixture of *n*-methyl and *n*-butyl methacrylate. Sections were cut with a glass knife and mounted on copper grids previously covered with a thin carbon film. The material was examined in a Siemen's Elmiskop 1*a* generally operated at 60 kV. Micrographs were obtained at initial magnifications varying from × 1,000 to × 40,000. The following is a brief account of the main results so far obtained.

Epithelial Layer. This consisted of a single layer of cells the height of which varied from about 1μ to 25μ. At moderate magnification (Fig. 1) the cells appeared to be covered by a single membrane which, on the surface next to the amniotic fluid, was evaginated to form many short processes or microvilli. Along the lateral aspect, the two membranes of adjacent cells delimited a series of irregularly shaped vacuoles (Fig. 1). Some of these vacuoles simply appeared to extend into adjacent ones ; others were connected by fine channels (about 170 Å. internal diameter) formed by the close apposition of the two cell membranes. While the majority of these vacuoles were located in the regions between adjacent cells (that is, were hollowed out in the sides of the cells) a few were seen lying deeper in the cytoplasm. Projecting into some of the vacuoles were a variable number of microvilli, generally less per unit area than seen on the upper surface of the cells. In the basal region the cell membrane was irregular in outline and delimited irregularly shaped vacuoles of various sizes. The appearance of this region, therefore, was similar to that seen along the sides of the cells (Fig. 2). Some micrographs showed that the cell membrane in the basal region was thickened at intervals.

The vacuoles in the lower parts of the cells were generally filled with a substance of moderate density

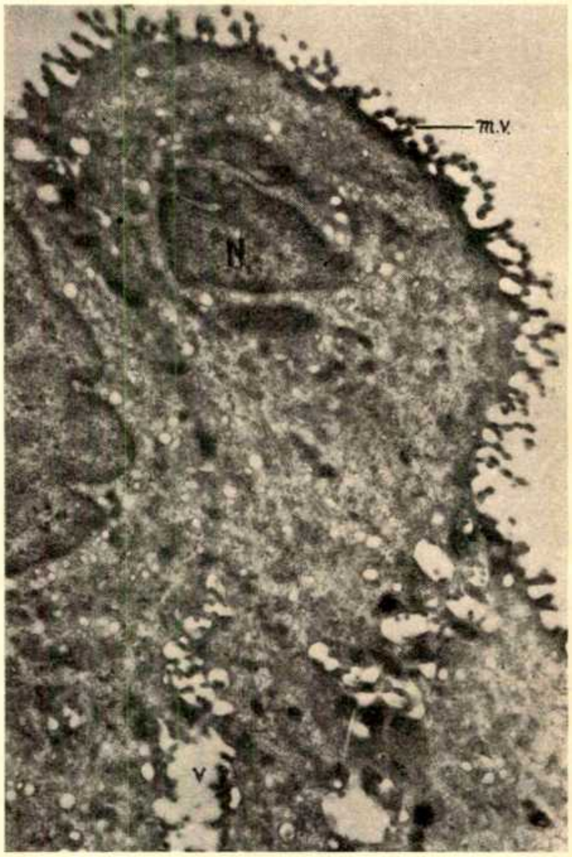

Fig. 1. Micrograph showing the general appearance of the upper part of amniotic epithelial cells. *m.v.*, microvilli ; *N*, nucleus ; *v*, system of intercellular vacuoles. (×10,000)

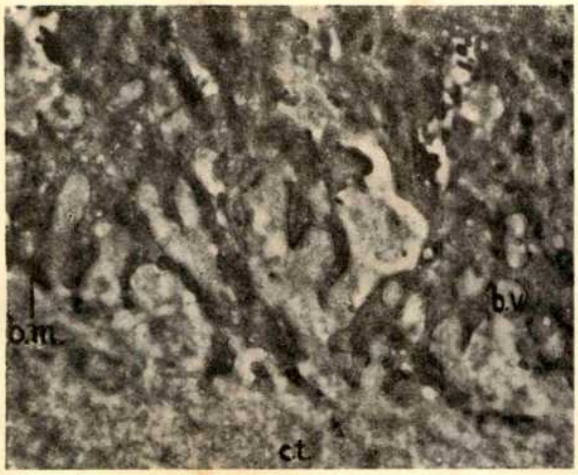

Fig. 2. Micrograph showing the general appearance of part of the basal region of an amniotic epithelial cell. *b.m.*, basement membrane; *b.v.*, basal vacuole; *c.t.*, connective tissue. (×10,000)

which was continuous with, and similar in appearance to, the material forming the basement membrane (Fig. 2). In a few micrographs we observed a similar substance in vacuoles in the upper parts of the cells which communicated with the amniotic fluid. In the majority of our micrographs, however, vacuoles in the upper parts of the cells lacked demonstrable contents.

The cytoplasm of the epithelial cells appeared very dense and granular (Fig. 1). Mitochondria were extremely scarce and when seen were usually in the form of small spheroidal bodies about 0·3μ in diameter. A Golgi apparatus has so far not been observed; if present it was presumably small and inconspicuous. In some cells we observed about two or three (per section) dense bodies each about 1μ in diameter. The nucleus was a large, dense object located close to the upper surface. It was irregular in outline and sometimes fenestrated (Fig. 1).

Various parts of the cells were examined at high magnification and resolution. This revealed that the microvilli were bordered by two closely applied membranes, each about 30 Å. thick. Within the microvilli were many fine rods which, due to the presence of a 'clear' medulla and dense cortex, were canal-like in appearance. The external and internal diameters of these canal-like elements varied; the maximum diameters recorded were 150 Å. (external) and 70 Å. (internal). When seen in cross-section these elements simply appeared to be placed closely together. Rarely, however, elements of similar composition were seen which exhibited the 9 + 2 arrangement found in cilia and flagella[4]. This suggests that occasional cilia existed alongside the microvilli. However, the possibility cannot be ruled out that the 9 + 2 pattern may occur in some microvilli, perhaps during some stage in their development. The canal-like elements penetrated into the cytoplasm to a depth ranging from about 0·25μ to 0·5μ. Due mainly to this there appeared to be a thin layer of particularly dense cytoplasm immediately beneath the microvilli in cells examined at lower magnification (Fig. 1).

When studied at high resolution and magnification, comparatively large areas of the cytoplasm were seen to contain numerous paired parallel lines and circular elements (Fig. 3). These observations are interpreted as showing the presence of membranes arranged mainly in the form of fine canals with some occurring as parallel sheets. The membranes were each about 60 Å. thick, the distance between them (canal lumen) was about 100 Å. Examination of representative parts of the cell surface, where it bordered the lateral and basal system of vacuoles referred to above, revealed many circular apertures (about 75–100 Å. internal diameter) which communicated with the intracellular channels and canals. The evidence suggests, therefore, that amniotic epithelial cells contain an extensive system of canals and channels which communicate directly with the extracellular 'space'. Further details of this system, such as its relationship with the upper surface of the cell and microvilli, are now being studied.

Basement Membrane. This consisted of a thin layer, usually about 0·1μ thick, of a moderately dense substance which penetrated into the vacuolar-like indentations of the cell membrane. At high resolution it was seen to consist of fibrils (each about 200 Å. in diameter) embedded in a material of closely matching density.

Connective Tissue Layer. This relatively deep layer (0·05 mm.–0·5 mm. thick) consisted mainly of fibrils, each about 300 Å. thick and exhibiting faint transverse striations with a periodicity of about 600 Å. The fibrils were branched, the angle of branching usually being about 90°. They were arranged in bundles (not bounded by a membrane) lying in various planes (Fig. 4). Thus in any region a great number of parallel fibrils lay next to a comparable number of similar elements sectioned transversely or obliquely. Such an arrangement accounts for the appearance of a network of fibres in light microscopi-

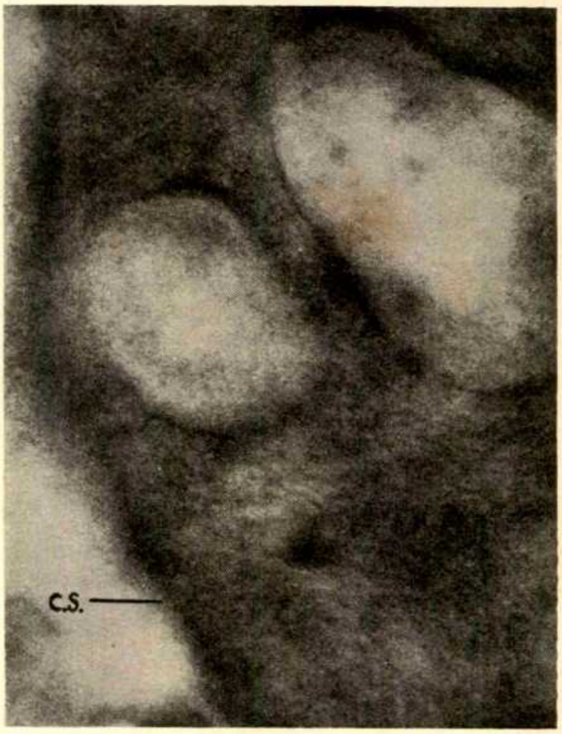

Fig. 3. Micrograph of the numerous membranes found in various regions of the cytoplasm of amniotic epithelial cells. The membranes are believed to be arranged mainly in the form of canals with some occurring as parallel sheets. Along the cell surface (*c.s.*) are many small circles suggestive of pores. (×100,000)

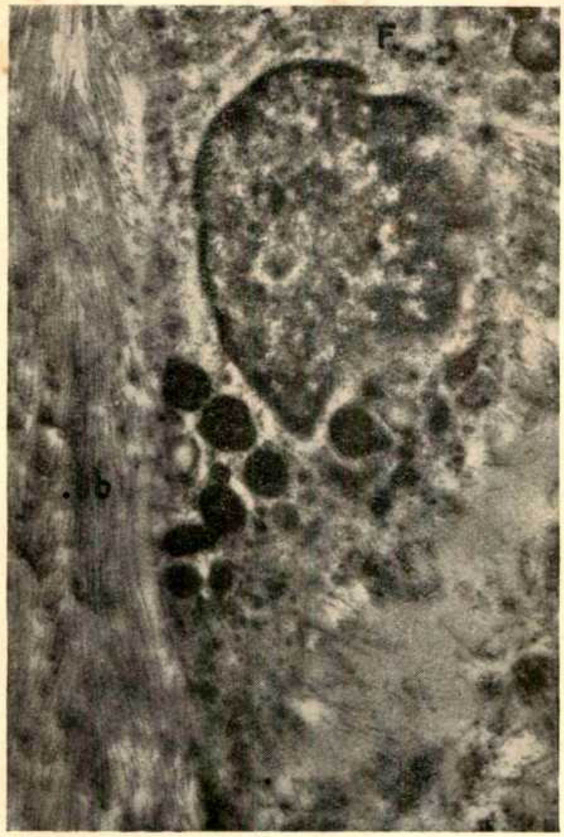

Fig. 4. Micrograph of part of the connective tissue layer showing a fibroblast (*F*) and bundles of fibrils (*b*). Along the lower right-hand side of the cell connective tissue fibrils can be seen partly embedded in cytoplasm. (×9,000)

cal preparations[5]. The morphological evidence, therefore, suggests that the fibrils were reticular fibrils. Typically, in the deeper parts of this layer the fibres had a wavy appearance ; this was probably due to some contraction.

Cells were comparatively scarce and were located in an intermediate zone and in the deeper parts of the layer (fibroblast and spongy layers described by Bourne[5]). These cells were of two kinds : fibroblasts and macrophages. As far as could be determined from individual sections, the fibroblasts in the intermediate zone formed a diffuse network. Parts of the cell surface appeared not to be covered by a membrane. Where this occurred were many connective tissue fibrils projecting from the cell cytoplasm into the extracellular 'space' (Fig. 4). There seemed little doubt that the fibroblasts were actively synthesizing new fibres. The fine structure of these cells varied, either because the cells were of different ages or in different physiological states. Most of them, however, contained an irregularly shaped, dense nucleus (sometimes elongated), a moderately well-developed endoplasmic reticulum (lamelliform and tubular in appearance), mitochondria, Golgi apparatus, groups of fine filaments and several small dense spheroidal bodies. The last-named were possibly glycogen granules[6]. Also present in most cells was a single large mass of material which almost totally occupied the region of the cell in which it was located. This material was bordered by membranes of the endoplasmic reticulum. When examined at high resolution, it was seen to consist of an almost 'clear' matrix within which was a network of greater density. In some cells the network consisted of fibrils (each about 300 Å. in diameter) embedded in a homogeneous ground substance. In other cells the fibrils were scarce or absent and within the ground substance were many small vesicles (each about 500 Å. in diameter). These observations seem to show quite definitely that some connective tissue fibrils were being formed intracellularly.

In the deeper part of the connective tissue layer were elongated cells. The ends of these cells were closely applied and this, together with the fact that the cells followed the wavy course of the connective tissue fibres, made them appear to be articulated. The general appearance of these cells was different from that shown by the cells in the intermediate zone. It seems likely, however, that they were fibroblasts.

The only other cells observed were macrophages. These were very scarce and scattered throughout the connective tissue layer. Within these cells were inclusions which, from evidence obtained by the use of Perl's[7] test for iron (on sections examined under the light microscope), probably contained hæmosiderin.

So far as can be determined on a purely morphological basis, it seems likely that some of the amniotic fluid which passes from the fœtus to the mother, and the accompanying differential rate of turn-over of various ions, may be brought about by the amnion. As a working hypothesis it may be conjectured that the fluid enters the amnion via (*a*) the opening between adjacent cells, where it passes into the lateral system of vacuoles and (*b*) the upper surface, the area of which is greatly increased by the presence of microvilli. Within the cells the fluid presumably enters the complex system of fine canals and channels. The fine canals and channels communicate with the lateral and basal vacuoles and hence with the extracellular space ; this results in an enormous increase in surface area. Within the vacuoles there is presumably some mixing of any solution which may have entered via the two principal pathways. Assuming that some ions travel more readily along one route than the other, then this could offer an explanation (although much over-simplified) of the differential rate of turnover of different ions. Having passed through the epithelium the fluid must permeate the connective tissue layer. Since this layer consists mainly of a network of fibres there is no objection to this on morphological grounds.

Experiments are being carried out to examine the validity of the above hypothesis. This part of our work is at an early stage. However, 30 min. after the injection of colloidal gold in the amniotic fluid a few small particles of gold have been observed in the connective tissue layer, either scattered along the length of some of the fibrils or around small processes of the fibroblasts.

The above work was undertaken during the tenure of a Lawrence Research Scholarship of St. Bartholomew's Hospital held by one of us (G. L. B.).

GEOPHYSICS

Regular Micropulsations of the Earth's Field at the Equator

THE diurnal variation of occurrence of regular pulsations, *pc*, of the Earth's magnetic field has been studied by many workers and it has been found, in all the cases reported, that the phenomenon is predominantly a day-time one. Typical of the results of magnetic measurements are those obtained in Germany by Angenheister[1], for periods of 30–60 sec., which have a maximum frequency of occurrence at 10–12 hr. L.M.T. The measurements of Earth currents, obtained in the U.S.S.R. by Mme. Troitskaya[2], are representative of that experimental approach and they show a maximum frequency of occurrence around 11–13 hr. L.M.T. Most of the results reported have been confined to mid-latitude stations.

At the symposium on "Rapid Variations of the Earth's Field" held at Utrecht in September 1959, I gave a brief report of an analysis of records of Earth currents obtained at Legon, Ghana (lat. 5° 38′, N., long. 0° 11′ W.). This analysis indicated that, at this station, regular pulsations of Earth currents occur during the night as well as during the day and, in fact, that the maximum frequency of occurrence for the whole day is at approximately 18–20 hr. G.M.T. The diurnal variation of frequency of occurrence of regular pulsations, *pc*, for all days, is shown in Fig. 1*a*, which was the result of an analysis of records of Earth currents obtained between October 1957 and December 1958. More recently, analysis of magnetic records obtained from an induction magnetometer, recording d*H*/d*t* at the same station, has shown a similar night-time occurrence of regular pulsations, in addition to the day-time occurrence normally expected. The results of this analysis, which was made for the months of May, June and July 1958, are given in Fig. 1*b*, together with the results obtained from records of Earth currents for the same 3 months. Both graphs show three maxima, occurring at 6 hr., 12 hr. and 20 hr., and in each case the night-time maximum is the greatest. In fact, there is approximately a 50 per cent chance that regular pulsations will occur between 19 and 21 hr. It is probable that the difference in level of frequencies of occurrence in the two cases is due partly to the different sensitivities of the telluric and magnetic recording systems, and partly to the fact that the Earth-current records and magnetic records were examined by the same observer at different times. A separate study has also been made of the degree of subjectivity in the examination of records for the occurrence of these regular pulsations, by having three observers independently analyse the same records. In all cases, the results gave rise to graphs of very similar form to that in Fig. 1*a*, but the mean value of frequency of occurrence differed from one observer to another, a factor which

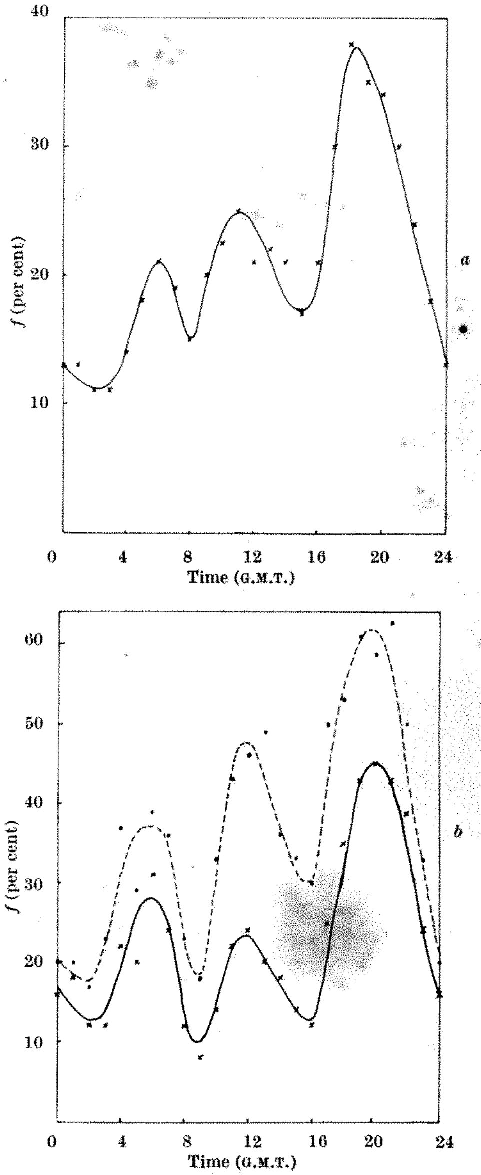

Fig. 1. Diurnal variation of frequency of occurrence, *f*, of regular pulsations at Legon. (*a*) Telluric pulsations for October 1957–December 1958; (*b*) telluric and magnetic pulsations for May–July 1958. Telluric, ———; magnetic, - - - - -

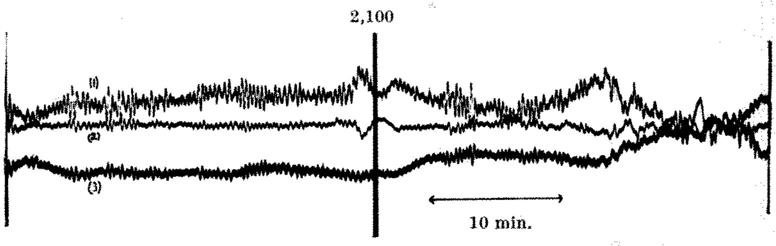

Fig. 2. Example of night pulsations at Legon on both telluric and magnetic traces: May 27, 1958, 2030–2130 hr. (1) E.-W. telluric current; (2) d*H*/d*t*; (3) N.-S. telluric current

was not of primary importance in the present study.

This analysis of both telluric and magnetic records and the independent examination of records by three observers confirms the existence of regular pulsations, *pc*, during night-time as well as during the day, in the equatorial region. An example of these night-time pulsations, on both Earth-current and magnetic traces, is given in Fig. 2.

The Earth-current results have been further analysed to give the diurnal variation of occurrence of regular pulsations for quiet days only and for different seasons of the year and the results compared with a similar study of results from Tamanrasett (long. 22° 48′ N., lat. 5° 31′ E.). Two of the main deductions which may be made from this investigation, which will be reported more fully elsewhere, are : (1) that the frequency of occurrence of regular pulsations at night is greater at Legon than at Tamanrasset ; and (2) that, for quiet days, in the interval 0–14 hr., the frequency of occurrence of regular pulsations at Legon is almost the same as that at Tamanrasset. In both cases there is good agreement in this time interval, with the occurrence of the phenomenon at other stations.

Structure of the Upper Mantle as derived from the Travel Times of Seismic *P* and *S* Waves

IN a recent investigation[1] I found the travel times of the seismic *P* waves (longitudinal waves) up to an epicentral distance of about 22° to conform with a structure below the Mohorovičić discontinuity that consists of an upper layer extending to a depth of about 220 km. in which the velocity is about 8·1 km./sec., increasing slightly with depth, and a lower layer in which there is a considerable increase of velocity with depth ; at the boundary of the two layers there is an abrupt increase of velocity to about 8·4 km./sec. A discontinuous increase of velocity has to be assumed because the amplitudes of the waves refracted in the lower layer, observable as first arrivals from an epicentral distance of about 15°, increase gradually with epicentral distance, and at the lower end of their time-distance curve there is no focal point at which the amplitudes are very large.

The transverse *S* waves in the same distance-range are less well observed in most regions. In north-eastern America, however, good observations are obtained, and it is found that the S_d waves travelling in the uppermost part of the mantle have a velocity of about 6·5 km./sec., increasing slightly with depth[2]. They are not observed beyond about 14° epicentral distance and the *S* phases observed at greater distances are delayed. This is explainable on the assumption that there is a low-velocity layer extending from a depth of about 150 km. to the discontinuity surface at 220 km. depth. At this surface there is, as for *P*, a sudden increase of velocity and of velocity gradient.

In Europe the S_d phase of shallow shocks is so poorly observed that it was not found possible to construct a time-curve for it directly from observations. The Jeffreys–Bullen time-curve was derived from the S_d travel-times for deep-focus shocks. In a few shallow earthquakes, however, I now find the S_d phase well enough observed to be able to show that the travel times are very nearly the same as in north-eastern America.

In shallow shocks the observations of *S* at distances up to about 20° are complicated by the fact that two phases, a first small phase and a second larger one, appear at intervals ranging from a few seconds at the greater distances to 20 sec. or more at the smaller distances, and one or the other of the two phases may seem to be *S*. The first phase, which may be small enough to escape detection or may be missing, is the S_d phase. The travel times of the later phases scatter a great deal and it was not previously found possible to indicate a structure that would account for them. It appears now, however, that a structure similar to the one adopted for north-eastern America will give rise to phases having travel-times in fair agreement with those of the late *S* phases observed. From an epicentral distance of about 9° onwards they are explainable as reflexions on, and refractions in, the layer below 220 km. depth, their delay against S_d being due to the presence of a low-velocity layer. At epicentral distances smaller than 9°, second mode surface waves seem to be responsible for the late phases.

In earthquakes having their foci at intermediate depth late *S* phases also occur. The *S* phases of six Rumanian earthquakes having a common focus at 130 km. depth were examined and found to be in agreement with those calculated on the assumptions here indicated.

The travel-times of *P* were found to be consistent with a structure that had no low-velocity layer, and although it is physically possible for the velocity of *S* to decrease while that of *P* does not, yet it seems more likely that the *P* velocities are somewhat affected in the layer in which the *S* velocities are low. The velocity distribution for *P* waves was therefore altered so as to include a layer of slightly smaller velocity extending from 150 to 220 km. depth, and it was found possible to do this without altering the travel-times appreciably.

Dr. Mark Landisman of the Lamont Geological Observatory has given kind assistance in the present research, calculating travel times on the Columbia University *I.B.M.* 650 calculator.

Adsorption of Helium on Carbons : Influence on Measurement of Density

THE magnitude of the adsorption of helium on solids is of interest not only theoretically, but also because of its relevance to the determination of the density of solids when helium is used as the dilatometric fluid ; in such determinations the adsorption of helium is assumed to be so small as to be negligible. We have found that this assumption is not invariably correct.

In the determination of a gas/solid adsorption isotherm by use of the conventional volumetric

* Difficult to outgas completely ; pumped at 630° K. for 1 week.

adsorption apparatus, the dead-space within the apparatus is assessed by application of the gas laws to the pressure/volume data for a given amount of helium enclosed in the apparatus. Should the adsorption isotherm of helium on the solid be linear—as is very probable—the adsorption of helium will remain undetected during the assessment of the dead space of the apparatus ; conversely, the adsorption isotherm of helium on a solid cannot be determined by conventional means. For the measurements reported here, the effect of temperature on adsorption has been employed by measuring the apparent dead-space of a conventional volumetric adsorption apparatus, the temperature of the bulb containing the adsorbent being changed after each determination. The occurrence of appreciable adsorption is shown by an increase in the apparent dead-space as the temperature of the adsorbent is lowered. Our investigations have embraced various forms of carbon as the adsorbent, and the temperature of the adsorbent has been varied over the range 77–580° K. All adsorbents (with one exception) were out-gassed at 630° K. for at least 24 hr. before adsorption measurements were made, and reproducible results were obtained with both ascending and descending temperatures.

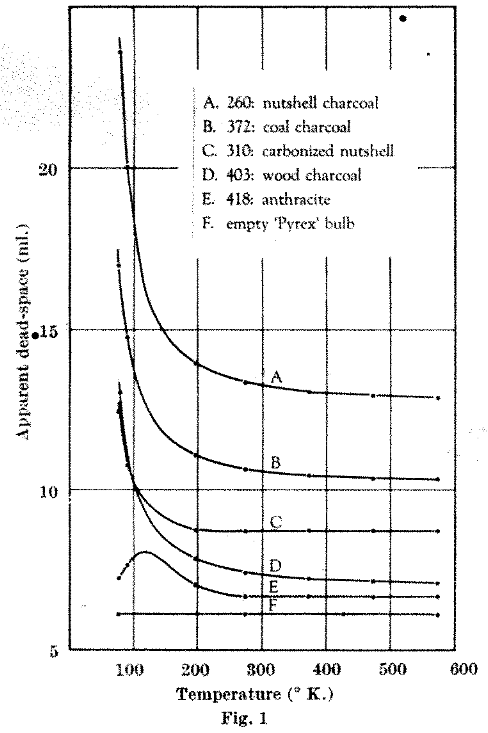

Fig. 1

Several typical sets of results are shown in Fig. 1, which is a graph of the apparent dead-space as a function of temperature. In all cases the value of the apparent dead-space became constant, or nearly so, at the higher temperatures, and the value observed at 580° K. has been taken as the true dead-space for the purpose of calculating minimum values for the adsorption of helium at lower temperatures. With all the forms of carbon examined (see Table 1) adsorption at 77° and 90° K. was readily observed and measured. At 273° K. adsorption was small and varied in extent with the type of carbon. Since our present concern lies with the influence of this adsorption on density measurements, the adsorption at 298° K. (a common temperature of operation in such determinations) is recorded in Table 1 as the slope of the linear adsorption isotherm (ml. standard temperature and pressure per cm. mercury pressure per gm. adsorbent).

On the basis of these results two groups of carbon may be differentiated.

(*A*) Carbons which absorb appreciable quantities of helium at room temperature. All the activated carbons come into this group. Results so far indicate adsorption proportional to surface area ; if the latter is assessed from determinations of the heat of wetting in methanol, an approximate guide to the extent of adsorption at 298° K. on a given carbon is given by the proportionality constant $2 \cdot 1 \times 10^{-5}$ ml. helium per cm. mercury per cal. Adsorption at room temperature was also observed on a finely divided graphite (nitrogen, Brunauer–Emmett–Teller area, 625 m.^{2}/gm.).

(*B*) Carbons for which no adsorption at 298° K. has been detected. The following carbons are found in this group : an anthracite ($C = 93 \cdot 8$ per cent dry ash-free) ; a free-burning bituminous coal ($C = 82 \cdot 4$ per cent dry ash-free) (because of the continued evolution of gases with increasing temperature, the coal was outgassed at 430° K., and the dead-space measured at 398° K. was taken as the true dead-space) ; carbonized coconut shell (unactivated) ; a carbon black (particle size 190 Å., from electron micrographs).

Both the anthracite and the coal gave evidence of restricted adsorption at 77° K. (ref. 1). For group *A* carbons the effect of these small adsorptions on the measured density is most marked. The densities of the carbons as measured by the method of helium displacement at 298° K. are given in Table 1; in the last column are the densities corrected for the observed adsorption of helium.

The reason for the difference in behaviour of the two groups of carbons is not immediately apparent. Both groups contain carbons of comparable specific area; no correlation with ash content is discernible. It appears possible that very small capillaries accessible only to helium may be present in group *A* carbons; some support is given to this explanation by density measurements using methanol as the dilatometric fluid, though this interpretation is dependent on the value assigned by Franklin[2] to the correction for adsorption of methanol.

A Self-supporting Metal Fresnel Zone-plate to focus Extreme Ultra-violet and Soft X-Rays

IN the wave-length region between 10 Å. and 1000 Å., ordinary lenses and mirrors fail as image-forming devices because the transmissivity and reflectivity of materials are very low. In this region diffraction offers a means of bending rays and focusing them.

We have produced a Fresnel zone-plate consisting of 19 metal zones held together by thin radial struts so that the transparent zones are empty. This permits soft X-rays and ultra-violet radiation to pass through and be focused. The device has been tested with visible light and ultra-violet light down to 2537 Å. It behaves as expected in terms of speed and resolution, leading to the belief that it should focus well even at wave-lengths less than 100 Å.

The zone-plate has a central circle of diameter 0·04 cm., an outer circle of diameter 0·26 cm., and is about 10 microns thick. The narrowest gold band has a width of 20 microns. It was made by the Buckbee Mears Company of St. Paul, Minnesota, by techniques that are an outgrowth of the lithographic art.

The zone-plate was better than the optimum pin-hole by a factor of 6 in resolution and 40 in speed. Pictures of fine-mesh screens showed that its resolution compared favourably with that of a simple plano-convex lens of similar aperture and focal length. The lens was about 20 times faster than the zone-plate in visible light, but at 1000 Å. the zone-plate would have been much faster than a lens of any known material. Tests made at 6700, 4358 and 2537 Å. showed that the resolution improved, as would be expected from the Rayleigh criterion, auguring well for resolution at 100 Å.

Means are being considered for integrating the information from a bank of many zone-plates, so as to increase the speed of the system, possibly by some television-type scanning and integrating device.

We may gain some idea of possible future uses of a zone-plate X-ray telescope in an orbiting satellite above the Earth's absorbing atmosphere by considering the results of an experiment at 2537 Å. and extrapolating. At 2537 Å. the angular resolution was close to the theoretical value of $1 \cdot 2 \times 10^{-4}$ radian and held over a field of at least $1 \cdot 75 \times 10^{-2}$ radian, which is 2·0 times the angle subtended by the Sun's disk at the Earth.

A detailed paper on this investigation is being submitted to the *Journal of the Optical Society of America*.

Interpretation of Intensity Distributions in the N_2 Lyman–Birge–Hopfield and CO Fourth Positive Band Systems

IN much of the early spectroscopic literature the photographic density (measured or estimated by eye) of spectral features is reported, in addition to wavelengths, as an aid to identification. In many molecular band systems in the vacuum ultra-violet region (which are becoming of increasing interest in astrophysics and plasma physics and the intensities of which, *in emission*, are relatively difficult to measure) the early data on photographic blackening are still the only experimental information on band intensities available.

Until reliable measurements of intensities have been made, it is therefore worth while to inquire into what quantitative conclusions, if any, may be drawn from the plate blackenings.

A simple method was developed some years ago[1,2] by which a test of quantitative significance is first applied to the blackening data, after which quantitative conclusions may be drawn from analysis of those data which are retained as meaningful. This method has now been applied to blackening data reported for the $N_2(a^1\Pi_g - X^1\Sigma_g^+)$ Lyman–Birge–Hopfield and the $CO(A^1\Pi - X^1\Sigma^+)$ Fourth Positive band systems which are comparable transitions of isoelectronic molecules and lie in the vacuum ultra-violet region between about 1250 Å. and 1850 Å.

It has been shown[1], for molecular band systems, that the plate blackening B_λ is related (*a*) to the emulsion response parameters: contrast γ_λ and inertia $I_{0\lambda}$; (*b*) to the molecular parameters: wavelength $\lambda_{v',''}$, Franck–Condon factor $q_{v'v''}$, electronic transition moment $R_e(r)$, and *r*-centroid $\bar{r}_{v'v''}$; and (*c*) to the population $N_{v'}$ in the vibrational level v' by:

$$B_\lambda = \gamma_\lambda\,[\text{constant} - \log I_{0\lambda} + \log N_{v'} + \log q_{v'v''} - 4 \log \lambda_{v'v''} + 2 \log R_e(\bar{r}_{v'v''})] \quad \cdot \quad (1)$$

The test of quantitative significance is to plot B_λ against $\log q_{v'v''} - 4 \log \lambda_{v'v''}$ for each v'' progression (v' = constant). Meaningful data fall on straight lines of roughly equal slope γ^λ for each progression. Aberrant B_λ values are rejected. The relation between $\log R_e(r)$ and $\bar{r}_{v'v''}$ may then be found by plotting $B_\lambda/\gamma_\lambda + 4 \log \lambda_{v'v''} - \log q_{v'v''}$ against $\bar{r}_{v'v''}$ (or $\lambda_{v'v''}$, as $\bar{r}_{v'v''}$ and $\lambda_{v'v''}$ are monotonically related[3]) for each progression. The segments, one for each progression, will be displaced in relative ordinate by amounts depending upon the influence of $N_{v'}$, from which the distribution of $N_{v'}$ with v' can be found. Objective rescaling of the segments leads to a graph of $2 \log R_e(r)$ + a constant versus $\bar{r}_{v'v''}$ (or $\lambda_{v'v''}$) for the entire band system.

This procedure has been carried through for the blackening B_λ and wave-lengths $\lambda_{v'v''}$ reported by Headrick and Fox[4] for the CO Fourth Positive system and by Birge and Hopfield[5] for the N_2 Lyman–Birge–Hopfield system. Franck–Condon factors were available for each system[6,7] as were r-centroids[3,8]. In the graphs actually made, however, it was sufficient to plot $B_\lambda/\gamma_\lambda + 4 \log \lambda_{v'v''} - \log q_{v'v''}$ versus $\lambda_{v'v''}$. Data were found to be meaningful for 19 bands of six progressions ($v' = 0$–5) for the Lyman–Birge–Hopfield system, and for 11 bands of four progressions ($v' = 0, 1, 3, 4$) of the CO Fourth Positive system. In both cases the graph of $B_\lambda/\gamma_\lambda + 4 \log \lambda_{v'v''} - \log q_{v'v''}$ versus $\lambda_{v'v''}$ was parallel to the $\lambda_{v'v''}$ axis, which is good evidence that $R_e(r)$ must be almost independent of r, and thus constant, for each system.

It may therefore be concluded that for these two bands systems the ($v'v''$) array of relative vibrational transition probability:

$$p_{v'v''} = \bar{R}_e^2(r_{v'v''})q_{v'v''} \tag{2}$$

which, influences, the intensity $I_{v'v''}$ in emission of the $v'v''$ band through:

$$I_{v'v''} \propto N_{v'} p_{v'v''}/\lambda^4{}_{v'v''} \tag{3}$$

is probably, therefore, well represented in each case by the respective Franck–Condon factor $q_{v'v''}$ array.

Millimetre Waves from Mercury Arc Harmonic Generator

THE use of very small mercury arcs for the purpose of harmonic generation from a microwave input at 2·5 Gc./s. has already been described[1]. I wish now to report the preliminary results obtained with a driving frequency of 35 Gc./s.

For operation at this high frequency, the arc was formed between a vertical tungsten wire 'anode' mounted parallel to the electric vector of the microwave field across a Q-band wave-guide of stainless steel, a mercury pool cathode forming the lower surface of the wave-guide. Harmonics generated by the arc were collected by means of a smaller wave-guide protruding perpendicularly through the side wall of the Q-band guide. The whole device was filled with argon gas at 20 atmospheres pressure, mica windows permitting the entry and exit of microwave power. The level of the mercury surface could be varied by tilting, and the length of the arc was thus adjusted to be less than 0·5 mm.

The 35 Gc./s. drive was supplied by a continuous-wave klystron supplying about 1 watt into the discharge, an 8-volt d.c. supply connected across the arc causing a noticeable increase in efficiency of harmonic production. The combined rectified current was about 100 m.amp.

The highest harmonic found so far is the sixth, corresponding to a frequency of 210 Gc./s. and a wave-length of 1·43 mm., the receiver being a Golay infra-red detector. It has not yet been possible to 'match' the arc to the output circuit, so that the power reaching the detector at 210 Gc./s. is quite small (rather less than 10^{-8} watt); but if an efficient coupling can be devised it should be possible to extract up to a hundred times this power from the discharge. The power in the fourth harmonic (2·15 mm. wave-length) is about 15 db. greater than that in the sixth.

The work described here forms part of the research programme of the National Physical Laboratory, and this communication is published by permission of the Director of the Laboratory.

METALLURGY

Crystal Growths and the Corrosion of Iron

THE effect of climate on the corrosion of iron has been the subject of many studies. Hudson[1] and more recently Copson[2] have summarized studies on the rate of corrosion of ingot iron in dry and moist climates and in industrial and marine atmospheres. Ingot iron in the dry atmosphere of Khartoum, Egypt, corroded at a rate of 28 millionths of an inch a year while a specimen in the wet country atmosphere of Llanwrtyd Wells, England, corroded at a rate of 1888 millionths of an inch a year.

Critical laboratory studies by Vernon[3,4] on the effect of humidity on the corrosion of iron led to the generalization known as the "Principle of Critical Humidity". For iron, at 25° C., the rate of corrosion increases rapidly for humidities above 65 per cent. Dry oxidation is assumed to change to a rapid electrochemical attack. Local electrochemical action is assumed to occur between local anode and cathode areas through an invisible adsorbed film of water.

This model of localized electrochemical action is the basis of present-day interpretation of wet corrosion. For pure single-phase metals the sites for local cathodes and anodes have not been identified. Part of the difficulty is that liquid-phase corrosion reactions on iron are complex since hydrated oxides are often formed and the corroding metal may be removed from the reaction site.

Gulbransen and Copan[5] proposed that localized chemical reactivity in corrosion processes could be studied in gas phase reactions at elevated temperatures using more nearly ideal reaction conditions and pure metals. Since localized corrosion processes may be the result of dislocations and other defects which occur on an atomic scale, it is necessary to use high-resolution electron microscope methods.

To show the effect of water vapour on the corrosion of iron, we exposed annealed pure zone-refined iron wires to oxygen, water vapour and several gas mixtures of water vapour and oxygen. The 0·0225 cm. wires were treated in a special reactor system at 450° C. for 48 hr. For these conditions electrochemical action and solution of the corrosion product in a liquid phase are eliminated. The complex

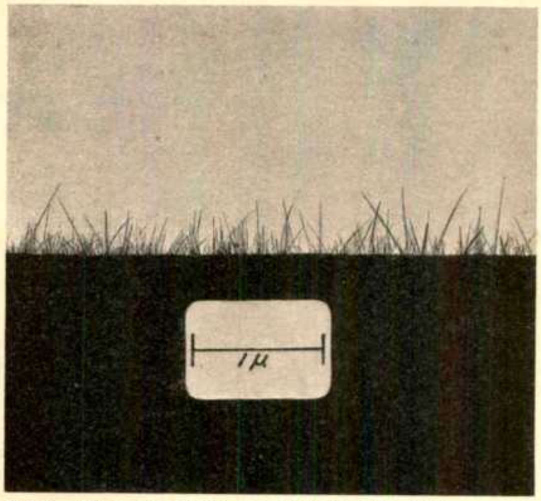

Fig. 1. Effect of moisture on crystal habits of the corrosion products formed on iron after reaction at 450° C. for 48 hr. in dry oxygen

hydrated oxides also are not stable. Electron microscope and electron diffraction studies were made of the edge of the wire specimen after reaction.

Figs. 1 and 2 shows two electron transmission micrographs of the crystal habits of the localized corrosion products. Fig. 1 shows small oxide whiskers were formed when iron was treated with dry oxygen of dew point − 79° C. These whiskers were 150–200 Å. in diameter and grew to an average height of about 8000 Å. Electron diffraction analyses showed the whiskers to be only α-Fe_2O_3. These whiskers were formed in addition to the normal oxide film. Fig. 1 suggests that the nucleation sites on the metal or on the oxide were 150–200 Å. in diameter. Since the diameter was constant along the length of the whisker, we conclude that the length of the nucleation sites remained constant as the whisker grew. The area of the nucleation site appeared to be independent of time or the extent of oxidation.

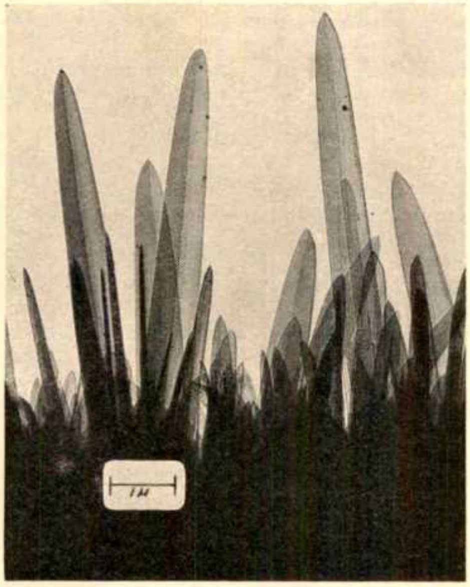

Fig. 2. Effect of moisture on crystal habits of the corrosion products formed on iron after reaction at 450° C. for 48 hr. in 10 per cent water plus 90 per cent oxygen

Fig. 2 shows the crystal habits formed when iron reacts with a 10 per cent water vapour + 90 per cent argon mixture at 450° C. for 48 hr. Many thin blade-shaped platelets were formed. These were 100–200 Å. thick, up to 8000 Å. long, and up to 70,000 Å. high. Electron diffraction analyses showed these platelets to be only α-Fe_2O_3. The surface density was estimated to be about 10^8/cm.^{2}.

The shape of the oxide platelets suggests that the site for reaction enlarges as the reaction proceeds, whereas in the iron–oxygen reaction the site remains of constant area. The constant thickness of the platelets suggests that the width of the nucleating area remains constant. One explanation for the effect of water vapour is that hydrogen ions from the water vapour act to enlarge the area for reaction.

After 48 hr. of reaction the site areas are fifty times the areas observed for the dry oxygen reaction. The total amount of oxide in the form of localized corrosion products for the water vapour reaction is about four hundred times that formed in the dry oxygen reaction.

These experiments made at 450° C. may help to explain the unique effect of water vapour on the corrosion of iron at ambient temperatures. Certain differences of course exist. The corrosion-rate will be slower, hydrated oxides may form instead of α-Fe_2O_3, the corrosion product may dissolve in the liquid phase, and electrochemical action may be present. The important factor which has not been foreseen in earlier studies is the accelerating effect of water vapour itself on localized corrosion in the absence of electrochemical action.

ENGINEERING

Tensile Behaviour of Pyrolytic Graphite at 2,750° C.

ENGINEERING stress–strain curves have been obtained at temperatures of 1,650–2,750° C. for a pyrolytic graphite which had been heated to 2,870° C. Changes in the crystal structure as determined by X-ray diffraction and changes in the microstructure caused by the heating and straining have been observed.

According to the manufacturer (Raytheon Manufacturing Company) the polycrystalline material tested was deposited at 2,100° C. on a substrate of synthetic graphite by decomposition of a methane–hydrogen mixture. The as-deposited material had a density-range of 2·19–2·21 gm./c.c. and, as shown in Fig. 1, had a 'block-like' structure of conical elements called 'growth cones'. From the surface appearance of the specimen blanks it was possible to divide them into four classes according to the size of the visible 'growth cones'. All specimens were heated in argon to 2,870° C., held for 5 min., and cooled to room temperature prior to testing.

The details of the testing method and equipment used have been described previously[1,2]. All specimens

† Fracture occurred at growth cone.

had a gauge section 0·75 in. long by 0·06 in. wide by 0·1 in. thick and were taken from blanks 3 in. long by 0·75 in. wide by 0·1 in. thick with the thickness direction perpendicular to the basal planes. In some cases the as-deposited material was greater than 0·25 in. thick, so that it was possible to obtain specimen blanks 0·1 in. thick from the material deposited during the latter part of the process (Table 1 'Top'), and also from the material deposited during the early part of the process (Table 1, 'Sub'). The stress was applied parallel to the basal planes at a cross-head speed of 1·5 × 10^{-4} in./sec. All elevated temperature tests were made in helium.

Results obtained are given in Table 1. These are in general agreement with preliminary results previously reported[3]. The present specimen configuration permitted measurement of ductility and confirmed the previous indication that at temperatures above 1,650° C. pyrolytic graphite has greater ductility than commercial synthetic graphite.

The microstructure before and after deformation at 2,750° C. is shown in Fig. 1. As seen, a marked change has occurred after tensile deformation in that the 'growth cone' structure has almost disappeared. This is true after 18 per cent as well as after 60 per cent deformation and is similar to the change reported by Pappis[4]. No change in microstructure was observed to be produced by heating at 2,870° C.

Spectrometer tracings (Fig. 2) show the effects of heating and tensile deformation on the three-dimensional graphite ordering. After the as-deposited material was heated to 2,870° C. and after 18 per cent deformation at 2,750° C. there appeared to be partial

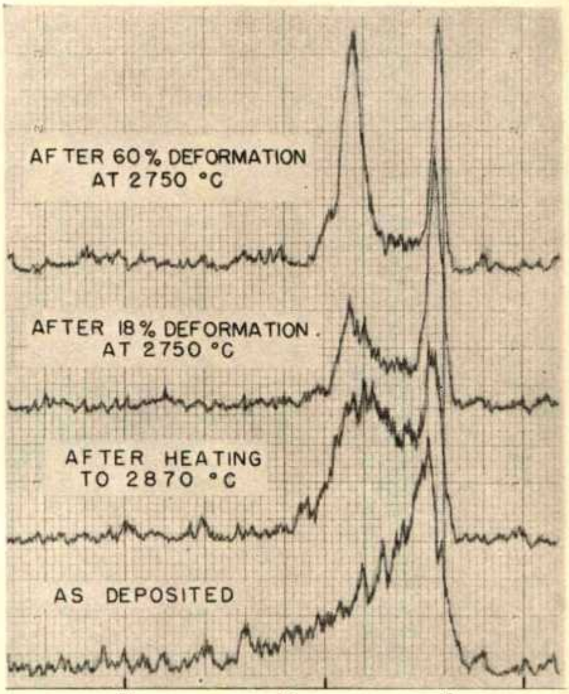

Fig. 2. Development of modulations in the (10) X-ray reflexion of pyrolytic graphite with heating and straining

three-dimensional ordering. After 60 per cent deformation at 2,750° C. there appeared to be complete ordering, as indicated by the complete splitting of the two dimensional (10) reflexion into the crystalline (100) and (101) reflexions.

CRYSTALLOGRAPHY

Effect of a Second Crystalline Modification in Polyethylene on X-Ray Crystallinity Measurements

FROM several investigations it is known that in solid polyethylene which has undergone severe mechanical treatment a second crystalline modification may occur besides the normal rhombic one[1]. In the X-ray diagram the strongest reflexion of this second modification coincides with the maximum in the so-called amorphous band (the broad halo of diffraction emanating from the amorphous regions). In view of the fact that the amorphous band in unbranched polyethylenes appears to be abnormally narrow, Slichter[2] suggests that the second modification also occurs in undeformed polyethylene. In this communication I want to point out that this suggestion may explain certain anomalies in the results of the density and crystallinity measurements described below.

If polyethylene is assumed to consist of an amorphous and a rhombic crystalline phase only, the density d_{tot} is related to the crystalline fraction φ as follows:

$$\frac{1}{d_{\text{tot}}} = \frac{\varphi}{d_{\text{rh}}} + \frac{1-\varphi}{d_{\text{am}}}$$

where d_{rh} and d_{am} are the (rhombic) crystalline and amorphous densities, respectively. Originally, our aim was to find d_{am} values for different specimens from measurements of the quantities d_{tot}, d_{rh} and φ. The measurements were made as follows: (1) d_{tot} was determined at 23° C. by a flotation method. (2) d_{rh} was calculated from the cell dimensions, which were determined from the X-ray diffraction angles of the (200), (020) and (011) reflexions. The polyethylene samples were mixed with sodium chloride which served as a standard. (3) The crystalline fractions were measured by Krimm and Tobolsky's[3] X-ray method. In this method the intensity of coherent scattering from the amorphous fraction is compared with the corresponding intensity from the molten sample. The necessary monochromatization of the X-ray beam was obtained by the double filter technique of Ross[4] as described by M. Kakudo and R. Ullman (private communication).

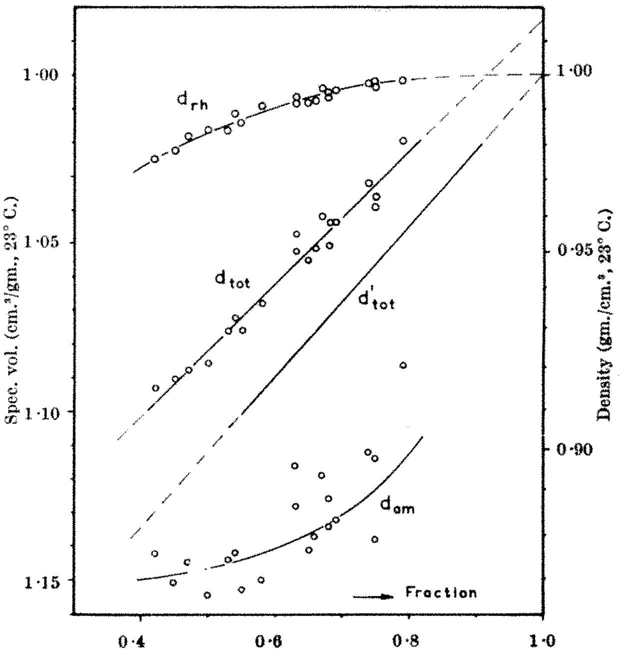

Fig. 1

Altogether five different polyethylene samples were investigated, each being cooled from the melt at four different rates.

In Fig. 1 both the measured values of d_{rh} and d_{tot} and the calculated values of d_{am} are presented as functions of the crystallinity φ. (The curve through the points d_{tot} is based on some twenty more incidental measurements, which are not shown in the figure.)

This graph is not satisfactory for two reasons. First, the calculated values of d_{am} are in the range 0·865–0·92 gm./cm.³, which is much higher than that found by extrapolating the density of molten polyethylene to room temperature (0·83–0·85 gm./cm.³). The maximum density to be expected for amorphous polyethylene can be estimated by calculating the density of a hypothetical phase in which the chain molecules are parallel and close-packed, and can rotate around their chain axes. With the shortest possible distance between the centres of the chains (4·95 Å.), the calculated density is 0·86 gm./cm.³, which is lower than the values shown in Fig. 1.

Secondly, the extrapolated curves for d_{tot} and d_{rh} should intersect at $\varphi = 1$, which they clearly do not.

A possible explanation of these discrepancies is that some systematic error was made in our measurements. This explanation seems to be supported by the fact that the density-crystallinity relation d'_{tot} (Fig. 1), which was obtained in our laboratory from infra-red measurements, leads to much higher crystallinities and can moreover be extrapolated to intersect the d_{rh}-curve at $\varphi = 1$. The line d'_{tot} also agrees with nuclear magnetic resonance measurements made in our laboratory of the 'mobile' fraction in different polyethylene samples at room temperature.

However, the differences between the amorphous fractions following from the lines d_{tot} and d'_{tot}, respectively, seem to be too large to be attributable to experimental errors alone. We believe that the discrepancies must be explained by the above-mentioned suggestion, namely, that also in normal polyethylene a second crystalline modification is present. In the X-ray method this fraction is 'seen' as amorphous, in the other methods as crystalline.

This view is supported by measurements of the integral breadth of the amorphous band, from which it followed that for highly crystalline samples this breadth is only about two-thirds of the value found for molten polyethylene. This agrees with the idea that a (perhaps highly broadened) crystalline peak is hidden under the amorphous band.

If this explanation is assumed, the fraction φ_2 of the second modification may be roughly estimated to correspond with the horizontal distance between the lines d_{tot} and d'_{tot}. Using for the density d_2 of the second modification the value suggested by Teare and Holmes (0·965 gm./cm.^{3}, ref. 1), the amorphous density may now be calculated anew from the relation :

$$\frac{1}{d_{\mathrm{tot}}} = \frac{\varphi_{\mathrm{rh}}}{d_{\mathrm{rh}}} + \frac{\varphi_2}{d_2} + \frac{1 - \varphi_{\mathrm{rh}} - \varphi_2}{d_{\mathrm{am}}}$$

This leads to values of about 0·84 gm./cm.^{3} for all samples, which is in good agreement with the range of values found by extrapolation of the density of molten polyethylene.

I am indebted to Dr. Westrik for many helpful suggestions. The density, infra-red, and nuclear magnetic resonance measurements were made by Dr. Fortuin, Dr. Veerkamp and Dr. Smidt, respectively, who kindly gave me permission to use their results in this discussion.

CHEMISTRY

Preparation of Pure Standard Metallic Perchlorate Solutions

Acid-free standard solutions (0·05 *M*) of the perchlorates of the divalent metals copper, nickel, cobalt, iron, zinc and manganese suitable for use in the determination of stability constants of chelates by the potentiometric method can be prepared utilizing an ion-exchange technique. A column 1·6 cm. diameter containing 50 ml. 'Amberlite' cation exchange resin *IR* 120(*H*) is treated with a solution (0·1 *M*) of the pure sulphate or chloride of the divalent metal until the *p*H's of the entrant and issuing solutions are identical. After eluting the excess metal salt solution with water the metal ions bound to the resin are displaced by passing a pure solution of barium perchlorate (0 052 *M*) on to the resin. Since barium ions have a stronger affinity for the resin than the divalent ions of copper, nickel, cobalt, iron, zinc and manganese, the latter are displaced and the barium-free fractions of the eluates contain the pure perchlorate solutions of these metals. A yield of about 400 ml. 0 05 *M* metal perchlorate solution is obtained under these conditions. An analysis of each of the solutions was carried out using both gravimetric and ion exchange methods. In the latter a 20-ml. portion of the metal was passed on to a small column of 'Amberlite' resin *IR* 120(*H*) and the eluate titrated with standard alkali. The results obtained by the two methods agreed to within 0·3 per cent.

The ferrous perchlorate solution can be conveniently stored in the ion exchange column which, for ease of dispensing, is connected to a burette fitted with an oxygen trap. The solution should be standardized immediately before use and contains less than 10 p.p.m. Fe^{3+}. In order to obtain a maximum yield it is necessary to exclude air from the solutions used for the quantitative conversion of the resin into the form $(RSO_3)_2Fe$. However, while the yield is lowered by the presence of Fe^{3+} on the resin the purity of the ferrous perchlorate is not affected since during the subsequent treatment with barium perchlorate only ferrous ions are displaced from the resin.

Catalytic Effects in the Alkaline Oxidation of Cellulose

Michie and Neale[1] have reported results which suggest that copper has an unexpectedly high catalytic effect in the reaction of cellulose with oxygen in the presence of low concentrations of alkali. By comparing their observed rate of reaction for copper-treated cotton containing fully carbonated sodium hydroxide with a value calculated from Davidson's[2] results for the uncatalysed reaction at high sodium hydroxide concentration, they deduced that the copper increased the rate by a factor of 80 or more. Very much smaller increases, namely, less than tenfold, had been found by other workers, concerned with alkali concentrations of 5 *N* or higher, on addition of metallic catalysts.

A more direct demonstration of a large catalytic effect at fairly high alkali concentration is provided by the results in Fig. 1, which shows the variation of the initial rate of oxygen consumption of jute fibre at 60° C. with the iron content of the fibre. The

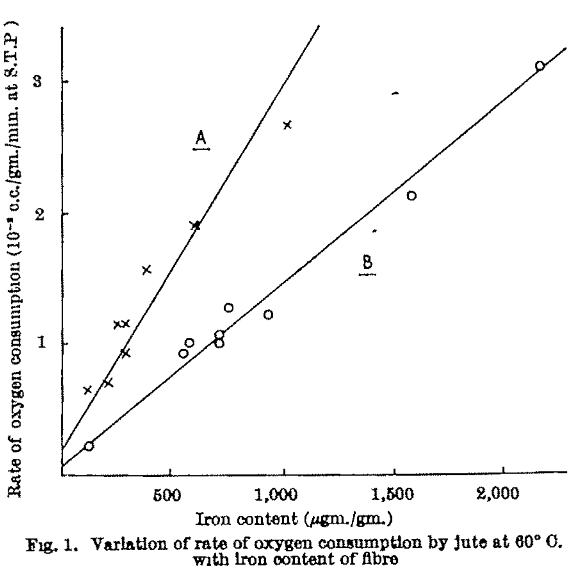

Fig. 1. Variation of rate of oxygen consumption by jute at 60° C. with iron content of fibre

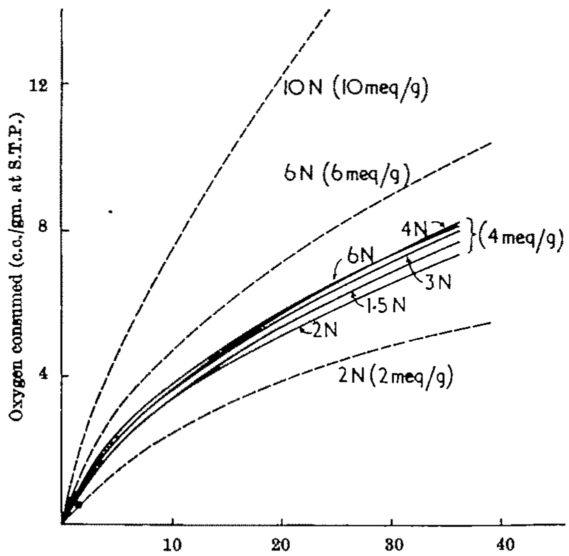

Fig. 2. Oxygen uptake of jute at 60° C. Figures on curves: concentration of sodium hydroxide solution. Figures in brackets: weight of sodium hydroxide per gm. of fibre

natural iron content of jute fibre is normally in the range 250–500 μgm./gm., and the samples used in these experiments included untreated fibre, fibre treated with acid to reduce the iron content, and fibre impregnated with different amounts of ferric sulphate. The rate at which oxygen was consumed by the fibre was determined from the fall in pressure in a closed vessel, filled with pure oxygen, in which the powdered fibre, moistened with a measured volume of sodium hydroxide solution, was spread over the inner surface. The oxygen uptake was normally linear with time over the first few hours and thereafter gradually decreased. An induction period, such as found by Davidson[2] for cotton, was not observed with jute fibre. The rates plotted in Fig. 1 were estimated from the slope of the initial linear portion of the uptake curves. The two lines, *A* and *B*, are drawn through points for two sets of experiments in which different quantities of sodium hydroxide were added to the fibre, as follows:

A, 2·67 ml. 3 *N* sodium hydroxide per gm. of fibre (8 m.equiv. sodium hydroxide/gm.).

B, 1·33 ml. 3 *N* sodium hydroxide per gm. of fibre (4 m.equiv. sodium hydroxide/gm.).

These results demonstrate two points of interest:

(*a*) Over the range of iron contents covered, the rate of reaction increases linearly with the iron content. In the results of set *B* a catalytic factor of about 40 is involved on increasing the iron concentration from zero to the highest experimental iron content of 2,170 μgm./gm. Other experiments at higher iron contents, however, showed that the linear relation did not hold above 2,000 μgm./gm., the rate apparently becoming independent of iron concentration, in agreement with the conclusion reached by Michie and Neale[1].

(*b*) The ratio of the slopes of lines *A* and *B* is very close to 2·0, indicating that the rate of reaction is proportional to the weight of sodium hydroxide per unit weight of fibre and not to the concentration of the sodium hydroxide solution applied to the fibre. This relationship is confirmed by the results in Fig. 2, which shows the uptake of oxygen with time of samples of natural jute fibre moistened with different volumes of sodium hydroxide solutions of various concentrations. The group of solid lines, for a constant weight of 4 m.equiv. sodium hydroxide per gm. of fibre, indicates a rate of oxygen consumption that is constant within the reproducibility of these experiments, although the concentration of the alkali solutions varies from 1·5 *N* to 6 *N*. If this relationship applies to cotton as well as to jute, the finding of Michie and Neale[1] that the rate of oxidation is to a first approximation proportional to the sodium hydroxide concentration would seem to be valid only if equal volumes of alkali solution were applied to a given weight of fibre.

Infra-Red Spectra of Deoxyribonucleic Acids from Human Leucocytes

As part of a study on the physico-chemical behaviour of deoxyribonucleic acid obtained from human leukæmic leucocytes, we have examined the infra-red spectra of many normal and leukæmic samples in solutions in water and deuterium and in the dry state. Since we did not find complete agreement between previous reports of the infra-red spectra of calf thymus deoxyribonucleic acid[1-3], we have also studied samples from this source. The effects of heating, *p*H changes, degradation with deoxyribonuclease, mild and strong acid hydrolysis were examined and the spectrum of apurinic acid has also been determined.

A Perkin–Elmer, model 21, double-beam spectrometer with sodium chloride and calcium fluoride optics has been used. With slit-widths narrower than those used by Blout and Lenormant[4] and with suitable adjustments, we were able to improve the resolution. The deuterium solutions were prepared in the manner described by previous authors[4].

The samples were examined in demountable cells of thallium bromo-iodide with spacers of 0·015 mm. In order to avoid the small lack of compensation due to absorption by atmospheric water in studying details of the bands in the region between 1,700 and 1,500 cm.$^{-1}$, we flushed the spectrometer with dry nitrogen.

The spectra were observed in the regions: dry state, 4,500–650 cm.$^{-1}$; deuterium solution, 2,000–650 cm.$^{-1}$; water solution, 1,500–850 cm.$^{-1}$. All samples of deoxyribonucleic acid from normal and leukæmic sources had identical spectra. The physical or chemical treatments resulted in the same spectral modification for all samples.

The spectrum of deoxyribonucleic acid in deuterium solution, in the region between 1,700 and 1,500 cm.$^{-1}$, shows the following bands: 1,575 cm.$^{-1}$(*w*) with a shoulder at 1,563 cm.$^{-1}$; 1,622 cm.$^{-1}$(*m*); 1,645 cm.$^{-1}$ strong and sharp; 1,680 cm.$^{-1}$ strong and broad.

These results are in agreement with those obtained by DeLozé[3] for calf thymus deoxyribonucleic acid at 100 per cent relative humidity in deuterium, except that we did not find the band at 1,695 cm.$^{-1}$ in any sample.

The physical and chemical treatments mentioned above induce no change in the frequency or shape of the band at 1,575 cm.$^{-1}$, though the band becomes stronger at *p*H 13. This band does not appear in the spectrum of apurinic acid. The band at 1,622 cm.$^{-1}$ has been found in the spectra of all samples: it became sharper after treatment with deoxyribonuclease or upon change of *p*H. For all samples, the band at 1,645 cm.$^{-1}$ completely disappears after acid hydrolysis or treatment with deoxyribonuclease and is replaced by a strong band at 1,660 cm.$^{-1}$. On heating at 100° the band at 1,660 cm.$^{-1}$ becomes broader. The band at 1,680 cm.$^{-1}$ which is strong and broad in the original spectrum decreases considerably, but does not disappear on treatment with enzyme, acid hydrolysis or on heating and there is a frequency shift to 1,690 cm.$^{-1}$. The spectrum of all samples of *p*H 13 shows a new weak band at 1,592 cm.$^{-1}$.

These results are of particular interest in relation to the nature of the specific interaction between purine and pyrimidine units in deoxyribonucleic acid structure[6-9].

Our observations are in disagreement in some respects with previous reports[1], and the explanation of the spectral changes is still open to discussion. Further data are required, and a more detailed study of the spectra changes of deoxyribonucleic acid under different *p*H conditions is now being carried out. The results and a proposed interpretation will be published elsewhere.

In previous determinations of infra-red spectra of deoxyribonucleic acid in mineral oil suspension, preparations of myeloid leukæmia leucocytes were found to exhibit a band which was not present in preparations from normal leucocytes[5]. The results of the present work, however, do not confirm this observation.

We are indebted to Dr. E. Mantica for his interest and helpful discussion.

Use of Solvents containing Ethyl Iodide in the Investigation of Phosphorescence Spectra of Organic Compounds

M. KASHA[1] has suggested that the yellow colour produced when α-chloronaphthalene and ethyl iodide are mixed is due to the enhancement of the lowest singlet–triplet absorption band of the naphthalene molecule. He interpreted this effect in terms of a collisional perturbation of spin-orbital coupling in the aromatic molecule, by the heavy iodine atom. The singlet–triplet absorption bands reported for benzene by a number of workers[2] as well as those for a wide number of other aromatic molecules have been shown by Evans[3] to be due to spin orbit perturbation by the inhomogeneous fields of dissolved paramagnetic oxygen molecules. The perturbing effects of ferric and cupric acetonyl acetonates have also been demonstrated[4].

It was thought that a similar effect of perturbation might be observed during phosphorescent emissions from organic compounds, both by increasing the likelihood of phosphorescent return to the ground-state, and by increasing the conversion from the excited singlet to triplet states. The effect of ethyl iodide on the emissions of the eight isomeric dinitronaphthalenes, and on N,N-dimethyl-4-nitroaniline, coumarin and acid fluorescein was investigated. The phosphorescence spectra were first measured with the compounds dissolved in a glass made by cooling a mixture of four parts of ethanol to one of methanol to the temperature of liquid air. The spectra were then remeasured in a glass containing one part of ethyl iodide to four parts of mixed alcohols. The apparatus used was a high-pressure a.c. mercury arc lamp fed through a rectifier, and a glass prism spectrometer with a photomultiplier at the exit slit. Phosphorescence was identified and recorded by 'chopping' the photomultiplier current supply so that the sample emission was only recorded during the ½ a.c. cycles when the lamp arc intensity was zero. The ratio of the intensities of the readings obtained for a given band with and without the 'chopper' was approximately 1 : 2 for long-lived phosphors. This is because the total luminescence involved viewing for twice the time available for phosphorescence readings. For short-lived phosphors, this ratio was smaller due to the rapid decay of the emission with respect to the time of an a.c. cycle. The results of these investigations are shown in Table 1. 1,5-Dinitronaphthalene is quoted as typical of the dinitronaphthalene series.

Table 1

Compound	Total luminescence : phosphorescence ratio		Life-time (sec.)	
	Alcohol	Alcohol + Et I	Alcohol	Alcohol + Et I
1,5-Dinitronaphthalene	1·97	2·28	> 0 1	0 008
N,N-Dimethyl-4-nitronaphthalene	1·97	2·32	> 0·1	0·008
Coumarin	—	2 94	> 0·1	0 005
Acid fluorescein	—	2·35	> 0·1	0·007

In all cases the effect of the addition of ethyl iodide was to increase the intensity of the phosphorescence bands and increase the ratio of the total luminescence to phosphorescence. Since the phosphorescence intensity did not appreciably decrease, the effect of the iodide on the ratio was not merely to increase the radiationless deactivation to the ground-state, but must also have increased the probability of the triplet–ground singlet transition. This evidence would seem to show that even in a rigid glass solvent 'heavy atom' perturbation occurs, thus providing the inverse effect of Kasha's observations.

Two other effects are of interest: first, the phosphorescence band peaks were shifted towards lower energies by about 200–300 cm.$^{-1}$; and, secondly, the coumarin and acid fluorescein fluorescence intensities were also increased. It is possible that some form of complex might lead to charge transfer effects such as those reported by Reid[5]. These points will require further investigation.

It should be noted that, although ethyl iodide is well known to undergo photolysis in strong ultraviolet light, no appreciable decomposition was found under the conditions of the present work.

We wish to thank Dr. E. J. Bowen for help and encouragement. This work was carried out during the tenure of a maintenance grant from the Department of Scientific and Industrial Research by one of us (J. M. C.).

Rate of Ligand Exchange with its Metal Complex by a Polarimetric Method

OPTICALLY active 1,2-propylenediamine tetraacetic acid[1] (H_4PDTA) co-ordinates in a completely stereospecific manner[2] with Co(III), Rh(III) and Cr(III). Courtauld models of either co-ordinated optical isomer show the methyl group to be sterically hindered for one configuration of the metal complex irrespective of whether the ligand is attached at 4 (non-planar), 5 or 6 points to the metal atom. The absolute stereospecificity of complex formation provides a simple polarimetric method of measuring the exchange-rate of the free ligand with its metal complexes.

Equivalent amounts of the metal complex containing one optical form of the ligand and the free optical antipode were mixed in buffered aqueous solution, and the rate of loss of optical activity determined.

$$[M\ d\text{-PDTA}]^{n-} + l\text{-PDTA} \rightleftharpoons [M\ l\text{-PDTA}]^{n-} + d\text{-PDTA}$$

It will be evident that the rotation will have fallen to zero when half the ligand is exchanged. The concentrations of unreacted initial complex and the added free ligand at any time may be calculated from the observed rotation and the respective initial rotations before mixing. In general, there is a considerable difference between the rotatory powers of the free ligand and the metal complex even when the latter is colourless. The difference may be magnified by a suitable choice of the wave-length of the light when the complex is coloured.

Preliminary studies of the rate of exchange of the cadmium complex with the ligand have shown a first-order dependence on both complex and ligand at *p*H 6. The approximate specific rate constant at 20° C. was found to be 0·07 l.-moles^{-1}-sec.$^{-1}$. During the reaction, the rotation changed from $-0{\cdot}66°$ to zero for 0·005 *M* solutions of complex and ligand in a 20-cm. tube.

Table 1

Complex	*p*H	Time for half-exchange with *l*-PDTA
[Ni(*d*-H_2.PDTA)]	0 70	30 min.
	2 90; 6·40	No exchange in 3 days
[Cu(*d*-H_2.PDTA)]	2 90	< 1 min.
	6·40	16 hr.
[Cd(*d*-H_2.PDTA)]	2 90	<40 sec.
	6 30	1 hr.
[Zn(*d*-H_2.PDTA)]	2·90	<40 sec.
	6 32	3 hr.
[Ca(*d*-H_2.PDTA)]	7 80	< 1 min.
[Al(*d*-H.PDTA)]	2 90	20 hr.
[Y(*d*-H.PDTA)]	2 90	< 1 min.
[Mn(*d*-H_2.PDTA)]	3 00	< 1 min.
	6·30	5 min.
[Co(*d*-H_2.PDTA)]	2·90	< 1 min
	6·30	7 days
[Fe(*d*-H.PDTA)]	0 7	7 hr.
	6 5	No exchange in 2 days

The approximate times for exchange between half of the PDTA and a number of its metal complexes at 20° C. are shown in Table 1. The metal complexes were prepared in the acid forms, [*M*(H_2.PDTA)], or [*M*(H.PDTA)] by reaction between the metal acetate and active propylenediamine tetraacetic acid and, after recrystallization, dissolved in the appropriate buffer solution. The complexes like those with ethylenediamine tetraacetic acid are either quinquidentate or sexadentate. Detailed studies will be published later.

BIOCHEMISTRY

Specific Detection of Glucose on Paper Chromatograms

MIXTURES of monosaccharides derived from complex polysaccharides often present difficulties in identification when the compounds migrate close to one another on paper chromatograms. Difficulties of this kind have been encountered with certain bacterial polysaccharides containing glucose, galactose and heptoses. With the use of the glucose oxidase[1]-indicator reagent, 'Glucostat' (Worthington Biochemical Corporation) it has been possible to locate specifically the glucose and then reveal other monosaccharides on the same paper chromatogram.

Monosaccharides were separated on Whatman paper No. 1, with the *n*-butanol–pyridine–water (6 : 4 : 3 v/v) solvent system, the paper chromatograms dried in air and then sprayed with the 'Glucostat' reagent prepared as for the quantitative estimation of glucose in biological fluids[2]. As the 'Glucostat' reagent is in the form of a buffered, aqueous solution, flooding of the paper chromatograms was avoided to prevent spreading of the various monosaccharides. When sugars were separated with acidic solvents such as *n*-butanol–acetic acid–water (6 : 1 : 2 v/v) the chromatograms were steamed for 5–10 min. before spraying. The indicator dye, *o*-dianizidine, in the 'Glucostat' reagent locates the glucose by turning a permanent pinkish-brown colour. The colour develops rapidly at room temperature and no further treatment is necessary. The method readily detects 10–20 μgm. glucose separated on paper chromatograms and will detect less than 10 μgm. providing little spreading of the 'spot' occurs during chromatography. Attempts to adapt the method for direct quantitative estimation have been unsuccessful, as the coloured complex adheres strongly to the paper and could not be extracted quantitatively in a variety of solvents. Thus, for determination of glucose, it is necessary to elute after separation on paper chromatograms and then develop the colour in the normal manner with the glucose oxidase–*o*-dianisidine reagent[2].

After detection of glucose, the paper chromatograms were dried in air and over-sprayed with aniline phthalate for the identification of other monosaccharides. There is some loss in sensitivity towards reaction with the aniline phthalate, presumably due to the buffer constituents, protein, etc., of the 'Glucostat' reagent. However, for differentiation between glucose and other monosaccharides poorly separated from the former sugar, spraying first with the glucose oxidase reagent and then over-spraying with aniline phthalate provides a rapid and reproducible technique. The recent report of a galactose oxidase[3] suggests that such an enzyme could also be applied in a similar fashion for the specific identification of galactose.

Glutathione Stability and Pyrophosphatase Activity in Reticulocytes; Direct Evidence for the Importance of Glutathione for the Enzyme Status in Intact Cells

In the course of studies on the maturation of red blood cells we confirmed the report of Malkin and Denstedt[1] that reticulocytes show a tenfold higher activity of inorganic pyrophosphatase as compared with erythrocytes. Pyrophosphatase appears to contain a functional SH— group. Traces of cupric ions, *para*-chloromercury benzoate and iodo-acetate cause an inhibition which is reversible by cysteine[2,3]. To test the assumption that the lability of the SH— group may be connected with the decrease of pyrophosphatase activity during maturation, the effect of conditions which change the oxidation status of glutathione on the activity of pyrophosphatase was studied.

The experiments were performed on intact cells and hæmolysates of rabbit blood, in which a reticulocytosis of 35–40 per cent was brought about by bleeding. Table 1 contains the results of an experiment on intact cells in which phenylhydrazine was employed to oxidize the glutathione according to Beutler's procedure[4]. It may be seen that incubation of washed cells without phenylhydrazine did not occasion a decline of pyrophosphatase activity; this did occur in the presence of phenylhydrazine. Addition of glucose prevented the loss of enzyme activity. In Table 2 is shown a similar experiment on stroma-free hæmolysate. Here the loss of enzyme activity could be prevented by the addition of glucose-6-phosphate. The mechanism of the action of phenylhydrazine is in all likelihood a hæmin-catalysed oxidation of glutathione[5,6]. The conservation of glutathione with glucose or glucose-6-phosphate occurs by way of the chain of enzymes hexokinase, glucose-6-phosphate-dehydrogenase and glutathione reductase[7].

Table 1

Phenylhydrazine	—	—	+	+
Glucose-6-phosphate (5×10^{-3} *M*)	—	—	—	+
Pyrophosphatase units	25 9	22·1	8·2	22·1

In the following experiments the direct effect of oxygen was studied and further evidence for the depicted course of events was sought. Table 3 records an experiment in which hæmolysates with and without stroma, which had been dialysed for 60 hr., were incubated. It may be seen that oxygen alone in the presence of stroma caused more than 85 per cent loss of enzyme activity (II). The addition of glutathione alone (IV) diminished the inactivation only to a small extent. Addition of glucose-6-phosphate (VII) also showed only incomplete stabilization of pyrophosphatase. In the presence of nicotinamide (VI), presumably by virtue of inhibition of triphosphopyridine-nucleosidase[8], a higher degree of stabilization was observed. In a complete system (V), complete stabilization was achieved. In the absence of stroma the decrease of enzyme activity was much less (2), and the addition of glutathione alone (4) was sufficient for stabilization. The experiments not only prove that oxygen without intervention of phenylhydrazine may oxidize glutathione but also show that stroma, probably by way of autoxidation of the unsaturated fatty acids, combined with the action of hæmin[9], may favour this oxidation. In addition, stroma increases the inactivation by way of destruction of triphosphopyridine nucleotide through its enzyme. The partial stabilization of pyrophosphatase without addition of triphosphopyridine nucleotide is in consonance with the report of Carson[10], which showed the triphosphopyridine nucleotide is tightly bound to glucose-6-phosphate dehydrogenase.

Pyrophosphatase units	13·2	16·5	6·6	12·7	1·2	2·9

* x, y from another experiment, activity without incubation, 18·7.

In Table 4 is shown the fact that the inactivation of pyrophosphatase is to a large extent reversible by addition of cysteine after a short period of incubation. The conclusions of these experiments may be summarized as follows.

The stability of pyrophosphatase in the reticulocytes is closely linked with glutathione, which is maintained in the reduced state by way of the oxidation pathway of glucose-6-phosphate. Eliminations or blocking of any single step in the chain may cause a stoichiometric oxidation of glutathione with conequent loss of activity of pyrophosphatase.

Oxidation of glutathione leads to a denaturation of pyrophosphatase, the first reversible step of which is formation of disulphide-bonds. Thus there is close interaction between metabolic processes, such as are concerned with the maintenance of glutathione, and the structural changes of denaturation.

The experiments reported are, so far as we know, the first instance of a direct effect of glutathione on the activity of an enzyme within an intact cell. Other SH— enzymes are in progress.

The mechanism described may have general importance for the conservation and the decline of enzymes in the processes of differentiation and maturation of cells.

Characterization of a New Purine Riboside isolated from *Fusarium* Species

AN investigation of the acid-soluble nucleotides occurring in a *Fusarium* species[1] has shown that, in addition to a number of previously known compounds, several new ultra-violet absorbing substances are present in this mould. One of these was identified as the mononucleotide of nicotinic acid[2], a compound which has also been isolated from baker's yeast[3]. The present communication reports the characterization of a second substance, an N^2-substituted guanosine which is probably 2-(1-carboxyethylamino)-6-hydroxy-9-β-D-ribofuranosylpurine.

The compound was isolated from perchloric acid extracts of the micro-organism by ion exchange chromatography[4] and purified by paper chromatography. From a 50-l. culture grown in a stirred fermentor[5] on Czapek–Dox medium 2·5 μmoles were obtained, as calculated from the pentose content of the chromatographically pure substance. The product was phosphorus-free and had ultra-violet absorption spectra at different *p*H values very similar to those of guanosine, except for a small bathochromic shift of the maxima and the minima. Paper electrophoresis in 0·1 *M* ammonium acetate, *p*H 6·5, indicated the presence of a negatively charged group. The orcinol reaction for pentoses was positive; the pentose was liberated on acid hydrolysis (2 hr. at 100° C. with 1 *M* hydrochloric acid) and identified as ribose by paper chromatography in *n*-butanol–acetone–water (2 : 7 : 1, v/v/v). The ribose moiety of the new compound had the furanosidic structure, as shown by the formation of glycerol after degradation according to the procedure of Viscontini, Hoch and Karrer[6] scaled down to 0·3 μmole[7]. Acid hydrolysis yielded, in addition to ribose, an ultra-violet absorbing compound which was purified by ion exchange and paper chromatography. It gave a negative reaction for pentoses, had ultra-violet spectra at acid, neutral and alkaline *p*H values nearly identical to those of 6-hydroxy-2-methylaminopurine[8], and paper electrophoresis indicated the presence of an acidic group. When heated with 4 *N* formic acid (15 hr. at 125° C.) it yielded guanine, which was identified by paper chromatography in two solvent systems and by its ultra-violet spectrum.

These results strongly suggested that the compound isolated from the mould was the ribofuranoside of an N^2-substituted guanine containing an acidic group. The close similarity of the ultra-violet spectra of the hydrolysed compound to those of 6-hydroxy-2-methylaminopurine indicated that the acidic group was most likely carried by the N^2-substituent, so that the aglycone would be an N-(6-hydroxy-2-purinyl)-amino-acid. To test if this were correct a number of compounds of this type were synthesized by treating at *p*H 8·5–9·0 aqueous solutions of 2-chloro-6-hydroxypurine[8] with each of 22 amino-acids in sealed tubes for about 15 hr. at 110–125° C. The amino-acids used were α- and β-alanine, α-, β- and γ-aminobutyric acid, ε-aminocaproic acid, β-amino*iso*butyric acid, aspartic acid, glutamic acid, glycine, *iso*leucine, leucine, methionine, S-methylcysteine, norvaline, phenylalanine, sarcosine, serine, taurine, threonine, tyrosine, valine. The ultra-violet spectra of the synthetic compounds were practically identical to those of the natural aglycone, except for that of the compound prepared from sarcosine, which showed a remarkable bathochromic shift of the maxima at acid and neutral *p*H values (a similar behaviour is shown by 2-dimethylamino-6-hydroxypurine, as compared with 6-hydroxy-2-methylaminopurine[8]) and for that of the compound prepared from tyrosine, which is strongly influenced by the amino-acid chromophore.

When the paper electrophoretic and chromatographic mobilities of the synthetic compounds were determined, a definite correlation with some chemical features of the N^2-substituent was found. Among the whole set of model substances prepared, only those obtained by treating 2-chloro-6-hydroxypurine with α-aminomonocarboxylic acids behaved electrophoretically as the natural purine. This, moreover, could be distinguished from all of the synthetic compounds, except for the α-alanine and threonine derivatives, by paper chromatography in two solvent systems. In order to decide which, if either, of these two products was identical with the aglycone of the ribo-

* With the exception of solvents 6 and 7, descending chromatography was used. Solvents were: No. 1, *iso*propanol–12·5 *M* hydrochloric acid–water (170 : 41 : 44, v/v/v) ; No. 2, *iso*butyric acid–1 *N* ammonia (100 : 60, v/v) ; No. 3, ethanol–1 *M* ammonium acetate, *p*H 3·8 (75 : 30, v/v) ; No. 4, as No. 3, but *p*H 7·5 ; No. 5, *n*-propanol–water (70 : 30, v/v) ; No. 6, 16 per cent ammonium bicarbonate ; No. 7, ammonium sulphate–*n* propanol–0·1 *M* phosphate buffer, *p*H 6·8 (600 gm. : 20 ml. : 1,000 ml.) ; No. 8, *n*-propanol–16 *M* ammonia–water (60 : 30 : 10, v/v/v).

side isolated from the mould, a number of chromatograms were run with different solvent systems. A satisfactory separation was achieved in ammonium sulphate–*n*-propanol–0·1 *M* phosphate buffer, *p*H 6·8 (600 gm. : 20 ml. : 1,000 ml.). In this solvent the threonine derivative gave a single spot, whereas the α-alanine derivative divided into two spots, a behaviour also observed with its next higher homologue, that is, the α-aminobutyric acid derivative. The natural aglycone also gave two spots having the same R_F values as the synthetic α-alanine derivative.

In conclusion, the natural base and the synthetic compound prepared from α-alanine and 2-chloro-6-hydroxypurine appeared to be identical when compared by paper chromatography in eight solvent systems, by paper electrophoresis at four different *p*H values and by ultra-violet absorption spectra (Table 1). Furthermore, both gave guanine when heated with 4 *N* formic acid.

The evidence described above is probably the most that could reasonably be obtained with the minute amount of material available ; on this basis it is proposed to assign provisionally the structure of 2-(1-carboxyethylamino)-6-hydroxy-9-D-ribofuranosylpurine to the new nucleoside isolated from *Fusarium*. The configurations of the amino-acid residue and of the ribose-base linkage are unknown, but it is probable that the latter is β-D by analogy with the majority of nucleosides and nucleotides found in Nature. The close similarity of the ultra-violet spectra of the nucleoside with those of guanosine[10] and of the riboside of 6-hydroxy-2-methylaminopurine[11] suggests that the ribose is linked to the 9 position of the purine base.

We are indebted to Prof. E. B. Chain for his interest and encouragement throughout this investigation, and to Dr. Gertrude B. Elion for samples of methyl-substituted guanines.

Role of the Triplet State in the Photoreduction of Chlorophyll

IN 1948, Krasnovsky reported[1] that chlorophyll can be photochemically reduced, in dry pyridine, by ascorbic acid. The product is a pink pigment. The quantum yield of the reaction was not measured ; but indirect evidence[2] indicates that it was of the order of magnitude of 10^{-3}. The reaction is reversible ; the green colour of the solution returns slowly on standing, or more rapidly if a suitable oxidant is added. The regeneration of chlorophyll is never complete ; part of it being converted into phæophytin. This and analogous photochemical reactions were studied extensively, in subsequent years[3], by Krasnovsky and Evstigneev *et al.* They have adopted the view that the reversible photoreduction of chlorophyll plays an essential part in photosynthesis and in chlorophyll-sensitized reactions *in vitro*.

The photochemical reduction must involve a direct reaction between an excited molecule of chlorophyll and a normal molecule of the reductant. Evstigneev *et al.*[4] demonstrated that ascorbic acid does not appreciably quench the fluorescence of chlorophyll, dissolved in pyridine. Since this eliminates the possibility that the first excited singlet state reacts directly with ascorbic acid, it has been postulated that the lowest triplet state undergoes this direct reaction. However, Fujimori and Livingston[5] were unable to detect any effect of ascorbic acid (at concentrations as high as 0·10 *M*) upon the rate of decay of the triplet state of chlorophyll, when the solvent was dry pyridine.

Recent work of Bannister[6] suggests a possible way of reconciling these apparently incompatible observations. He demonstrated that chlorophyll is not measurably reduced when it is illuminated in air-free, dry pyridine containing ascorbic acid. The reduction is readily detectable if the solvent contains 2 per cent, or more, of water. In pyridine containing 30 per cent of water and 0·10 *M* ascorbic acid, the quantum yield of photoreduction is about 0·10. Under these conditions, the pink pigment does not accumulate, and oxidation does not restore chlorophyll but produces phæophytin. When the water content is 2 per cent, the quantum yield is several-fold lower, but the reaction is much more nearly reversible. These observations indicate that Krasnovsky's[1] supposedly dry pyridine contained an appreciable amount of water (possibly about 2 per cent).

We have measured the quenching of the triplet state of chlorophyll by ascorbic acid in pyridine, either dried with calcium hydride or containing a known concentration of water. All solutions contained 5×10^{-6} M chlorophyll a and were carefully deoxygenated. Confirming the published results of Fujimori and Livingston, we were unable to detect any quenching of the triplet in dry pyridine; however, in the presence of water, ascorbic acid unmistakably quenches the chlorophyll triplet. Our preliminary results are given in Table 1.

Table 1

k_{I}, sec.$^{-1}$ dry, no Q	k_{I}, sec.$^{-1}$ dry, Q added	k_{I}, sec.$^{-1}$ wet, Q added	$[Q]$ moles/l	Water (per cent)	$k_Q \times 10^{-3}$ moles^{-1}/l./sec.$^{-1}$
850	750	3,400	0 0076	22 7	3·4
970	890	2,900	0·0017	22 6	10 0
780	780	2,450	0·0110	2 2	1 5

The rate of disappearance of the chlorophyll triplet conforms to the following equation[5,7], where $[GH]$, $[GH']$ and $[Q]$ represent the concentrations of ground-state chlorophyll, triplet-state chlorophyll and ascorbic acid, respectively, and $m = [GH] + [GH']$.

$$
\begin{aligned}
-\frac{d[GH']}{dt} &= (k_1 + k_2[GH'] + k_3[GH] + k_Q[Q])[GH'] \\
&= (k_1 + k_3 m + k_Q[Q])[GH'] + (k_2 - k_3)[GH']^2 \\
&= k_{\mathrm{I}}[GH'] + k_{\mathrm{II}}[GH']^2
\end{aligned}
$$

The averages of the numbers in the first two columns, 870 and 790, do not differ significantly, and what difference there is between them is in the wrong sense to be explicable in terms of quenching by ascorbic acid. The mean of the values of k_{I}, 840 sec.$^{-1}$, should be compared to the published values of k_1 and k_3 (ref. 7), as follows:

$$730 \text{ sec.}^{-1} + 2{\cdot}3 \times 10^7 \text{ sec.}^{-1} m^{-1} \times 5 \times 10^{-6} m = 850 \text{ sec.}^{-1}.$$

The agreement is fortuitously close. The quenching constants, k_Q, were obtained by dividing the difference between the values given in the first and third columns by $[Q]$. The spread of these preliminary values of k_Q is greater than would be predicted in terms of the reproducibility of the individual measurements. It suggests that, in the range investigated, k_Q is a function of the water content and possibly of the concentration of ascorbic acid. In spite of this uncertainty, the results establish the reality of the quenching by ascorbic acid in wet pyridine and show that it is about ten thousand-fold less efficient than the quenching by oxygen, quinone, etc.[5].

In the presence of water and ascorbic acid, flash illumination produces a long-lived form of chlorophyll in addition to the triplet state. Since its mean life is about 0·01 sec. and it absorbs more strongly at 4800 than at 5200 Å., it cannot be Krasnovsky's[1] pink pigment, but may be one of the 'electrode active' intermediates which were discovered by Evstigneev *et al.*[4].

The available evidence demonstrates that the photoreduction of chlorophyll cannot be an essential step in efficient, chlorophyll-sensitized photochemical reactions occurring in ordinary organic solvents. However, it is not justifiable to draw a similar conclusion about the photosynthesis of plants.

This investigation was made possible by a Research Grant (*A*-2733) from the Division of Arthritis and Metabolic Diseases of the United States Public Health Service.

PHYSIOLOGY

A Phenylthiocarbamide Test

425 BELGIANS (225 males and 200 females) were tested with phenylthiocarbamide and quinine following the technique of Harris and Kalmus[1,2]. Fisher's linear discriminant function was used to class the subjects as tasters and non-tasters. The chi square test for smoking habit gives no significant result, but the influence of sex and age is important as proved by a homogeneity test (Fisher 2 × 10 table for sex; $\chi^2 = 40{,}905$ with 5 d.f.) and a 'Student' test for the mean threshold for $\bar{T}$ and $\bar{t}$, males and females. ($t = 5{\cdot}04$ for $\bar{T}$ and $t = 3\ 258$ for $\bar{t}$.) The correlation coefficient between age and phenylthiocarbamide is:

$$r = -0{\cdot}390 \pm 0{\cdot}109 \text{ for non-tasters}$$

$$r = +0{\cdot}032 \pm 0{\cdot}078 \text{ for tasters}$$

General results are summarized in Table 1.

Table 1

	Males	Females
n	225	200
Age	18–71 y.	14–26 y.
Number (t)	61	44
Frequency (t) (per cent)	27·11	22 00
Gene frequency (t)	0·521	0 469
Phenylthiocarbamide		
Mean total sample	7·498 ± 0·217	8·320 ± 0·247
Mean tasters	9·268 ± 0·107	10 045 ± 0 100
Mean non-tasters	2 738 ± 0·225	2 205 ± 0 180

Creteur obtained in 1952, with a different technique, 28·8 per cent of non-tasters among 679 subjects[3].

Passage of Insulin through the Wall of the Gastro-intestinal Tract of the Infant Mouse

Mosinger, Placer and Koldovsky[1], in a recent communication, have shown that insulin administered orally to suckling rats 2 and 8 days old causes a large drop in blood-sugar levels, but does not do so in 21- and 30-day old rats. Previously I had found that the gut of the 8-day old mouse is permeable to insulin but that this permeability declines thereafter. This work was quoted by Halliday[2] and, although Mosinger *et al.* refer to that paper, they do not mention my findings.

LAB grey mice were used, the young being removed from the mother 2 hr. before the administration of insulin and kept in an incubator at 37° C. for the duration of the experiment. Administration was direct to the stomach with a polythene tube on a tuberculin syringe. Injections were made intraperitoneally. The insulin used was standard crystalline insulin (B.D.H., *A.* and *H.* 22 units/mgm.) dissolved in 0·9 per cent saline acidified with hydrochloric acid to *p*H 2·5. Controls were given an equivalent dose of acidified saline. Observation of convulsions and death did not provide a satisfactory method of measuring the passage of the intact insulin molecule through the gut wall, as infant mice survived hypoglycæmia far longer than did adults. This agrees with the findings of Himwich, Fazekas and Hamburger[3], who showed that in the rat the capacity of the infant brain to endure hypoglycæmia is associated with its lower cerebral metabolic requirement. Therefore, estimations of serum sugar were undertaken. Repeated bleedings of 8-day old mice necessitated micro-methods of sampling and estimation. Blood samples each of *c.* 5 µl. were taken from the tail into capillary tubes before administration of the hormone, and at 30 min. and 60 min. after. The tubes were sealed and stored at 4° C. until tested. The serum was separated by centrifugation and 2-µl. samples tested in duplicate by the method of Stern and Kirk[4]. An 'Agla' micrometer syringe was used for the titrations.

The results are shown in Fig. 1. It is evident that the majority show a significant fall in serum sugar at 7, 8 and 16 days, and that only a small minority show this at 22 days. At 8 days of age, doses of 1 unit/gm. may be effective. At 22 days even doses of 8–10 units/gm. usually have no effect. It is evident from these results that the gut of the suckling mouse at 8 days, and even at 16 days, is permeable to insulin administered orally in very large doses, and that this permeability has almost disappeared at 22 days. The disappearance of permeability to insulin appears to occur rather later and to be less clear-cut than that to antibodies in the suckling mouse. The doses necessary are enormous in comparison with those of the order of 0·001 unit/gm. which are effective by parenteral injection. The wide individual variation in response to the oral administration of insulin at all ages studied is surprising, and for this I have no explanation to offer.

I am indebted to Prof. F. W. R. Brambell and Mr. W. A. Hemmings for their interest and advice during the course of this work.

Seasonal Differences in Ovulating Hormone in the Merino Ewe

Cessation of cyclic ovarian activity in ewes during anœstrus is thought to be associated with changes in the level and/or type of gonadotrophic substances reaching the ovary[1]. This supposition cannot be tested by direct means at the present time, but a recently developed technique for synchronization of ovulation in ewes[2] suggests possibilities of an indirect examination.

Merino ewes were injected daily with 10 mgm. of progesterone in oil intramuscularly for 14 days in either April (the middle of the breeding season) or October (anœstrus). At the same time as the final progesterone injection each ewe received 500 I.U. of pregnant mare serum gonadotrophin subcutaneously. 48 hr. later groups of ewes were injected with either 300 I.U. of human chorionic gonadotrophin intra-

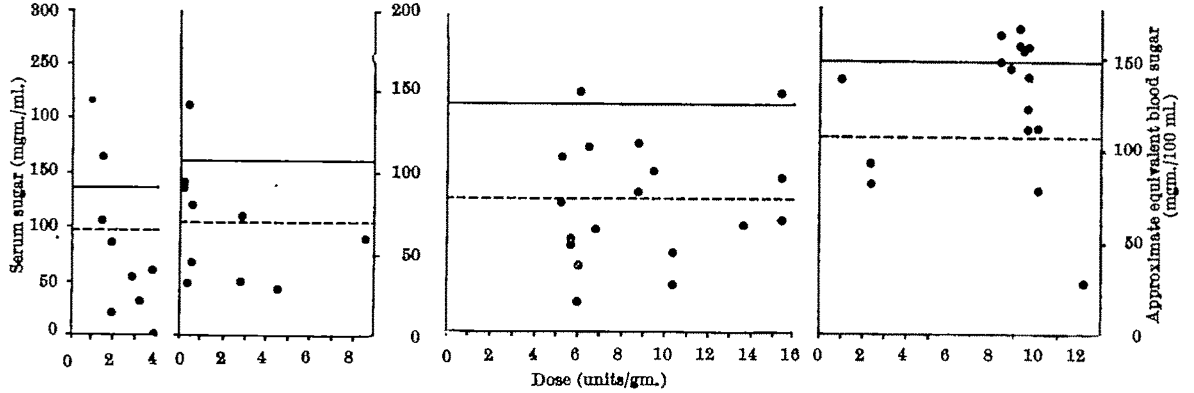

Fig. 1. Values of serum sugar in mgm./100 ml. 60 min. after oral administration of insulin to young mice of 7, 8, 16 and 22 days of age according to dose in units/gm. The corresponding approximate scales for blood sugar are inserted on the right for comparison with the serum sugar scale on the left; the blood sugar values being derived from the hæmatocrit values of 33 per cent for 8-day and 42 per cent for 16- and 22-day-old mice. The solid horizontal line represents the mean serum sugar-level before the administration of insulin and the broken line the value below which individual experimental results may be considered significant at the 5 per cent level

Table 1. TIME OF OVULATION IN MERINO EWES

All ewes received 10 mgm. of progesterone intramuscularly daily for 14 days and 500 I.U. of pregnant mare serum gonadotrophin on the fourteenth day. The human chorionic gonadotrophin was given 48 hr. after the pregnant mare serum gonadotrophin

Season	Human chorionic gonadotrophin (I.U.)	No. of ewes		Ovulations occurring in following periods after human chorionic gonadotrophin					Mean time of ovulation (hr.)

muscularly, or 900 I.U. intramuscularly, or 300 I.U. intraperitoneally. Laparotomy, which seems not to influence the time of ovulation[2], was performed 22, 29 and 44 hr. after the injection of human chorionic gonadotrophin. All ewes used in October were carrying eleven months wool but half were shorn 1–2 hr. prior to the injection of human chorionic gonadotrophin.

The treatment groups are shown in Table 1 together with the numbers of ovulations observed at the various times of laparotomy and the estimated mean time of ovulation for each group. The times of ovulation were estimated by visual examination. Ovulations which seemed to take place during the periods 19–32 hr. and 41–47 hr. were estimated to the nearest 1–2 hr.; others were estimated to the nearest 6–8 hr. The within-group variances were significantly greater in October ($\chi^2_{(1)} = 8·78$, $0·001 < P < 0·01$) hence the two sets of data were analysed separately. A summary of the analyses is appended to Table 1.

The mean time of ovulation following 900 I.U. intramuscularly of human chorionic gonadotrophin was apparently constant at the two times of the year ($P = 0·6$). A difference of approximately 20 hr. in the time of ovulation following 300 I.U. of human chorionic gonadotrophin intramuscularly suggests that during anœstrus there was present, at or soon after the time of injection, smaller amounts of a substance or combination of substances which acts in conjunction with human chorionic gonadotrophin to hasten ovulation in the breeding season. That the substance(s) is similar to human chorionic gonadotrophin is borne out by the response to the higher dosage-level, and since human chorionic gonadotrophin is generally thought to be similar to ovulating hormone[3] it is possible that there are seasonal differences in the endogenous production of ovulating hormone in Merino ewes. On this basis the greater variation in response in October suggests that individuals in this strain of Merino differ widely in the 'depth' of anœstrus.

In studying the hypothesis the following factors should be taken into account: (*a*) Pregnant mare serum gonadotrophin, given at the time of the final progesterone injection and known to be present in the blood of animals for several days, may influence the ovulatory response to human chorionic gonadotrophin. (*b*) Ovulation may be inhibited by high dosage-levels of human chorionic gonadotrophin[4]. (*c*) The rate of maturity of Graafian follicles after a constant progesterone – pregnant mare serum gonadotrophin treatment may be influenced by the time of year.

I am indebted to Dr. A. W. H. Braden, Commonwealth Scientific and Industrial Research Organization, Prospect, for helpful discussion.

Oxygen Consumption in Cattle in Relation to Rate of Increase in Environmental Temperature

IN determining the responses of cattle to high, controlled temperatures, one of two procedures has usually been employed. Either the cattle were exposed for periods up to 7 hr. to temperatures ranging up to 110° F. (ref. 1), or they were exposed initially to lower temperatures which were increased progressively by small steps at 2-week intervals[2]. As there was some doubt as to whether cattle would react similarly to these two procedures, it was decided to subject the same animals to both types of heat exposure. It was hoped that this comparison would clarify any difference in the reactions of the animals produced by acclimatization or stress effects.

The specific objective of this experiment was to compare the changes in energy-levels (oxygen consumption) of cattle subjected to both acute and progressive types of heat stress.

Nine animals, including 3 Jersey, 3 Holstein and 3 Brown Swiss female calves, which had been raised at a constant temperature of 50° F., were available. At the beginning of the three treatments, shown by the three curves in Fig. 1, this group had reached 14 months of age. The results for all three breeds were

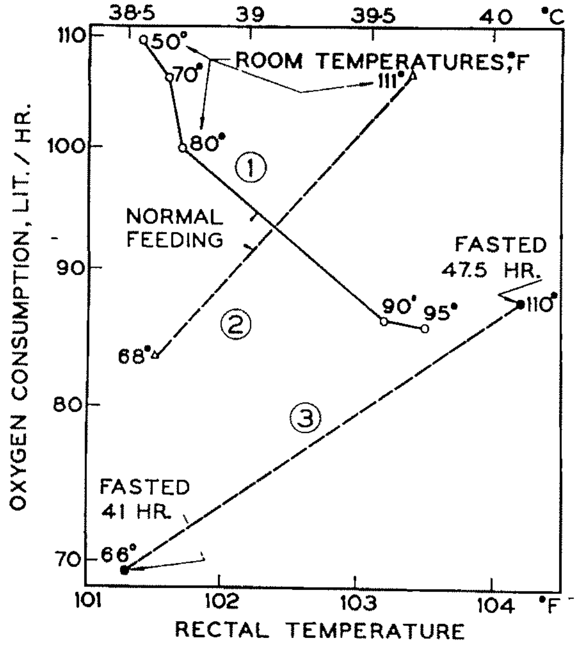

Fig. 1. Differences in the rates of oxygen consumption of cattle resulting from gradual and rapid changes in environmental temperature. Each plotted mean includes 18 observations for curves 1 and 3, and nine observations for curve 2

pooled since the changes with treatment were of primary interest. Oxygen consumption and pulmonary ventilation were measured with an open-circuit metabolism apparatus, which has been described in an earlier publication[3].

In the treatment which resulted in curve 1, the animals were kept for successive 2-week periods at 50°, 70°, 80° and 90° F., and for 4 days at 95° F. During this 2-month period of rising environmental temperature, the rectal temperature increased 2·1 deg. F. At the same time, the oxygen consumption decreased from 110 to 85 l./hr., even though the pulmonary ventilation increased from 49 to 129 l./min. and the body-weight increased from 347 to 365 kgm. Increased hydration may have been a factor in increasing the body-weight, as the plasma protein concentration decreased during this period[4]. The factors which tended to increase oxygen consumption, such as the greater muscular exertion required for high respiratory activity, the increased maintenance for greater body-weight, and the van't Hoff effect incident to high body-temperature, were obviously more than offset by decreases in thyroid activity[5] and consumption of total digestible nutrients (Johnson, H. D., and Ragsdale, A. C., unpublished work). The reduction in feed consumption at high temperatures was voluntary since feeding (except grain) was *ad libitum*.

Curve 2 for these same 9 animals shows that the effect of rapidly rising temperature on oxygen consumption was opposite to that of slowly rising temperature. Measurements made after the morning feeding at a room temperature of 68° F. were not as high as those made 5 hr. later after the room had been heated to 111° F. During the 5-hr. heating period, rectal temperature increased 1·9 deg. F., pulmonary ventilation increased from 45 to 140 l./min. and oxygen consumption increased from 83 to 107 l./hr. (significant at 0·05 level). The rise in oxygen consumption can be attributed to an increase in the muscular exertion of respiration, and the van't Hoff effect. The rapidity of heating the room and the cattle would tend to prevent a depression of any consequence by slow-acting factors. The available nutrients would remain relatively unchanged in a ruminant even though the appetite were depressed by the heat. It seems unlikely, also, that depression of thyroid activity was a major factor.

To eliminate effects of specific dynamic action related to time after feeding, the nine animals were fasted for 41 hr. at 65° F. temperature. Measurements were made at this time at a temperature of 66° F. and again 6½ hr. later after the room had been heated to 110° F. Averages of two such sets of fasting results are shown in curve 3. The 44 deg. F. rise in room temperature increased rectal temperature 2·9 deg. F. and pulmonary ventilation from 33 to 143 l./min. Oxygen consumption increased from 69 to 87 l./hr. (significant at 0·01 level). This rise in oxygen consumption was associated with increased respiratory activity and the van't Hoff effect. There is also the possibility that the combined stress effects of fasting and great heat may have elicited a particular group of reactions called by Selye[6] "the general adaptation syndrome". One of the main characteristics of this syndrome is hypersecretion of adrenal hormones including adrenaline, which is known to increase oxygen consumption in small animals.

Whatever mechanisms are involved, these results indicate that the reactions of cattle to high temperatures may differ with the rate of increase in environmental temperature. Gradual increases in temperature, within limits, depress oxygen consumption. Rapid increases in temperature elevate oxygen consumption.

This experiment was conducted in the Climatic Laboratory, Columbia, Missouri, as one part of a co-operative project between the University of Missouri and the Agricultural Research Service, United States Department of Agriculture.

Release of Methionine labelled with Sulphur-35 from Muscle Tissue and Mitochondria

Continuous renewal of the protein molecule is effected by balance between the incorporation and the removal of amino-acids. From these two processes incorporation has been examined and some intermediate reactions are already known. So far as the second process, that is, intracellular degradation of proteins, is concerned, only basic experiments have been made. Simpson[1] and Steinberg and Vaughan[2] found, for example, that anaerobiosis and 2,4-dinitrophenole inhibit the release of labelled amino-acids from prelabelled liver slices. The degradation of proteins was also found to be dependent on energy-yielding activity of the cell in homogeneous cultures of bacteria[3] as well as animal cells[4]. In subcellular particles, Korner and Tarver[5] found that anaerobiosis and 2,4-dinitrophenole inhibit the release of amino-acids from nuclei and mitochondria. The release from microsomes under the same conditions, however, is stimulated.

In the present communication the intracellular degradation of muscle proteins was studied. We have measured the release of methionine labelled with sulphur-35 from isolated rat diaphragm and from muscle mitochondria. 24 hr. before the experiment the rat received 150 μc. of ^{35}S-methionine per 100 gm. body-weight by intraperitoneal injection. Trichloracetic acid-soluble ^{35}S-methionine in one-half of the diaphragm and in a sample of mitochondria served as initial values. The remaining parts were incubated. The increase of free labelled methionine after 3 hr. incubation of the diaphragm and 2 hr. incubation of mitochondria under usual conditions was determined. This amount was then expressed in percentage protein-bound ^{35}S-methionine.

The mitochondria or homogenated diaphragm were extracted with trichloracetic acid in final concentration of 5 per cent. Following acid hydrolysis, labelled methionine of the protein precipitate was separated from cystine and cysteine by their precipitation as mercaptides. The amino-acids in neutralized trichloracetic acid extract of tissue (or mitochondria) and medium were concentrated on 'Dowex-50'. Taurine and sulphate pass through. Amino-acids were then eluted, and, after acid hydrolysis, cystine, cysteine and homocysteine were precipitated as mercaptides. Methionine of protein as well as of the trichloracetic acid extract was oxidized to sulphate and radioactivity was measured in benzidine sulphate precipitate with an accuracy of 2·5 per cent.

The results given in Table 1 demonstrate that the amount of labelled methionine released from both diaphragm and mitochondria is higher in a medium with 2-4-dinitrophenole and under anaerobic conditions. (The activity of proteolytic enzymes measured at pH 3 6 and 9·0 is not changed under these conditions.) On the contrary, the amount of labelled methionine released from liver mitochondria is, as in the experiments of Korner and Tarver[5], depressed. (Protein degradation, with the exception of release of labelled methionine, was measured on the basis of non-protein nitrogen and amino-acids increase and in the diaphragm also on the basis of non-collagenous proteins decrease. The same results are obtained by all these methods)

Table 1. RELEASE OF METHIONINE LABELLED WITH SULPHUR-35 FROM RAT DIAPHRAGM AND MITOCHONDRIA UNDER DIFFERENT CONDITIONS OF INCUBATION

† Krebs-Ringer bicarbonate buffer containing 200 mgm. per cent glucose and carrier methionine in conc. 0·12 mgm./ml. Gas phase was 95 per cent oxygen and 5 per cent carbon dioxide.

‡ *p*-Fluoro-phenylalanine.

§ 3 ml of medium contained: 50 μ*M* potassium succinate, 20 μ*M* adenosine triphosphate, 0 01 *M* potassium phosphate buffer of pH 7·4, 0 005 *M* magnesium chloride, 0 003 *M* ethylenediamine tetraacetic acid and 1 ml. of mitochondria suspension in 0·25 *M* sucrose. Isotonicity was maintained by adding potassium chloride. Concentration of carrier methionine was 0·12 mgm./ml. Gas phase was oxygen.

Furthermore, a different reaction of liver and muscle tissue was observed after the action of amino-acids antagonist. While the release from liver slices is inhibited by p-fluoro-phenylalanine[1,2] it is stimulated from diaphragm.

The present results demonstrate that the degradation of muscle proteins is enhanced under conditions which limit the utilization of energy. This is quite contrary to the findings in tissues studied up to now (namely, liver and kidney slices, reticulocytes and macrophages). For these cells it was assumed that the degradation of protein involves a complex acceptor substance rather than water. The formation of this complex is dependent on energy. On the contrary, the degradation of muscle proteins is given rather by hydrolytic splitting of peptide bonds by tissue cathepsins.

What is the mechanism by which the effect of the inhibitors of oxidative processes is realized in our experiments? If it is not by influencing the activity of tissue cathepsins, they must affect some other reaction which then makes proteins more accessible to the hydrolytic action of cathepsins. It is important to note that not only inhibitors of oxidative processes but also antagonists of amino-acids stimulate the release of labelled methionine from isolated diaphragm. It is possible that the intracellular degradation of muscle proteins is always stimulated under conditions of inhibition of proteosynthesis.

Duration of Stimulation of Phagocytic Activity of the Reticulo-Endothelial System after Cessation of Treatment with Diethylstilbœstrol

NICOL *et al.* have reported previously that diethylstilbœstrol is a strong stimulant of the phagocytic activity of the reticulo-endothelial system[1]. The present research was designed to ascertain the period of time during which the stimulative effect would persist after cessation of treatment with diethylstilbœstrol.

The following experiments were carried out on 80 male white mice (*T.O.* Swiss strain) of 20–28 gm. body-weight. Fifty-five animals were each given one subcutaneous dose of 0·5 mgm. diethylstilbœstrol in 0·05 ml. arachis oil daily for 6 days. On the second day after the treatment with diethylstilbœstrol ceased, the phagocytic activity of the reticulo-endothelial system was measured in five animals by the rate of disappearance of a known amount of specially prepared carbon from the circulating blood[2], the procedure used being that described previously[1], and the total body phagocytic activity or phagocytic index being denoted by the symbol *K*. On each successive day thereafter, up to the twelfth day, the phagocytic activity was measured in further groups of five animals.

Twenty-five of the animals were used as controls and were given 0·05 ml. arachis oil once daily for 6 days; the phagocytic activity was then measured on the eighth day by the carbon method referred to above. The arachis oil controls showed a phagocytic index or *K* value of 18 ± 5·8.

Table 1. DURATION OF STIMULATION OF PHAGOCYTIC ACTIVITY OF THE RETICULO-ENDOTHELIAL SYSTEM AFTER CESSATION OF TREATMENT WITH DIETHYLSTILBŒSTROL

Day after cessation of 6-day treatment with diethylstilbœstrol	Phagocytic index (*K* value)	Percentage change in body-weight
2nd	90 ± 10·8	−5
3rd	102 ± 13·1	−7
4th	56 ± 9·8	−3
5th	62 ± 11·5	+2
6th	55 ± 6·3	+5
7th	36 ± 4·7	+5
8th	34 ± 1 2	+10
9th	23 ± 1 4	+5
10th	24 ± 1·5	+10
11th	24 ± 2 7	+10
12th	22 ± 4·1	+9
Control values in 25 animals	18 ± 5·8	

The results are shown in Table 1. Compared with the controls it can be seen that after treatment with diethylstilbœstrol ceased the stimulative effect on the phagocytes persists for approximately one week, during which time it gradually diminishes. By the eighth–ninth day the phagocytic index or *K* value has returned to within normal control limits.

A corresponding change in the body-weight of the animals also occurs. It was reported previously[3] that when the daily dose of diethylstilbœstrol rises above 0·1 mgm. the animals lose weight. From Table 1 it can be seen that this loss in weight continues for about 4 days after the diethylstilbœstrol treatment has ceased and thereafter there is gain in body-weight.

In these investigations we gratefully acknowledge assistance from the Central Research Fund of the University of London and from the Medical Research Council.

HÆMATOLOGY

Observations on Globin, Hæmoglobin and Haptoglobin using a Rabbit Antiglobin Serum

AN antiserum against human globin was raised in a rabbit by immunization with globin prepared from adult hæmoglobin by the methods of Anson and Mirsky[1] and Jope, Jope and O'Brien[2]. A 1 per cent solution was injected subcutaneously in Freund's adjuvant[3], and intravenously. The resulting antiserum precipitated both human globin and human hæmoglobin; 1 ml. precipitated about 0·5 mgm. of hæmoglobin.

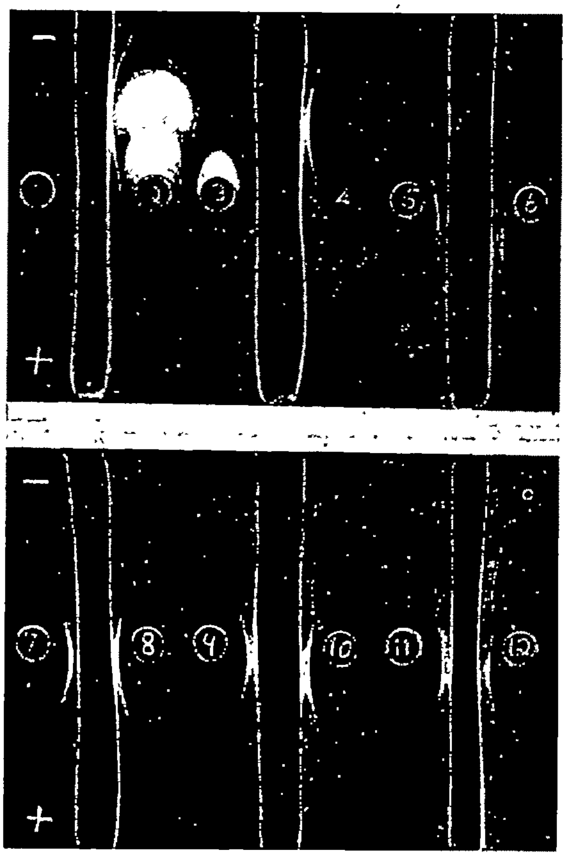

Fig. 1. Immunoelectrophoresis with antiglobin antiserum

A series of immuno-electrophoretic analyses in *p*H 7·0 0·05 *M* phosphate buffer in 0·8 per cent agar, using this antiserum, is shown in Fig. 1. The antigen cups are numbered. No. 1 contains human serum, which shows a faint precipitin line of a protein which has moved slightly towards the anode. This probably is haptoglobin-bound hæmoglobin. A 5 mgm./ml. solution of globin in 0·9 per cent sodium chloride was placed in cup 2. This shows a precipitin line due to protein which has moved towards the cathode, and in addition, a heavy precipitate of protein in the agar. A 1 mgm./ml. solution of globin in cup 3 shows a similar precipitate in the agar, but no immunological precipitate has occurred, presumably because of complete precipitation of the globin before it reached the antibody. The same concentration of hæmoglobin in cup 4 shows a precipitin line of similar electrophoretic mobility to the globin in cup 2.

The remaining analyses illustrate the effect of increasing the concentration of either globin or hæmoglobin in human serum. The same series of concentrations of both proteins was used, that is, 0·3, 0·6, 0·9 and 1·2 mgm. per 1 ml. of serum. The mixtures containing globin in cups, 5, 7, 9 and 11 and hæmoglobin in cups 6, 8, 10 and 12 are in order of increasing concentration.

All the hæmoglobin mixtures show a curved precipitin line of protein which has moved slightly towards the anode. In addition, at 10 and 12, there is a second arc of precipitation on the cathode side of the origin, the two arcs of precipitate forming a continuous line. Filter-paper electrophoresis of the mixtures in cups 6 and 8 showed the hæmoglobin

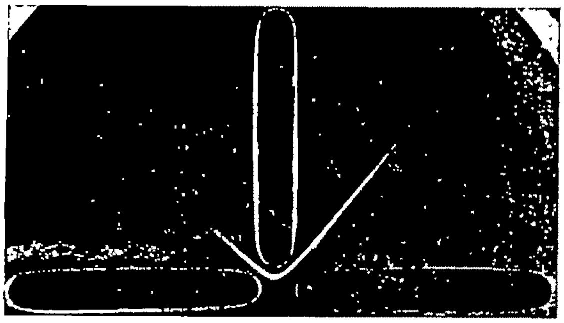

Fig. 2. Gel diffusion plate. Antiglobin antiserum in the vertical trough. Hæmoglobin in serum in the left-hand trough. Hæmoglobin in saline in the right-hand trough

to be entirely haptoglobin-bound, whereas those in cups 10 and 12 showed both haptoglobin-bound and also free hæmoglobin. The precipitin line on the anode side of the origin is therefore interpreted as indicating haptoglobin-bound hæmoglobin, that on the cathode side being free hæmoglobin, similar in mobility to that in cup 4. Similar double arcs of precipitate have been described by Boivin and Hartmann[4].

All the globin mixtures show an arc of precipitate of identical mobility to the haptoglobin-bound hæmoglobin, strongly suggesting that haptoglobin also binds globin. In addition, the higher concentrations of globin at 9 and 11 show precipitation on the cathode side of the origin similar to that shown by free globin in cups 2 and 3. If it is assumed that this precipitate is free globin, this would indicate that the globin-binding capacity of human serum haptoglobin is similar to its hæmoglobin-binding capacity.

Allison and Humphrey[5] deduced that when antigen and antibody at optimal proportions diffuse towards each other from troughs at right angles to each other in an agar gel, a straight line of precipitation is produced. The angle θ between the line and the antigen trough is related to the diffusion coefficients of the antigen (Dg) and antibody (Db) by the formula: $\tan\theta = (Dg/Db)^{1/2}$. They substantiated this by measurements of such angles produced by a series of antigens covering a wide range of molecular size, and their equivalent antisera. The antiserum against human globin enables us to measure such angles for free hæmoglobin, and for haptoglobin-bound hæmoglobin, that is for two proteins, antigenically identical, but of considerably different molecular size.

Fig. 2 is a photograph of such an agar plate, in which the antiserum was placed in the vertical trough, and hæmoglobin in identical concentrations, at optimal proportions to the antiserum, in the horizontal troughs. The hæmoglobin solution in the left-hand trough contained human serum at a concentration equivalent to 1 ml. per 0·5 mgm. of hæmoglobin. Filter-paper electrophoresis confirmed that all the hæmoglobin in this preparation was haptoglobin-bound. Straight lines of precipitation are obtained giving values of θ for free hæmoglobin of 51°, and for haptoglobin-bound hæmoglobin of 43°.

Assuming a diffusion coefficient of rabbit γ-globulin of $3{\cdot}8 \times 10^{-7}$ cm.^{2} sec.$^{-1}$, the diffusion coefficient of free hæmoglobin can be calculated as $5{\cdot}8 \times 10^{-7}$ (Gutter, Sober and Peterson[6] reported a value of $6{\cdot}0 \times 10^{-7}$ for carboxy-hæmoglobin). The diffusion coefficient of the complex is calculated as $3{\cdot}3 \times 10^{-7}$.

These results show that straight lines can be produced in this system when an antibody is treated at optimal proportions with its antigen at two widely different molecular sizes. The difference of molecular sizes is indicated by differences in the values of the angles θ.

Frequencies of the Haptoglobin Serum Groups among Blood Donors from Austria and Germany

THE frequency of the gene Hp^1 among the European populations so far tested have shown only a slight deviation of 40 per cent (Table 1). Samples from Austria and Germany have hitherto not been examined. For our studies we used sera of 201 blood donors from Münster, Westphalia (Germany), 273 blood donors from Bavaria (three districts of Upper Bavaria)[1], and sera of 621 blood donors from Vienna and environs (Austria).

Table 1

A modified technique of starch-gel electrophoresis[2,3] has been applied using polyvinyl chloride trays with 10 channels (internal dimensions: 25 cm. long, 1 cm. wide, 0·8 cm. deep) for electrophoresis. The hydrolysed starch was obtained by the Connaught Medical Research Laboratories, Toronto, prepared by Smithies' method. Three serum samples to which hæmoglobin was added amounting to 300 mgm. per cent were placed in each channel at a distance of about 7 cm. The sera were applied to filter paper, Schleicher and Schüll No. 5703. A borate buffer (pH 8·4) was used for the gel as for the electrode chambers. Electrophoresis was performed with the high-voltage apparatus described by Wieland and Pfleiderer[4]. The voltage gradient was kept at 9 V./cm. and 95 m.amp. for 20 channels during a period of 3½ hr. After electrophoresis the slides were stained with a benzidine or o-dianisidine reagent for peroxidase activity.

The frequency of the three haptoglobin types and the gene frequency of Hp^1 are shown in Table 2. No individual of the Hp 0–0 group has been detected. The frequencies of the three phenotypes are in good agreement with the genetical theory of Smithies and

Table 2

Fœtal Hæmoglobin in the Monkey

SOME well-known physico-chemical differences between human adult and fœtal hæmoglobin prompted us to find if similar differences exist between hæmoglobins from adult and new-born monkeys. The present communication describes the examination of the blood of 8 adult and 4 new-born monkeys (*Macacus rhesus* of North India) by the alkali resistance test and paper electrophoresis. Pregnant monkeys were obtained and were delivered in the cage to provide the new-born monkeys. Heart blood from the new-born and venous blood from the adult monkeys was collected in citrate solution. The alkali denaturation method of Singer *et al.*[1] was employed for determining the proportion of alkali-resistant hæmoglobin. Electrophoresis was carried out in 'Elphor' apparatus using paper strip No. 2043 *a* Mg 1 at 250 V. for a period of 16 hr. in veronal buffer of *p*H 8·6 and ionic strength 0·05.

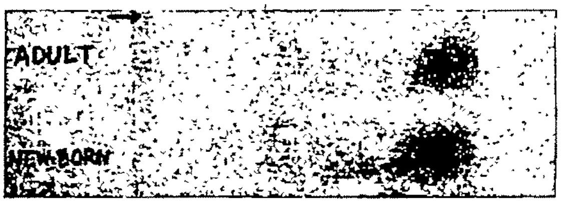

Fig. 1. Electrophoretic mobilities of hæmoglobin from adult and new-born monkeys

Fig. 1 shows the electrophoretic mobilities of hæmoglobin from adult and new-born monkeys. Hæmoglobins from both the adult and the new-born monkeys consist of one component only and have identical electrophoretic mobilities. Jacob and Tappen[2], however, obtained more than one component in a few of the other species of adult monkeys examined by them.

Table 1 shows the percentage of alkali-resistant hæmoglobin found by us. Adult monkeys contain 1·0–5·0 per cent alkali-resistant hæmoglobin, with an average of 2·9 per cent, whereas new-born monkeys contain 38·8–60·0 per cent, with an average of 48·9 per cent. Though the number of animals in the new-born group is rather small, the results are sufficiently indicative of the existence of a specific fœtal hæmoglobin characterized by resistance to alkali denaturation. In a recent communication, Beaven and Gratzer[3] have obtained evidence of a specific fœtal hæmoglobin by electrophoresis in agar gel. By using a moving-plate spectrograph, these workers have further shown that fœtal rhesus monkey hæmoglobin has the tryptophan fine-structure band at about 289·7 mμ, whereas the adult pigment has its band at 291·0 mμ—a condition very similar to that for fœtal and adult human hæmoglobins.

Characterization of the fœtal monkey hæmoglobin by its resistance to alkali denaturation, however, allows its easy detection by a relatively simple procedure. The quantities of fœtal hæmoglobin in the new-born monkeys have been measured at intervals of 15 days for 90 days in order to ascertain the time of disappearance of the fœtal pigment. Table 2 shows the percentage of fœtal hæmoglobin in the blood of these young animals. It was found that the amount of fœtal hæmoglobin is reduced to 1·4–

Table 1. PERCENTAGE OF ALKALI-RESISTANT HÆMOGLOBIN IN ADULT AND NEW-BORN MONKEYS

Animal No.	Adult Alkali-resistant hæmoglobin (per cent)	Animal No.	New-born Alkali-resistant hæmoglobin (per cent)
1	1·8	1	38 8
2	5 0	2	50·0
3	4 5	3	47 0
4	2 5	4	60 0
5	3·4	—	—
6	1 0	—	—
7	3 0	—	—
8	2 0	—	—
Mean	2·9	Mean	48·9
Range	1 0–5 0	Range	38·8–60 0

Table 2. PERCENTAGE OF ALKALI-RESISTANT HÆMOGLOBIN OF MONKEYS AT DIFFERENT DAYS AFTER BIRTH

Days	No. 1	No. 2	No. 3	No. 4*
0†	38·8	50·0	47·0	60·0
15	35·5	46·0	42·0	50·0
30	15·5	25·8	20·8	19·8

60	5·0	18·2	1·5	—
75	2·5	9·2	1·5	—
90	2·4	6·2	1·4	—

* Animal No. 4 died on the fortieth day.
† 0 day indicates just after birth.

6·2 per cent in the course of 60–90 days, with a variable rate of disappearance. For human new-born babies, though the amount of fœtal hæmoglobin varies between 30·0 and 85·0 per cent at birth[4], it gradually disappears, so that not more than 10·0 per cent is found after 4 months[5] and less than 1·0 per cent after the first few years of life[6].

The close similarity between monkey and human hæmoglobin reported here and elsewhere[3] indicates the need for further work using various parameters that characterize different hæmoglobin types.

Differences in Numbers of Erythrocytes between Inbred Lines of Chickens

No breed differences in numbers of red blood cells have been reported in poultry[1] although Lucas and Dennington[2] have shown small differences in hæmoglobin concentration and in the volume of packed red cells between inbred lines of the same breed (White Leghorns, as used in this work). In the results reported here, much more extensive differences in all three characters, which appear to represent a distinct form of variation, have been found.

Adult females of the Reaseheath inbred White Leghorn strains *C*, *I* and *W* were used[3]. All three lines have been brother–sister mated continuously for over 20 generations, but the attained level of inbreeding is probably well below the calculated figure, as segregation of genes for differences in red cell antigens is still occurring[4].

Egg production in the birds tested varied somewhat, but no differences could be detected between birds in lay and those out of production. The method of housing, too, differed in that some of the *C*-line and all the *I*-line birds (the blood from these birds was kindly supplied by Dr. D. G. Gilmour, School of Agriculture, Cambridge) were kept in semi-intensive pens, whereas the rest were housed in battery cages. Again, there were no differences due to method of housing.

The birds were bled from the brachial vein into heparin, approximately 2 ml. being removed for determining hæmoglobin content and packed cell volume. Red blood cell counts could be carried out only on birds of the *C* and *W* lines.

For the hæmoglobin estimation, the concentration of oxyhæmoglobin was read in a Spekker photodensitometer, human blood with a known concentration being employed as the standard. Packed cell volume was determined by the microhæmatocrit method, using a micro centrifuge at 12,000 r.p.m. for 5 min. For red cells counts the methyl violet stain of Natt and Herrick[5] was employed and counting carried out visually with the improved Neubauer hæmocytometer.

The results in Table 1 suggest that the differences in red cell characteristics between the inbred line *C* and the others are due to a reduction in the number of red blood cells in the *C* line. Determination of plasma volumes with the dye dilution technique using azovan blue showed no substantial line differences, and indicates that a real reduction in numbers of circulating red cells is involved.

Table 1. DIFFERENCES IN RED CELL CHARACTERS BETWEEN INBRED LINES

Line	*W*	*I*	*C*	6 and 15 (ref. 2)
Hæmoglobin concentration (gm./100 ml. blood)	10·3	9·9	7·2	9·86
S.E. of difference	0·35 N.S.	0·16*	0·35*	
Number of birds	39	10	39	155
Hæmatocrit (packed cell volume, per cent)	33·6	32·6	23·8	30·9
S.E. of difference	1·12 N.S.	0·77*	1·12*	
Number of birds	31	10	33	155
Number of red blood cells (millions/ml.)	3·06		2·30	3·03
S.E. of difference		0·09*		
Number of birds	11		12	155
Mean cell volume ($\mu c.$)	109·8		104·0	102·0
Mean cellular hæmoglobin ($\mu\mu gm.$)	33·7		31·4	33·1
Mean cellular hæmoglobin concentration (per cent)	30·7	30·3	30·3	32·3

* Significant at the 0·01 per cent level. N.S., not significant.

Examination of blood films failed to reveal any evidence of reticulocytosis or other cytological signs of anæmia in the *C*-line birds. The heart-rate (as determined with a Cossor electrocardiograph) of birds of the *C* line averages 333, a value not significantly different from that of 338 for the *W* line. Their mature body-weight (1·57 kgm.) is well below that of the *W* line (2·00 kgm.), but exceeds that of the *I* line (1·29), whereas egg production (over a 44-week period) of the *C* line is 134 eggs, compared with only 80 for *W*, and 86 for the *I* line.

Tests so far carried out show no relationship between the observed oligocythæmia in line *C* with any hæmoglobin abnormalities. Electrophoresis of hæmoglobin solutions from birds of the *C* and *W* lines reveal no differences in the concentrations or mobilities of the two components previously reported by Johnson and Dunlap[6] either on filter paper at pH 8·6 or on agar gel at pH 6·4.

Further examination of the hæmoglobins for differences in resistance to alkali denaturation proved equally negative. Evidently a situation comparable with the human hæmoglobinopathies is not responsible for the differences observed in our inbred lines of poultry. Differences were, however, observed in resistance of the erythrocytes to osmotic pressure. Cells from birds of line *C* begin to hæmolyse at

Table 2. Osmotic Resistance of Red Blood Cells

Line	Beginning of hæmolysis (sodium chloride, per cent)	End of hæmolysis (sodium chloride, per cent)
C	0·495–0·480	0·300–0·285
W	0·435–0·420	0·300–0 285
Values quoted by Sturkie (ref. 7)	between 0·47 and 0 40	0 28

higher concentrations of saline than do those of the *W* line.

Figures based on visual assessments of the beginning and end of hæmolysis are given in Table 2. The proportions of hæmoglobin in solution at different concentrations of saline were also estimated using a 'Unicam' spectrophotometer set at 540 mμ. Expressed as a percentage of the amount released by distilled water, these are shown in Fig. 1.

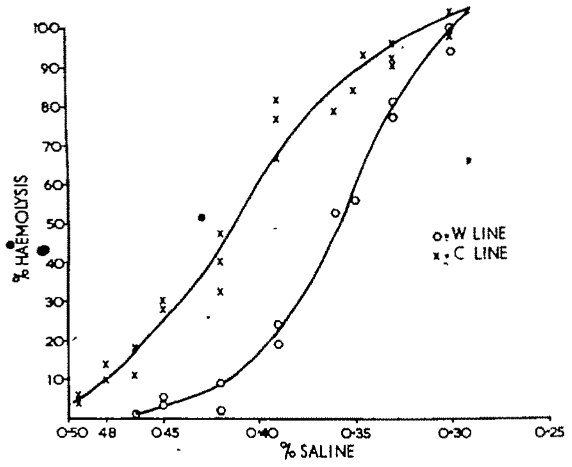

Fig. 1. Osmotic fragility curves

Diminished osmotic resistance is frequently indicative of lowered resistance to mechanical damage, leading to a reduction in the average life-span of the cells. This possibility is now under investigation as is the mode of inheritance of the condition.

PATHOLOGY

Alkaline Phosphatase in the Meninges and in Meningiomas

Little is known about the factors which influence cartilaginous and bony metaplasia in tumours apart from the presence of calcified debris and mucinous infiltration in the stroma of these tumours. Willis[1] discusses the association of frequent bony metaplasia in carcinomas of the large intestine, and suggests that this may be associated with the alkaline phosphatase content of these tumours. He furthermore suggests that studies of phosphatases and other enzymes should be undertaken in tumours which show a tendency to bony metaplasia. The presence of an alkaline phosphatase in the 'fibroblasts' of fibrous dysplasia[2,3] and in the so-called fibrocytes of ossifying fibromas[3] certainly lends support to the ossifying properties of this enzyme in certain tumours.

In view of the frequency of metaplastic bone formation in the dura mater, especially in the region of the falx cerebri and the high incidence of calcification and ossification in certain types of meningiomas, it was decided to investigate this problem with regard to its possible association with alkaline phosphatase.

For this purpose two meningiomas were investigated histochemically. Morphologically one was classified as a meningothelial and the other as a psammomatous type of meningioma. In addition, segments of the arachnoid and dura mater in the vicinity of the superior sagittal sinus were obtained from three different autopsies shortly after death and examined histochemically.

Alkaline phosphatase was demonstrated according to the methods described by Pearse[4]. A strong alkaline phosphatase was observed in the arachnoidal cap cells of the arachnoidal granulations and arachnoid membrane, and also in the arachnoidal cell nests in the substance of the dura and arachnoidal membranes. In the meningothelial meningioma a strong enzyme reaction was elicited by all the tumour cells and in the psammomatous type, the enzyme was localized to the cells around the psammoma bodies.

The finding of an alkaline phosphatase in the tumours and their cells of origin may offer some explanation for the frequency of metaplastic ossification in these sites. Of more importance, however, is that it supplies the pathologist with a method by which the relative proportions of arachnoidal cells and fibroblasts can be readily assessed in the tumours.

Details concerning these findings and further experimental work will be published elsewhere. This work was supported by a grant from the Council for Scientific and Industrial Research.

Isolation of a Cytopathogenic Agent from Skin Lesions of Cattle

Recently, we observed an outbreak of a disease in indigenous cattle at Gikongoro, Ruanda-Urundi, characterized by lesions on the teats and occasionally on other parts of the body and on the buccal mucosa. Material was obtained from nine cases, and with each sample transmission experiments were carried out in cattle. Following intradermal inoculation or scarification of the mucous membrane of the tongue, a definite reaction was noticed in five out of nine animals. This reaction was characterized by the development of necrotic lesions at the inoculation site, which showed some resemblance to those described in both natural and experimental cases of lumpy skin disease[1–3].

An excised nodule from an experimentally infected calf was used for the inoculation of monolayers of bovine testis cells. Some cytopathic changes were observed already at the first passage, but they were much more marked at the second passage, and consisted of intranuclear inclusions and the formation of large syncytia. The syncytia covered the whole monolayer in a few days and led to complete destruction of the cell sheet. Similar changes were observed in cultures of lamb testis cells. The time of appearance and the evolution depended upon the cell type and the age of the monolayer at the time of inoculation.

The tissue culture-passaged virus was inoculated intradermally into a one-month-old calf, which developed a necrotic lesion about 5 cm. in diameter at the site of inoculation. Rabbits and guinea pigs, inoculated by scarification of the skin with the tissue culture-passaged virus, showed a marked local reaction after a few days.

The agent we isolated shows characteristics somewhat intermediary between those of the Neethling and Allerton types of viruses recovered from cases of lumpy skin disease by Alexander *et al.*[2] in South Africa and by Prydie and Coackley[4] in Kenya. It produces cytopathic changes closely resembling those produced by the Allerton type, but the reactions observed in experimentally infected bovines are similar to those induced by the Neethling type. On the other hand, the clinical symptoms in the natural cases are milder and somewhat different from those commonly described in other African countries.

Further research is in progress and a detailed report of the experiments will be published elsewhere.

Induction of a Chorion-epitheliomatous Tumour in the Rat

CHORION-EPITHELIOMA of the uterus is a relatively rare tumour with many interesting features. It occurs only during or after pregnancy, and invasion and metastasis only take place *post-partum* or *post-abortum*. Spontaneous regressions occur in a small but significant number of cases[1]. It is the only known instance of naturally occurring tumour homograft[2]. A response to œstrogen therapy has been recorded[3] and remissions with folic acid antagonists have been reported[4].

The experimental induction of this tumour in laboratory animals would be of great interest. To our knowledge there are no records in the literature of spontaneous or induced chorion-epitheliomas in rodents, though Fischer and Kuehl[5] mention chorion-epitheliomatous structures in the ovaries of guinea pigs.

A tumour of the uterus in the pregnant rat has been induced in the following manner. A rat fœtus was removed after 2 weeks gestation by Cæsarean section, the placenta being left *in situ*. Benzpyrene powder was dusted into the gestational sac and the uterus then closed. After 4 months, vaginal bleeding was noted and exploratory laparotomy revealed the presence of enlarged cystic ovaries and thickened uterine horns containing hæmorrhagic fluid. Five months after the application of benzpyrene, a large tumour about 40 mm. × 30 mm. was palpated in the abdomen and the animal was killed. At autopsy a large, white, firm, nodular tumour measuring 60 mm. was seen in the uterine horn. There were numerous secondary deposits in the abdominal cavity. In the lungs there were pneumonic patches but no secondary deposits. Histologically, the tumour was a highly anaplastic growth having both sarcomatous and decidual elements. Many mitoses were present. This tumour was transplantable with a 100 per cent yield on subcutaneous passage and kills the host in 7–10 days.

The Ascheim–Zondek test was negative—but it was equally negative with urine from normal pregnant rats. Animals bearing intrauterine transplant tumours or very large subcutaneous growths have hæmorrhagic or lutein cysts in the ovary.

The action of folic acid antagonists on this tumour is being studied. Preliminary investigations have shown that it is sensitive to 'Methotrexate'[6] if the drug is given in high doses. An attempt is also being made to determine the sex of the tumour cells.

Twenty-five rats were similarly treated with benzpyrene and it appears that tumours are developing in two more animals.

A detailed report on this work will follow shortly.

I am indebted to Dr. S. S. Epstein for helpful discussion and criticism, and to Dr. C. P. Cherry for histological examinations.

Presence of Chicken Tumour Virus in the Sarcoma of the Adult Rat inoculated after Birth with Rous Sarcoma Tissue

THE heterotransplantation of Rous sarcoma to newborn rats results in lethal hæmorrhagic disease occurring in these animals[1–3]. Svet-Moldavsky[3] succeeded in determining the infectious virus in hæmorrhagic cysts, while Zilber and Kryukova[1] and Kryukova[4] had negative results. In our experiments, the virus was not found in every case, but we observed it in some of the animals[3,4]. Svet-Moldavsky[6] has also shown that Rous virus can induce the formation of rat sarcomas which do not contain the virus. On the basis of our material we came to a similar conclusion. In 2 out of 87 young rats inoculated 1–7 days after birth with a single dose of 0·3 ml. of cut fresh Rous sarcoma tissue diluted with physiological saline to make a 50 per cent suspension, large sarcomas were found in thigh muscle tissue in addition to hæmorrhagic cysts occurring in other parts of the body. The first case was observed 5 months and the second one 7 months following inoculation of Rous sarcoma; the cyst was localized in the axillary region, whereas the sarcoma grew in the thigh muscle of the hind leg.

Table 1. TESTS FOR THE PRESENCE OF AVIAN TUMOUR VIRUS IN THE WALL OF THE HÆMORRHAGIC CYST, IN BLOOD, SARCOMA AND ITS FIRST PASSAGE, MADE ON 20–29-DAY OLD CHICKENS

Material taken from the adult rat inoculated after birth with Rous sarcoma tissue

Inocula	Dose of 50 per cent tissue suspension in physiological saline (i.m.)	No. of chickens	No. of chickens dead from tumours
Cyst wall	0·8 ml.	3	1
Blood from the cyst	2·5 ml.*	2	0
Sarcoma	1 ml.	2	1
First passage of sarcoma in new-born rats. Removed on sixteenth day and irradiated with 5,000 r.	1 ml.	3	2

* Undiluted whole blood from the cyst.

In the case of the cyst, the presence of virus in the cyst walls, blood and tumour was shown after transfer of these tissues to chickens (see Table 1). In the case of the sarcoma, the blood remained ineffective, thus excluding the possibility of a mechanical transmission of the virus into the sarcoma. The virus was found to be present in the first passage of sarcoma made on newborn rats and taken on the sixteenth day after transplantation. Before transfer to chickens, the tumour tissue was killed by irradiation with 5,000 r. When tumours of the first passage were tested in chickens after 36 days, metastasizing sarcomas were also obtained (results not included in Table 1). In addition, Kryukova[9] found that after infection of rat *M*-1 sarcoma *in vivo* with Rous sarcoma virus, it was impossible to detect the virus after 6 hr. The *M*-1 sarcoma cells incubated with this virus when transferred into rats likewise induced tumours which do not, however, contain the virus. These findings emphasize that in our experiments an intimate association of virus with mammalian tumour cells took place which was promoted by infection of ontogenetically immature recipients.

All tumours obtained in chickens macroscopically and microscopically resembled the Rous sarcoma and contained a large amount of viscous intercellular ground-substance. Their growth was very similar to the growth of Rous sarcoma in non-tolerant[7] and tolerant[8] turkeys. At the site of implantation—in the pectoral region—distinct tumours were observed, but they never reached a large size, because the animals succumbed to a metastatic effusion localized largely in the lungs. The tumours were transferable to chickens both by means of tissue suspension and by extracts obtained through centrifugation at 13,000*g* for 15 min. However, after re-transplantation to newborn rats they did not grow.

All the findings provide evidence that the avian virus may participate directly in the formation of mammalian sarcomas and may be present there in an infectious form.

RADIOBIOLOGY

Effect of X-Rays on the Development of the Infective Larvæ of *Oesophagostomum radiatum* (Rud. 1803) (Strongylidae : Nematoda)

FOLLOWING a report by Jarrett *et al.*[1] on the stimulation of resistance in sheep to infestation with *Haemonchus contortus* by dosing with X-irradiated infective larvæ, investigations are being undertaken at this laboratory on the value of this technique in producing resistance in calves to gastro-intestinal helminths.

In a trial with *Oesophagostomum radiatum* in which calves five months old and reared worm-free were used, 4 animals were each given 7,000 normal infective larvæ and 10 others a similar number of infective larvæ exposed to 20,000 r. of X-radiation. The radiation was given in a single dose at 1,000 r. per min. on a 220-kV. 'Maximar' at 220 kV., no filter, H.V.L. = 0·4 mm. copper. Calves from the group given irradiated larvæ were killed and examined for worms 3, 4, 5, 6 and 8 weeks after infestation, and a calf from the control group 6 weeks after infestation.

Table 1. WORMS PRESENT IN CALVES GIVEN X-IRRADIATED (20,000 R). AND UNTREATED LARVÆ OF *Oesophagostomum radiatum*

Calf No.	Time after infestation (weeks)	Worms present			
		5th stage		4th stage	3rd stage
		♀	♂		
	X-irradiated group				
365	3	160		2,140	0
366	4	920	40	45	0
372	5	465	5	105	0
367	6	268	4	9	0
374	8	1,440	75	0	0
	Control group				
362	6	1,825	1,880	0	0

The results of these examinations are set out in Table 1. Although only one calf in the control group was examined, the proportion of male to female worms in this animal was in conformity with that found in calves used in earlier studies on infestations with untreated larvæ. The presence of fourth-stage larvæ in the calves killed at 4, 5 and 6 weeks is not considered to be a result of radiation, for numbers of this stage have been seen in calves given single doses of untreated larvæ and killed at comparable times. The main effect of this level of radiation therefore was to prevent the establishment of an adult male population in normal numbers.

The fæcal egg counts of the survivors of the control group followed the trend usually seen in experimental infestations, whereas the egg counts of the survivors of the group receiving treated larvæ remained at a low level or were negative. Female worms from the calves of the latter group killed at 5, 6 and 8 weeks contained eggs which appeared to be infertile, and afterwards it was found that most of the eggs in the fæces of the surviving calves of this group could be detected only by sedimentation, as they did not float in the salt solution used in the standard egg counting technique of Roberts and O'Sullivan[2]. No division of the cell had occurred, and the eggs did not develop in fæcal cultures.

In addition to the selective action on the larvæ destined to be males it is possible then that the level of X-radiation used also had a sterilizing effect on one or perhaps both sexes, as recorded by Schwartz[3] for larvæ of *Trichinella spiralis* exposed to X-rays.

Further details of this experiment will be published elsewhere.

Stimulating Effects of Nuclear Radiations on Development and Productivity of Rice Plants

In a report[1] which came to our notice in 1956, Kuzin showed the presence of the stimulating effects of ionizing radiations on the growth and development of several agricultural crops save rice. It was therefore felt desirable to study a possibility of obtaining an increase in development and productivity of rice crop through treatment with nuclear radiations.

Dry grains of rice varieties *C*33-18 and *D*17-88, the moisture contents of which had been stabilized in a room maintained at about 70 per cent relative humidity for 9 days, were exposed to 500 r., 1,000 r., and 1,500 r. of γ-rays from a 1,000-c. 'Theratron Junior' cobalt-60 teletherapy unit. Germination tests were conducted on moist filter papers in Petri dishes. The sprouts were transferred to nursery pots on the fifth day. When 30 days old, the seedlings were transplanted in unfertilized plots, each measuring 5 ft. by 33 ft. Plant heights and panicle lengths were taken just before harvest, followed by thorough gleaning to make up for the loss due to lodging. The results are summarized in Table 1.

Application of both tagged and untagged monoammonium dihydrogen orthophosphate, each in concentrations of 20 lb. phosphate/A., 40 lb. phosphates/A., and 60 lb. phosphate/A., to 6 plots of 39-day old transplants of rice variety *C*28-16 at the ground-level, was made on the ninth day after transplanting; the specific and total activities used being 175 μc./gm. total phosphate and 4554·82 μc., respectively. The results for plant height and grain yield are presented in Table 2.

Table 1. EFFECT OF γ-RAYS ON SEED GERMINATION, PLANT HEIGHT, PANICLE LENGTH AND GRAIN YIELD OF RICE VARIETIES *C*33-18 and *D*17-88 TESTED IN 1959

Variety	Treatment	Germination (per cent)	Average plant height (cm.)	Average panicle length (cm.)	Grain yield (kgm./A.)	Ratio to control (per cent)
*C*33-18	0 r.	95	129·5	22·2	1,260	100·0
	500 r.	94	134 6	22 5	1,320	104·8
	1,000 r.	96	141·8	22 9	1,371	108·8
	1,500 r.	94	131·8	22·6	1,464	116·2
*D*17-88	0 r.	100	125·3	29·1	1,160	100 0
	500 r.	100	125 4	28·9	1,285	110·8
	1,000 r.	100	129·0	29 8	1,219	105·1
	1,500 r.	100*	124 3	26·7	1,035	89·2

* Shortest plumule and longest radicle.

From Table 1 it appears that germination percentages of both control and irradiated seeds are the same in *D*17-88 and almost equal in *C*33-18. The yield response of *C*33-18 is positive and progressive at all three dosages, whereas that of *D*17-88 at 500 r. and 1,000 r. is positive, but regressive at the latter, and negative at 1,500 r. of γ-radiation. Over the range tested, dosages of 1,500 r. and 500 r. of γ-rays seem to be the best for the highest crop return of *C*33-18 and *D*17-88, respectively. Generally, no clear-cut differences in panicle length and plant height among the control and irradiated *D*17-88 are obtained. Apparently, there is some conspicuous difference only in plant height between control and irradiated *C*33-18, especially at the 1,000-r. level.

It is worth recording an observation that the number of plants lodged progressively increased from a very few at the 1,500 r. level to 100 per cent in the control in both varieties just before the maturity of grains. Irradiation treatment therefore seems to promote silicification of cell walls, that is to say, structural strength, through its favourable influence on utilization by rice plants of potassium and/or silicon from the soil. This point is being further studied.

Table 2 indicates that *C*28-16 yields considerably better and higher at all three levels of radioactive phosphate additions than at the corresponding levels of non-active phosphate applications. An increase in the yield of grain dropped by 16–17 per cent due probably to a relatively large total activity at the level of 60 lb. phosphorus-32 phosphate/A. A noticeable gain in stature over plants treated with phosphorus-31 is found among plants subjected to 748·36 μc. and 1517·92 μc. of phosphorus-32. Although phosphorus-32 has a short half-life of 14·30 days, and its activity in plant body and the soil is no longer readily detectable about 3–4 months after fertilization, it cannot as yet be recommended for practical applications in view of the serious problems of radiation protection and health hazards.

Table 2. EFFECT OF PHOSPHORUS-31 AND PHOSPHORUS-32 ON PLANT HEIGHT AND GRAIN YIELD OF RICE VARIETY *C*28-16 TESTED IN 1959

Treatment*	Total activity of ^{32}P† (μc.)	Average plant height (cm.)	Grain yield in lb. per 23 clusters	Increase (per cent)
0	—	64	0·40	—
20 lb. $^{31}P_2O_5$/A.	—	102	0·87	—
40 lb.	—	113	1·57	—
60 lb.	—	128	2·45	—
20 lb. $^{32}P_2O_5$/A.	748·36	114	1·27	46
40 lb.	1,517·92	123	2·27	45
60 lb.	2,288·54	127	3 16	29

* Applied 9 days after transplanting.
† Calibrated and supplied by Radiochemical Centre, Amersham, Bucks.

These results are clearly indicative of the stimulative effects of comparatively low levels of both β- and γ-rays on the growth and productivity of rice plants. The varietal difference in reaction to an equal dose of the same kind of nuclear radiation is observed. Future work is planned to test the stability or otherwise of these effects in the following season, and the overall interaction between γ-ray treatment of dry seeds over a wider range of doses, and the non-active or radioactive phosphate additions to be made later at various stages of plant growth from irradiated seeds of rice.

A Comparison of Iodine-124 and Iodine-131 Thyroid Dosimetry

THE purpose of this communication is to show that the approximate estimate given by Doniach and Francois[1] of the ratio R of the quantities (in mc.) of iodine-124 to iodine-131 required to give the same average dose (in rads) to rat thyroids has been modified by more exact calculations; further, to demonstrate the effect of some biological variables on this ratio; and to discuss the implications in treatment of human thyroid disease with radioactive iodine. There are two such implications. First, the average doses within the human thyroid can be calculated for iodine-124, within certain limits of error, because the maximum and minimum do not differ by more than about 3 : 1. For iodine-131, however, with β-particles of much shorter range, the extreme non-uniformity of dosage, varying from 10 : 1 to 100 : 1 in thyroid tumours[2,3], would appear to render such estimates of 'average dose' of limited use. Iodine-124 would therefore be a therapeutic tool of greater precision than iodine-131, both for the control of thyrotoxicosis and for thyroid carcinoma. The accurate prediction of the amount of isotope required to be administered, which is possible, but is not always thought necessary for iodine-131, would be more worth while for iodine-124.

The second implication arises from the possibility that a smaller 'average physical dose' of relatively uniformly distributed radiation is required to produce the same biological effect in the rat thyroid than a given 'average dose' from iodine-131. Doniach had previously found a gain factor F of about 5 : 1 in rats for X-rays relative to iodine-131, after allowance for the different duration of irradiation, both in the inhibition of thyroid hyperplasia and in the induction of thyroid tumours[4,5]. Such gain factors should be enhanced in the human thyroid. The ratio of the millicurie quantity of iodine-124 to that of iodine-131 required to produce a given biological effect in a thyroid gland is not simply the ratio R of the 'average' physical doses, but is R/F. The factor F will be greater than unity if uniform radiation is more effective than the same 'average dose' of non-uniformly distributed radiation. A more relevant value of F may now be derived from the experiment of Doniach and Francois[1], since this experiment compares the effect of the two internally administered isotopes in rats.

Values of R (between 1·0 and 1·7) have been discussed[6,7] for human thyroids but values of F have yet to be determined.

To Doniach and Francois's experimental finding[1] of $R/F = 1{\cdot}8$ ($\pm 0{\cdot}2$ standard deviation) in rats, we wish to add that the theoretical ratio is $R = 2{\cdot}29$, if the following assumptions are made. Variables are discussed below. The shape of the thyroid gland was assumed to be a pair of cylinders each 5 mm. long and 2 mm. in diameter, of total weight 31·4 mgm., with centres 5 mm. apart, except where otherwise stated. The biological half-life was taken as 100 hr. The cylindrical shape gives rise to computational problems, the solution of which will be described elsewhere[7]. Allowance was made for radiation not absorbed within the gland. The k-factor of iodine-124 was taken to be 7·0 (refs. 8–10). The proportion of iodine-126 present as a contaminant of the iodine-124 was assumed to be 0·22 : 1 (in mc.), so as to be consistent with the material used by Doniach and Francois. The nuclides iodine-123 and iodine-125, in the amounts which were present, would not affect these results. The dose at the centre of one spherical lobe due to the other lobe was estimated to be less than 1 per cent and so this effect was neglected.

The biological half-life affects these results as shown in Table 1.

Table 1

Biological half-life	R (iodine-124 mc./iodine-131 mc. to give equal average physical doses in rads—2 cylinders)
2·9 days	2·22
4·17 days	2·29
5 days	2·30
10 days	2·40
Infinite	2·44

The fact that the maximal uptake is not achieved instantaneously would only increase these ratios by about 2 per cent.

Variation in the shape of the organ will affect the ratio as shown in Table 2.

Table 2

Shape	R (biological $t_{1/2}$ 5 days)
Two cylinders as above (31 mgm.)	2·30
Two spheres (total 30 mgm.)	2·12
Single sphere (total 30 mgm.)	1·88

Variations in weight of the rat thyroid will affect the results. The values given in Table 3 have been calculated for a pair of spheres[11], since this model shows the magnitude of the variation with sufficient accuracy.

Table 3

Weight of pair of spheres	R (biological $t_{1/2}$ 5 days)
20 mgm.	2·21
25 mgm.	2·19
30 mgm.	2·12

It will be seen that the extent of these variations is not unduly large compared with other errors in such experiments.

It should be mentioned that the proportion of iodine-126 present affects the calculated ratio R. This factor is not, of course, a biological variable, and the proportion present in any specimen of iodine-124 can be determined. In Doniach and Francois's experiment, the accuracy of this determination was ±5 per cent, and the change in R resulting from a change in proportion of iodine-126 from 0·21 : 1 to 0·23 : 1

would be from $R = 2.32$ to $R = 2.26$. (Subsequent batches of iodine-124, produced by bombardment at 30 MeV. instead of 18 MeV., have contained much smaller proportions of iodine-126.)

The general conclusions are not affected by such variations as are likely to occur. In particular, the experimental ratio for R/F of 1.8 ± 0.2 (excluding the k-factor uncertainty) found by Doniach and Francois is lower than the calculated value of $R = 2.29$, but the difference is only about twice the standard deviation of the experimental results. This shows that the gain factor F must be between 1 and 1·4. Therefore if the better uniformity of dose distribution affects this result *per se*, then the effect is small compared with the known non-uniformity of concentration of iodine-131 in rat thyroids[12], which was 5 : 1 for individual follicles. However, these follicles are of the order of 0·05 mm. diameter so that the dose in rads is likely to vary by less than 2 : 1 even for iodine-131. Therefore the experimental value of F is not inconsistent with the dosage non-uniformity factor in rat thyroids. The results of the comparison of X-rays and iodine-131 referred to above[5] depend upon other factors, that is, dose-rate, duration of exposure, and lower iodine uptake and dosage at the periphery of the glands. They are likely to be less relevant than a comparison of two isotopes.

In human thyroid tumours, however, there are areas up to 5 mm. diameter with little or no uptake of iodine[6], so that here F may be much greater.

BIOLOGY

Are Macromolecules Required for Growth of Single Isolated Mammalian Cells ?

A few strains of mammalian cells have been grown from large inocula in a protein-free medium[1] ; but the multiplication of single isolated cells requires that the medium be supplemented with protein, usually supplied as whole or dialysed serum[2]. Recently, it has been shown that for HeLa cells the serum can be replaced by two purified proteins, fetuin and albumin[3]. However, the role of these proteins is obscure. The following experiments demonstrate that for one cell strain, at least, the role of serum is not to supply protein as such, but probably to act as a source of essential growth factors of low molecular weight.

Horse serum was dialysed aseptically on a shaker at 5° C. for 24 hr. against ½ vol. of Parker's chemically defined medium, *CMRL*-1066 (phenol red omitted)[4]. In some experiments several such 24-hr. dialyses were carried out on the same sample of serum. *L* cells (strain 929 *E*) were immediately plated in the dialysates, using a procedure described previously[5]. Fresh dialysate was used for feeding the cultures, after one and two weeks of incubation.

While in *CMRL*-1066 alone, the cells failed to undergo even a single division ; after incubation for five days in the dialysate most cells had grown into microcolonies. Cell multiplication continued until these colonies contained several thousand cells each. The plating efficiency was about the same as with 20 per cent serum (Table 1). Growth-rates were about the same in both media.

Table 1. Plating Efficiency of *L* Strain Cells in Media with and without Macromolecular Components

	Plating efficiency*		
	Exp. 1	Exp. 2	Exp. 3†
CMRL-1066 + 20 per cent whole horse serum	69	82	73
CMRL-1066 + 20 per cent dialysed horse serum	70	80	69
CMRL-1066	0	0	0
CMRL-1066 dialysed‡ against whole horse serum	65	70	73

* Percentage of 100 cells added to each Petri dish which formed macroscopic colonies.

† In experiment 3 the serum was subjected to two previous 24-hr. dialyses.

‡ Whole horse serum was dialysed against one-half volume of *CMRL*-1066 for 24 hr. at 5° C.

In the presence of serum the cells exhibited many cytoplasmic granules, were roughly polygonal in shape, and closely adherent. In striking contrast was their appearance in the dialysate. Here the cells contained relatively few granules, were extremely fusiform, and were seldom in contact with one another. This tendency for cells in the dialysate to separate from one another was also noted in attempts to adapt *L* cells to grow continuously from large inocula in *CMRL*-1066 alone. Possibly this behaviour may be characteristic of growth in a protein-free medium.

When the standard 24-hr. dialysis was repeated three times on the same sample of serum, the final dialysate gave as high a plating efficiency as the first (Table 1, Exp. 3). This result would be expected from the equivalence of whole and dialysed serum in supporting cell growth. However, the amount of active material at any time was small, since even a twofold dilution causes a marked (fivefold) drop in plating efficiency. Dialysates did not give the biuret reaction, indicating that the concentration of peptides, if present, was low.

These experiments demonstrate that serum as such is not required for the multiplication of single *L* cells. It is possible that dialysis against serum may adjust the concentrations of the constituents already present in *CMRL*-1066, but it is more likely that serum is supplying one or more essential dialysable growth factors not present in the synthetic medium.

Some batches of horse serum have failed to yield active dialysates. A possible reason for this is advanced in a paper by Eagle[6] which appeared as this communication was being written. His experiments show that cultures inoculated with 10^5 *L* cells per ml. failed to grow in a chemically defined medium separated by a 'Cellophane' membrane from dialysed serum unless proteolytic enzymes were added to the serum compartment. This suggests that growth factor(s) was released by breakdown of the serum proteins. Since proteolysis of serum varies with temperature and time of storage[6], neither of which was controlled in my experiments, such variation could explain my failure to obtain active dialysates in some instances. This hypothesis is being tested. If, indeed, proteolysis is responsible for the release of growth factor(s), then trace amounts released without added enzymes might allow growth of small numbers of isolated cells, but be inadequate to support the dense populations employed by Eagle.

Non-specific Tolerance of Graft and the Dissociation of Two Types of Immunity

PREVIOUS work with induced immunological tolerance of skin grafts presented evidence of a strict specificity of acquired tolerance. The 'non-specific' tolerance should be induced in ducks by injecting them with a mixture of bone marrow and spleen cells from 60 pooled donors[1]. This finding, as well as other observations of 'non-specific' tolerance[2] can be explained by the antigenic overlapping between individuals genetically related to a certain extent. However, it was shown that, when heterografts were tolerated, tolerance of heterografts from other individuals of the same species could be also obtained. In one instance, tolerance of a turkey homograft[3] was found in a turkey which tolerated two chicken heterografts.

In chickens that had been in embryonal parabiosis with turkeys, the tolerance of skin heterografts in postfœtal life is of a much lower degree than that observed in turkeys. We have therefore sought to find out whether these animals would be able to tolerate chicken homografts even though they did not tolerate, or only partially tolerated, the turkey heterografts. In seven chicken parabionts, skin heterografts transferred at 14 days of age never survived longer than 20 days after transplantation. However, in five chickens, homografts continued to be tolerated. On four of them feathers grew, and the first signs of their destruction (feathers falling off, minor necrosis) were observed 35–60 days after transplantation. The destruction proceeded slowly and the final destruction of homografts was very difficult to determine (Fig. 1).

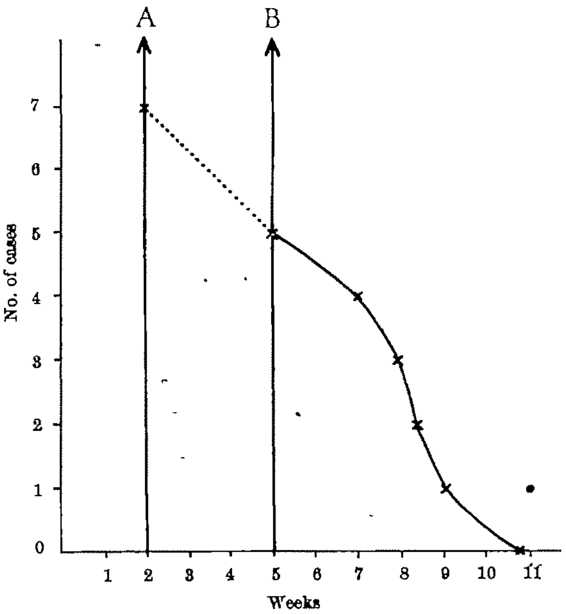

Fig. 1. Occurrence of the first signs of homograft destruction in parabiotic chickens with partial heterologous tolerance. *A*, Transplantation of skin at two weeks after hatching; *B*, the limit of maximal survival of homografts on control chickens and of heterografts on parabiotic chickens

It does not seem probable that the heterologous antigenic complex would involve the antigens which are necessary for the induction of homologous tolerance. Hašková (unpublished work) did not find that rat heterografts would induce immunity in *CBA* mice to skin homografts from *C* 57 and *A* strains of mice. Donors selected at random for homotransplantations in tolerant animals, and the persistence of homografts after the heterografts were sloughed, are inconsistent with the fact that individual specific antigens possessed in common by the two species might be involved in inducing this type of tolerance. It can be assumed that all heterologous cells were eliminated from the organism by the immune reaction and together with them all the sources of heterologous antigenic stimulus. The destruction of heterografts likewise shows that the animals are capable of immunological response. It seems, therefore, more probable that this non-specific immunological tolerance of homografts is due to a somewhat more complex mechanism. The heterologous antigenic complex induces in the embryo simultaneously and in even a higher degree the tolerance to homologous antigens which are not present.

In addition, the dissociation of two types of immunity has been found in tolerant animals, namely, transplantation immunity to skin grafts and antibody formation against erythrocytes, which is analogous to that found by Stark, O., Frenzl, B., and Křen, O. (personal communication) in homologous relationships in chickens. In turkey parabionts with a chick, the chicken heterografts are frequently tolerated for several months. In Fig. 2 one such case is included; the chicken graft tolerated by the turkey had been transferred to it 14 days after birth. The interspecies blood mosaicism disappeared from the turkey's circulation within two weeks after hatching. Between the eighth and twelfth week after hatching, immunization of animals with chicken blood was produced and around the graft repeated local applications were made of a large amount of turkey antiserum against chicken blood. The skin graft from the partner survived in spite of the fact that the recipient produced agglutinins against chicken erythrocytes of

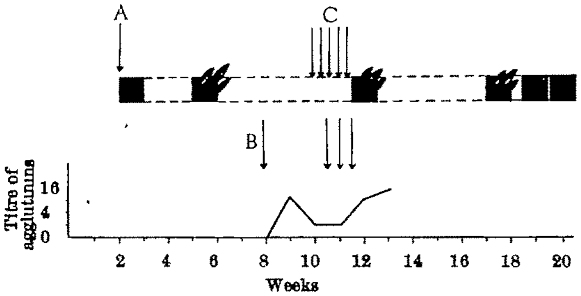

Fig. 2. Behaviour of a heterograft and formation of hetero-agglutinins in a parabiotic turkey. *A*, Transplantation of chicken skin from the partner to a parabiotic turkey; *B*, immunization with chicken blood; *C*, passive transfer of antiserum

the partner after starting with immunization. The first signs of destruction of the graft occurred seven weeks after the immunization had ended.

It may be possible that the formation of agglutinin and transplantation immunity are induced by different antigens; however, it seems more probable that the identical antigen releases two different types of immune mechanism. This difference may be due to binding the antigen with other substances which have no antigenic determinants, but do affect the further fate of the antigenic stimulus. Moreover, it appears that in heterologous relationships, the circulating antibodies do not disturb the tolerance of skin grafts, and the repeated local application of large amounts of heterologous serum (28 ml. within 9 days, the titre being 1 : 32) obtained by blood immunization fails to result in graft destruction. As in the case of a homograft[4], the serum antibodies do not induce the destruction of a tolerated graft.

Retarded Development of *Ostertagia* Species in Sheep

SOMMERVILLE[1,2] has indicated that the immature stages of *Ostertagia* species in sheep may remain dormant or slowly developing over a considerable period within the abomasal pits and glands. The factors controlling this delayed development have not yet been elucidated.

Experiments have been carried out to determine whether the size of a single infesting dose will influence the percentage of larvæ remaining in a partially developed state. Young sheep that had been raised 'worm-free' (excepting for *Strongyloides* species) were used. They received by a flank injection into the rumen either 1,000 or 100,000 infective larvæ. Autopsy was carried out 14 days later and a peptic digestion technique was used to ensure complete recovery of larvæ within the abomasal mucosa. The length was measured of at least 200 or 400 developing worms at the low and high dose-level respectively.

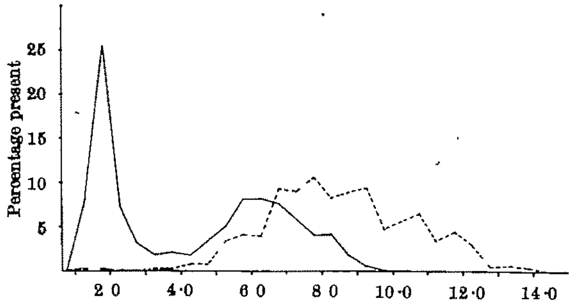

Fig. 1. Composite frequency polygon of size-distributions within the two groups of sheep. All sheep killed at 14 days. ----, larval dose 1,000; ——, larval dose, 100,000

At the higher dose-level a clearly bimodal size distribution appeared in each of the three lambs in this group. Of the developing larval worms 35–75 per cent were only 1–2 mm. in length; relatively few were 3–5 mm. and the remainder were grouped within and around the 5–8 mm. range, as seen in the accompanying composite frequency polygon prepared by combining the data from within each group of sheep (Fig. 1). Accurate mean, modal or median points cannot be obtained from these measurements because data from male and female worms were combined and the modal point for each sex is different.

At the lower dosage-level less than 2 per cent of developing worms were retarded in their growth, the great majority giving a more or less normal distribution around the 6–11 mm. size range.

Two features became apparent from these results, as shown in Table 1 and Fig. 1. At the higher dose-level a significantly greater ($P < 0 01$) percentage of larvæ had not attained 4 mm. in length in 14 days than at the low dosage-level. It appeared that the 'retarded' larvæ had failed to recommence growth following the third moult within the abomasal mucosa. This group consisted entirely of very small fourth-stage larvæ. Secondly, those larvæ at the higher dose-level that had developed beyond the 1–2 mm. size had still failed to attain the length achieved by the worms resulting from the low-level dose.

In the same experiment two additional sheep were given 100,000 larvæ and similarly autopsied at 56 days. It can be seen from Table 1 that although the total number of worms recovered at 56 days was similar to that recovered at 14 days, there was a great reduction in the proportion less than 4 mm. in length. It appears that retardation is not necessarily permanent and that growth and development may commence after a variable period of time. The limited data available also appear to support the suggestion that once growth has recommenced in the

Table 1

Sheep No.	Dose of larvæ	Days to autopsy	Dose recovered at autopsy (per cent)	Recovered larvæ less than 4 mm. (per cent)
C921	1,000	14	94·6	1·9
C939	1,000	14	92·6	1 1
C926	1,000	14	100 0	1 6
C930	100,000	14	56·7	35 9
C949	100,000	14	27·1	75·8
C944	100,000	14	32 4	59·1
C928	100,000	56	29·9	21·5
C927	100,000	56	27 2	19 6

retarded larvæ they develop rapidly to reach the same length as the others which showed a 'normal' development. It is noteworthy, however, that even at 56 days members of the high-dose populations had not reached the size of the worms in the low-dose populations, and had not, in fact, achieved the normal size quoted for *Ostertagia circumcincta*, the predominant member of the genus in the population. Despite their small size these worms appeared morphologically to be sexually mature and eggs were visible within the uteri of the females. Only relatively low and erratic egg counts (rarely more than 1,000 eggs per gram) were observed in these sheep, despite their heavy worm burden.

This work was carried out while I was the holder of the George Aitken Pastoral Research Scholarship.

Boron Deficiency in *Grevillea robusta*

Grevillea robusta A. Cunn. is used as a shade tree in many tea plantations in Kenya. It is easily established, and is little subject to pests or diseases. In December 1959 it was reported that *Grevillea* were dying on the whole of one field in a tea plantation in the Nandi Hills district of Kenya. The trees were 2–3 years of age and were dying back from the tip. Of many, only the main branches near the apex of the tree were affected, while one or two lateral branches lower down the tree carried healthy leaves. The more seriously affected trees were almost completely defoliated; but leaves could in many cases be seen sprouting from the main trunk at heights of 4 ft. down to ground-level. In almost all trees showing advanced symptoms there was cracking of the bark and exudation of gum. The symptoms are similar to those described by Vail *et al.*[1] for boron deficiency in wattle. The fact that, prior to the planting of tea and trees of *Grevillea* in the area in question, an attempt to establish wattle had failed, led to an investigation into the boron status of the soil and of the *Grevillea* trees.

Leaf samples were taken from two dead trees, some apparently healthy trees in the same field, and some healthy trees about two miles away from the affected field. Boron analyses on these samples showed one healthy leaf to have the highest boron content (17 p.p.m.) and one from a diseased tree to have the least (13 p.p.m.); the results of further leaf analyses were somewhat inconsistent. The figures for water-soluble boron in the soil, however, supported the idea that boron deficiency was in fact responsible for the effects. Table 1 summarizes the relevant results.

Soil samples taken at a depth of 18–24 in. from a healthy area in the Kericho district some sixty miles to the south of Nandi Hills had a water-soluble boron content of 0·13 p.p.m.

Table 1. WATER-SOLUBLE BORON (P.P.M. OF DRY SOIL)

	0–9 in.	9–18 in.	18–27 in.	27–36 in.
Soil from affected area	0·13	0·07	0·03	0·03
Soil from healthy area	0·20	0·17	0·14	0·06

Treatment by applications of borax to the affected area is being tried and an investigation into the boron contents of soil in other parts of East Africa is proceeding. A fuller report will be published elsewhere.

It may be noted that tea bushes showed no symptoms, which may be due to their lower boron requirement[2], or more probably to the effectual 'scavenging' operations of the extensive tea root system.

My thanks are due to the Board of Management and the Director of the Tea Research Institute of East Africa for permission to publish this communication.

Effects of *Gibberella fujikuroi* on Fungal Root-infections of *Pinus*

In connexion with several communications in *Nature*[1–4] concerned with the effects of gibberellins on the nodulation of legumes, it would seem opportune to put on record the following experimental observations relating to the influence of *Gibberella fujikuroi* on certain other root associations.

The test plants were seedlings of *Pinus sylvestris* growing in pot-cultures with three different soils, namely, two podsols (pH 5) contrasting as regards their mycological contents, and a soil of the agricultural type (pH 6·8). *Gibberella* was inoculated into the soils at sowing, and re-inoculated twice at monthly intervals. Three months from sowing, the inoculated cultures started to exhibit a slight depression in development. The figures in Table 1 give the average heights of seedlings five months old.

Table 1

	Podsol *A* (cm.)	Podsol *B* (cm.)	Agricultural soil (cm.)
Plants from control cultures	6·0	5·2	4·9
Plants from inoculated cultures	5·7	4·4	4·4

The decrease in vigour and height of the treated seedlings was accompanied by a noticeable shift in the proportion of the various root-associations affecting the plants. In podsol *A* which, in the control cultures, showed about an equal amount of normal and subnormal mycorrhizas, the presence of *Gibberella* stimulated the formation of the subnormal type of association at the cost of normal mycorrhizas. Decrease in the incidence of true mycorrhizal infection and simultaneous spread of a parasitic association (formed by *Rhizoctonia sylvestris*) was observed for the seedlings in podsol *B* inoculated with *Gibberella*. The 'treated' cultures in the agricultural soil exhibited a marked increase in numbers of a harmful (haustorial) infection and considerable suppression of mycorrhizas.

In older seedlings, about 8 months old, the slight growth differences between controls and inoculated cultures had disappeared, and examination of the root systems revealed a less pronounced contrast in incidence of mycorrhizal and non-mycorrhizal associations. These findings agree, at least in some respects, with observations by Mes[4] on the effect of gibberellic acid which, when applied to *Vicia villosa* in the very early stages of growth, was recorded to decrease nodulation, but had little or no influence on nodule formation in older plants.

Mixed cultures on a nutrient agar medium (for composition of this medium cf. Levisohn[5]), showed antagonistic effects of *Gibberella* on several mycorrhiza-formers tested, for example, the basidiomycetes *Boletus granulatus*, *B. scaber*, and *Rhizopogon luteolus*, and also on the parasitic mycelium *Rhizoctonia sylvestris*. In this connexion it should be mentioned that gibberellic acid incorporated in the above medium (before sterilization) at a concentration of 100 p.p.m. affected the growth-rate of the mycorrhizal fungi adversely. Colony diameters after 4 weeks growth are given in Table 2. *Rhizoctonia sylvestris* showed a profuse development of sclerotia in the presence of gibberellic acid.

Table 2

	Control medium (cm.)	+ 100 p.p.m. gibberellic acid (cm.)
Boletus granulatus	4	2
B. scaber	15	10
Rhizopogon luteolus	11	6

Detailed observations relating to the effects in soil cultures and nutrient media of *Gibberella* and gibberellic acid will be published elsewhere.

Sex Ratio of Ammocœtes

IN a previous communication[1], it was suggested that variations in the sex ratio of adult brook lampreys (*L. planeri*) might be due to the effect of environmental factors on the course of differentiation in the so-called hermaphrodite gonad of the ammocœte larva. As a result of the examination of a very large number of ammocœte gonads (Table 1), this view is now considered to be untenable.

The material used for this work consisted of ammocœtes of *L. planeri* from the River Yeo (north Somerset); mixed collections of *L. planeri* and *L. fluviatilis* from the middle reaches of the River Usk and from the River Teifi a few miles above the estuary; and specimens of *P. marinus*, the land-locked sea lamprey of the Great Lakes from the Oqueoc River, Michigan.

In *L. planeri*, and probably also in *L. fluviatilis*, differentiation of the gonads is, in a majority of ammocœtes, completed towards the end of the second summer of larval life at lengths of 50–60 mm. In *P. marinus*, on the other hand, recognition of the definitive ovary or testis is not possible in all cases at lengths less than 90 mm. The figures in Table 1 refer, therefore, in the case of *L. planeri* and *L. fluviatilis*, to animals more than 60 mm. in length and for *P. marinus* to those more than 90 mm. Even so there remains a number of animals in which differentiation of the gonad is not complete. In some cases, these transitional gonads are smaller than the definitive ovary and contain both auxocytes and follicles of undifferentiated germ cells; the remainder consists of apparent ovaries in which degenerative changes are occurring involving the disintegration of oocytes and the development of a pronounced connective tissue stroma in the medullary part of the gonad. A close study of sex differentiation in the ammocœte has convinced me that both these transitional gonad types are to be regarded as eventual testes.

Table 1

	Total	♀	♂	Transitional gonads	Ovaries per cent all gonads
L. planeri (River Yeo)	281	162	94	25	57·7
L. fluviatilis and *L. planeri*					
(River Teifi)	49	25	24	—	51·0
(River Usk)	61	34	18	14	55·7
P. marinus	72	37	30	5	51·4

In none of the groups of animals examined is the number of males greater than the females, even when all those with indeterminate gonads are counted as males. In the large group of brook lamprey ammocœtes there is a small but significant excess of females (57·7 per cent) and this is also true of the material from the River Usk. In *P. marinus* ammocœtes, and in those from the River Teifi, the sex ratio does not differ significantly from equality.

Reports on the sex ratio of adult brook lampreys have almost invariably indicated some excess of males over females, although individual estimates[2-7] have varied widely from near equality to as much as 5 : 1. In a survey of the spawning population of the River Yeo, carried out during 1947–60, I have found an overall sex ratio of 2·05 ♀ : 1 ♂ for a total of 1,492 animals, with annual variations from 1·2 to 3·4. Observations by Applegate[8] on spawning runs of the sea-lamprey in the Oqueoc River have also shown an excess of males, and of the 24,643 animals examined in 1949 only 31·8 per cent were females. Thus the available evidence, both for *L. planeri* and *P. marinus*, points to an approximately equal sex ratio in the larval stage and a definite but variable excess of males in the adult spawning population. It must therefore be concluded that the female suffers a much higher mortality than the male at some stage in the life-cycle between metamorphosis and spawning, while the variations which have been observed within the same population indicate that the factors which are responsible for this increased female mortality must operate with varying intensity at different times and in different localities. Since a similar situation obtains in both parasitic and non-parasitic lampreys it is possible that this increased female mortality may operate during, or shortly after, the critical period when metamorphosis is taking place.

I wish to thank Dr. V. C. Applegate of the U.S. Department of the Interior, Fish and Wildlife

Service for his co-operation in supplying ammocœtes of *P. marinus*.

Caretta kempi Garman on Welsh Coast

On January 3, a Mexican or Kemp's loggerhead turtle, *Caretta kempi* Garman, was found at high-water mark on Kenfig Dunes in Glamorgan. It was dead, but the body was in a good state of preservation, though the shields of the carapace were mostly missing. The weight was 2,420 gm., the carapace being 244 mm. long and 224 mm. at its maximum width; the length of the plastron was 199 mm. Two other specimens of this species, one slightly larger and one slightly smaller, are in the collection of this Department, both taken alive; one near Freshwater West on the Pembrokeshire coast, in December 1930, the other at Mochras Island at the north end of Cardigan Bay, in November of the same year.

In December 1938, an example of the other species of loggerhead recorded from Britain, *Caretta caretta* (Linn.), was stranded near Tenby; while in February 1946 one weighing 8,180 gm. was found alive on the beach at Oxwich, Glamorgan, and is now in our collections.

Whereas *Caretta caretta* appears to have a fairly wide distribution in tropical and sub-tropical waters on both sides of the Atlantic (though the breeding grounds are on the American side), the natural habitat of the smaller *Caretta kempi* is stated to be restricted to the Gulf of Mexico and adjacent waters, and it is less likely to be carried to the British coasts. About twenty British occurrences of the former, as compared with ten of the latter species, have been recorded[1].

Deraniyagala[2] suggested that the presence of loggerheads in European waters was probably due mainly or entirely to currents, and that they might be of importance as current-indicators; and Parker[3], discussing turtle strandings in 1938 on British coasts, considered it "difficult not to associate their coming with the remarkably warm weather and almost uninterrupted series of south-westerly gales which characterized late November and early December. It seems probable that there has been a strong indrift of warm surface water into the English Channel from the south-west". Russell[4] suggested another possible explanation—the general extension in recent times of warm water farther towards the Arctic, with a resultant northward extension of the boundaries of certain animals. He instanced the capture of a flying fish, *Cypsilurus heterurus*, in Oslo harbour in 1937; and it may be noted also that a *Caretta caretta* was found stranded on the Norwegian coast in December 1951[5]. No loggerhead had ever before been recorded from Scandinavian waters nor from the area east and north of Shetland.

From information supplied by Mr. H. H. Lamb of the Meteorological Office, it would not appear that the warm summer of 1959 over Britain and Europe had any connexion with the present occurrence of *C. kempi* on the Welsh coast. In fact the western two-thirds of the North Atlantic were colder in 1959 than for many years past, only the Bay of Biscay, the North Sea and waters east of about 20° W. being slightly warmer than average. It seems much more likely to be associated with some anomaly of the prevailing water currents. Over the north-eastern Atlantic, especially the waters around the British Isles and farther north, there was a remarkable prevalence of southerly winds in the autumn of 1959. The autumn and early winter, including December, were also notable for the repeated occurrence of a great sweep of west to north-west winds across the whole width of the Atlantic fanning cold water eastwards towards the Bay of Biscay; and this might possibly have produced a flow of water from the Bay of Biscay northwards to the shores of Britain.

Note added in proof. Since the above was written, I have been informed that the British Museum (Natural History) received a specimen of *Caretta caretta* found alive at South Uist on January 8 this year.

Elminius modestus Darwin in South-West Scotland

The present status of *Elminius modestus* Darwin in the British Isles has recently been summarized by Crisp and Southward[1]. They state that in 1958–59 "it is still relatively rare in Luce Bay and has not yet passed the Mull of Galloway. Similarly, there has been little change in the isolated and sparse colony in Lough [Loch] Ryan at the entrance to the Clyde Sea". In an earlier publication, Crisp[2] states that this Stranraer population, although dwindling in numbers, has persisted since 1950 and consists largely of old animals with corroded shells. According to his classification of abundance, rare is taken as "less than 1/m.^{2}; only a few isolated specimens in 1 hour's search" and occasional as "1–100/m.^{2}; often local and needing to be searched for; rarely close enough to breed".

Over a number of years we have been making an annual survey of the density of settlement of barnacles in the Clyde sea area and our observations on the present status of *Elminius modestus* in south-west Scotland are not entirely in agreement with those quoted above. The following results refer to early August 1959.

Elminius modestus is unevenly distributed in Luce Bay, possibly because of variations in local hydrographical conditions caused by a curious development of shingle spits. Nevertheless, it is readily found in many places, being most common on the western shore; for example, on an artificial structure running across the beach near Sandhead adults at a density of 1/cm.^{2}, young at 8–10/cm.^{2} and spat at 5–10/cm.^{2} were recorded. On parts of the shore at Drummore the species is common with individuals up to 2/cm.^{2}. Furthermore, the species has passed the Mull of Galloway since it was found at Port Logan on the open coast; although not common here, small groups were near enough for breeding if they reached maturity; large adults were not found.

There are at least two well-developed populations in Loch Ryan, with scattered individuals elsewhere on the shores. On the western side near Kirkcolm, *Elminius modestus* is abundant on artificial structures where weeds are infrequent. All size groups from fully grown adults to spat were recorded and in some 'cleared' areas cover is complete. On the town pier at Stranraer, although much less common than at Kirkcolm, all size groups are present and spat was settling in the late autumn. Scattered individuals are present on the railway pier. Larvæ were common in the summer plankton.

A full account of this work will be published elsewhere.

Multiple Infections of Trematodes in a Snail

IN an investigation of the incidence of various larval trematodes in the estuarine snail *Valacumantus* (*Pyrazus*) *australis*, results have been obtained showing that two species of trematodes tend to occur together in individual snails surprisingly often. To my knowledge an observation of this kind has not been recorded before. Cort *et al.*[1] studied the incidence of various larval trematodes in the snail *Stagnicola emarginata angulata*, and from an analysis of more than 7,000 dissections concluded that, in certain instances, there must be an immunity produced by the penetration of one species of trematode which prevents penetration of the same snail by a second species; or that there is an antagonism present which prevents the development of one when the other is present. In other instances of multiple infection they concluded that there was no evidence of any immunity or antagonism. In view of their findings the present results are noteworthy.

Results from an examination of 1,146 snails from Narrabeen Lake, near Sydney, is tabulated below:

	No.	Per cent
Stictodora spp. (Heterophyidae)	269	23 5
Austrobilharzia terrigalensis (Schistosomatidae)	52	4·5
Stictodora/*Austrobilharzia* (multiple infections)	39	3·4
Immature and unidentified infections	16	1·4
Other infections (Echinostomatidae and Philopthalmidae)	169	14·8
Total infected	545	47·6

Several postulates are possible to explain the unexpectedly high incidence of multiple infections of heteropyids and schistosomes. They need not be mutually exclusive: (1) a snail infected with the schistosome is predisposed to infection with the heterophyid; (2) a snail infected with the heterophyid is predisposed to infection with the schistosome; and (3) when the two kinds of eggs occur in the same bird evacuation, which happens to be in close proximity to a suitable snail, infection with the heterophyid and the schistosome occurs simultaneously.

GENETICS

Apparent Double Crossing-Over in a Short Genetic Interval in *Drosophila melanogaster*

IN view of the reported occurrence of double crossing-over within a short genetic interval in *Aspergillus*[1] and of the purported existence of negative interference in bacteriophage[2], it is worth while to record the recovery in *Drosophila melanogaster* of apparent double cross-over types within a short genetic interval where interference is nominally expected to be complete. These double cross-overs were found incidentally to a study of pseudo-allelism at the white (*w*) loci[3]. The relevant genetic interval extends from the *X*-chromosome loci of yellow body colour (*y*) to split bristles (*spl*), mutants of which served as markers for the study of crossing-over between *w* pseudoalleles. The standard map distance for this interval is commonly given as three units, a value at least twice as great as more recent measurements indicate[4]. Throughout this study, parental females were always made heterozygous for the autosomal inversions *Cy* and Ubx^{130}. These inversions serve to increase crossing-over strikingly in the *y*-*spl* interval to values varying from 5 to 11 units[5].

In Table 1 the variety of crosses and detected double cross-overs are listed. Most exceptional individuals were found among the progeny of females heterozygous either for y^2 *su*-w^a w^a *spl* (*su*-w^a= suppressor of w^a; w^a=whiteapricot eye colour) or *y ac* w^{ch} *spl* (*ac*=acheate bristles; w^{ch}=white-cherry eye colour) since these *w* mutants were used as testers in studying pseudoallelism. No concerted effort was made to recover double cross-overs; rather those tabulated here represent individuals, mostly males, which were easily and effortlessly identified through their distinctive phenotype. At best, therefore, the frequencies noted in Table 1 are minimal. The exceptions are deemed to be double cross-overs because genotypically they represent the expected contrary double cross-over classes: w^a or w^{ch} with none of the marker genes, and the allelic or pseudoallelic mutant with all the markers. Where the former were recovered their genotype was confirmed as follows. The w^a exceptions were tested for suppression by *su*-w^a. This is a critical test since this suppressor's action is delimited to the w^a mutant[3]. Since w^{ch} does not show dosage compensation, this property was employed for its identification. Where the latter class of exceptions was detected, the distinguishing phenotypic effects characterizing the

Table 1. RECOVERED APPARENT DOUBLE CROSS-OVER WITHIN THE *y*-*spl* INTERVAL AMONG THE PROGENY OF ♀♀ HETEROZYGOUS FOR INDEPENDENT *w* MUTANTS.

(15)	*y ac* w^{ch} *spl*/sp^2-*w*	♀ *y ac* sp^2-*w spl*/*y w spl* sn^3	92,400
(16)	*y* $w^{a4}B$ *spl*/w^a	♂ $w^{a4}B$	79,430
(17)	y^2 *su*-w^a w^a *spl*/w^{aM}	♂ w^a	93,670

w mutant served, in most instances, to verify its genotype. For example, the mutants w^{col}, w^{sat} and sp^{1}-w have such distinctive phenotypes and are mutationally so rare in occurrence that their recovery in association with all marker genes is best accounted for in terms of a double cross-over occurring on each side of the w loci.

Since the results do not represent a quantitative recovery of double cross-overs, there is little point in indulging in computations of the degree of interference. What these results do demonstrate is that, for a comparative short genetic distance, interference is not necessarily complete and double cross-overs do infrequently occur.

Thread Protein and β-Globulin Polymorphism in the Serum Proteins of Pigs

THREAD proteins, reported to be polymorphic in the sera of cattle[1], have now been demonstrated in serum samples from pigs, dogs, and horses. Thread protein polymorphism has been found in the pig also, but not in the relatively few samples from dogs and horses examined up to the present.

Pig thread proteins are readily seen in one-dimensional starch-gel electropherograms using the same pH 7·6 phosphate buffer and procedure described for cattle sera[2]. The zones are very narrow, indeed thread-like, in suitable gels. However, the zones may be faint, or not appear at all if the nature of the gel deviates only a little from the optimum. No difficulty has been experienced in detecting thread proteins in gels prepared from several batches of Hopkin and Williams potato starch after suitable acid hydrolysis[2]; but it has not been possible to detect thread proteins, particularly in cattle sera, using a commercially available starch hydrolysed ready for starch-gel electrophoresis.

Three thread-protein phenotypes have been found in sera from Large White and Essex Saddleback pigs, depending on the presence of one or both of a pair of thread proteins. The three phenotypes are shown in Fig. 1, after two-dimensional electrophoresis, first in agar then in starch gel. Sera of the three phenotypes were resolved initially in 1 per cent agar using pH 8·4 borate buffer (4·65 gm. boric acid in water adjusted with sodium hydroxide and diluted to 1 l.). Afterwards 0·5 cm. wide length-wise strips of agar containing the resolved albumin zone were cut from each of the three agar gels and inserted side-by-side across a previously prepared starch gel of suitable width. After electrophoresis the starch gel was sliced with fine wire and stained in nigrosine[2]. Fig. 1 shows that the agar albumin zones also contained some α-globulins, the thread proteins and a pre-albumin zone.

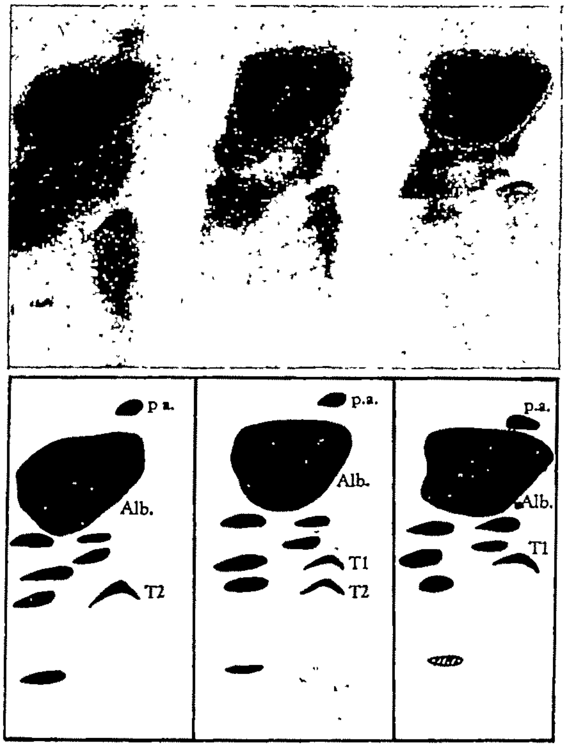

Fig. 1. The three thread-protein phenotypes in pig sera. The illustration shows the agar electrophoresis resolved albumin zones after further resolution in starch gel. The thread-protein phenotypes of the three serum samples are, from left to right, $T2$, $T1/T2$ and $T1$. In order to emphasize the thread proteins the starch gel was somewhat overloaded, resulting in poor resolution of the α-globulin zones. *p.a.*, Pre-albumin; *Alb.*, albumin; $T1$ and $T2$, thread proteins. Remaining zones are α-globulins. The β- and γ-globulins were not presented to the starch gel

The nature of the thread proteins is not clear. In all animals in which they have been found they occupy the same relative position after two-dimensional electrophoresis, that is, at the leading edge of the albumin zone in agar electrophoresis, and well separated from the α-globulins in the second starch-gel electrophoresis. In two-dimensional electrophoresis the thread protein zones usually appear crescent-shaped, a phenomenon not shown by the remaining zones.

Preliminary mating data suggest that the three pig thread-protein phenotypes comprise the two homozygotes and heterozygote of a two-allele system. By analogy with the thread-protein system in cattle it is suggested that the two alleles be named pig T^A and T^B, so that the faster migrating zone $T1$ is seen in the presence of T^A and the slower zone $T2$ is seen in the presence of T^B. The three genotypes T^A/T^A, T^A/T^B and T^B/T^B would then be represented by phenotypes $T1$, $T1/T2$ and $T2$ respectively.

In common with all other mammals so far examined pigs also exhibit β-globulin polymorphism. Three β-globulin phenotypes have been seen in the samples examined, comprising the two homozygotes and heterozygote of a pair of β-globulin alleles, pig β^A and β^B. Each allele gives rise to three zones in starch gel in phosphate buffer, a rather faintly staining zone followed by a moderately staining zone and then by a more intensely staining zone. This is very similar to the situation found in sheep[3], goats[4] and mice (Ashton and Braden, unpublished work). In view of the increasing numbers of β-globulin alleles being found in other mammals, to date five in humans[5], ten in sheep (Ashton and Ferguson, unpublished work) and five in cattle[6], it is very likely that further examples will be found in pigs.

I wish to acknowledge the assistance of Dr. K. C. Sellars in procuring samples of pig sera.

MICROBIOLOGY

L Forms of Bacteria as Contaminants in Tissue Culture

The occurrence of pleuropneumonia-like organism as contaminants in tissue culture is a common experience in many laboratories[1-5]. Such infections may be inapparent or may cause progressive degeneration of the cells. The origin of this type of contamination has never been satisfactorily explained, and although the serum used in tissue culture media is often suspected we have never succeeded in isolating pleuropneumonia-like organisms from many samples of fresh human, bovine, horse and rabbit sera. Our results suggest that at least some of the pleuropneumonia-like organisms found in tissue culture are *L* forms of contaminating bacteria. This belief is based on the following observations.

Twenty cell lines carried in our laboratory yielded minute colonies when the medium in which they had grown was plated on soft meat digest agar containing 20 per cent heated horse serum. A complete minute colony derived from a HeLa culture was inoculated into 5 ml. of meat digest broth containing 20 per cent horse serum, 10 per cent yeast extract, and 100 units of penicillin per ml. This was sub-cultured and when slightly turbid a loopful was stroked out on the solid medium used for the initial isolations. Tiny colonies appeared following incubation for 2 days at 37° C. On the third day most of the small translucent colonies had produced further dense opaque outgrowths. These were found to be composed of a penicillin-sensitive *Corynebacterium*. It was clear that these *Corynebacteria* were derived from the small colonies. Pure cultures of the *Corynebacterium* and its *L* form were maintained in 20 per cent horse serum broth. Penicillin was always added to the *L* form cultures to prevent reversion to the bacterial form.

In order to test the hypothesis that the *Corynebacterium* gave rise to its *L* form in tissue culture, HeLa cultures were cured of *L* form infection by growing them for several sub-cultures in medium containing 200 units of neomycin ('Mycifradin sulphate', Upjohn Co.) per ml. Preliminary experiments had shown that the *L* forms from several cell lines were very sensitive to the tetracycline group of antibiotics and neomycin.

Terramycin, chloramphenicol and aureomycin were found to be toxic for the cells at effective concentrations. However, Hearn *et al.*[4] have used aureomycin at toxic levels to free tissue cultures from pleuropneumonia-like organism contaminants. This hazardous procedure was avoidable since neomycin was effective and had no observable toxic effect on HeLa cells at a concentration of 200 units/ml. At each sub-culture during neomycin treatment some cultures were grown without antibiotics for several sub-cultures with frequent changes of medium. When repeated tests for *L* forms in the medium were negative, the cells were deemed to have been cured. Up to 14 days treatment was necessary in some cases. It is of interest that the cells had to be maintained in medium containing 200 units of neomycin per ml. for several sub-cultures before *L* forms became undetectable, even although the organisms were susceptible to <10 units per ml. of the antibiotic in agar medium. The necessity for this high concentration in tissue culture may be due to poor penetration of the antibiotic into the cell or to some other factor related to the intracellular situation of the *L* form.

Cultures freed from *L* forms were then returned to the original medium with 100 units of penicillin and streptomycin per ml. Some cultures were infected with *Corynebacteria* and others with its *L* form. Although the cells infected with the *L* forms did not appear to be different from the uninfected controls when viewed by low-power microscopy, they had apparently become chronically infected and *L* forms could be isolated regularly from them. In the cultures infected with the *Corynebacterium*, this agent was undetectable in the medium of the infected cultures within 2 days, but persisted intracellularly for 9 days. *L* forms were first detected in these cultures at 6 days and regularly thereafter.

These experiments indicate that contamination of tissue cultures containing penicillin with penicillin-susceptible bacteria may cause an inapparent intracellular infection with the *L* form of the bacterium. This could lead to confusion in antigenic analysis of cells, and in metabolic studies the contribution of the commensal *L* form to the host cells' biochemical activity may be significant and should be excluded.

VIROLOGY

Reactivation of Poxviruses by a Non-Genetic Mechanism

It has recently been shown that poxviruses inactivated by heat are reactivated in cells in which another poxvirus multiplies[1]. The virus yield from cells infected with inactivated virus of one strain and active virus of another strain contains infectious particles of both strains, and also, if the viruses are sufficiently closely related, recombinants[2]. Inactivation by heat, therefore, does not inactivate the deoxyribonucleic acid of the virus particles, since all the known genetic markers are preserved. Since proteins are in general less stable to heat than deoxyribonucleic acid, the role of the reactivating virus may be to provide some essential native protein which has been destroyed by heating. On this hypothesis, it should be possible to use, as the reactivating agent, virus of which the deoxyribonucleic acid has been specifically inactivated. In this case the genotype of the heat-inactivated virus only should survive.

Such inactivation might be achieved by treatment with the nitrogen mustard, di(2-chloroethyl)methylamine, which, although capable of combining with protein, reacts preferentially with nucleic acid. Loveless and Stock[3] have shown that nitrogen mustard inactivates phage probably by combination with its deoxyribonucleic acid without affecting the protein structures responsible for adsorption to host cells and combination with specific antibody, and they particularly comment on the low efficiency of multiplicity and cross-reactivation shown by phage treated with mustard.

Preliminary experiments showed that rabbitpox virus (RPu^+), treated with nitrogen mustard, would reactivate heated RPu^+, and also heated vaccinia *7N*, and that the product had the pock character of the heated parent. In order to provide a sensitive test for partial survival of the genome of the mustard-treated parent, the mutants RP*u*1 and RP*u*8 were chosen as the heated parent. The *u* mutants of rabbitpox virus, which produce white non-ulcerated pocks on the chorioallantoic membrane, differ from the wild type (RPu^+), which produces hæmorrhagic ulcerated pocks, at single genetic sites[4,5]. In mixed infections of the chorioallantoic membrane with RP*u*1 or RP*u*8 and RPu^+, the wild type outgrows both mutants[5], so that if there is survival of that part of the genome which carries the wild locus it should be readily detected.

RPu^+ was inactivated by exposure to various concentrations of nitrogen mustard in 0·005 *M* phosphate buffer, *p*H 7·2, for 20 min. at 37°. The excess mustard was then destroyed by a tenfold dilution of the suspension into 5 per cent sodium thiosulphate and further incubation for 2 hr. Assay of particles capable of reactivating heated virus was carried out by inoculating suitable dilutions of the material on the chorioallantoic membrane of 11-day old chick embryos together with 5×10^8 particles of *RPu*1 or *RPu*8 heated at 60° for 12 min.: the heated virus was completely non-infectious[1]. Residual active particles of RPu^+ were also titrated in the absence of heated virus.

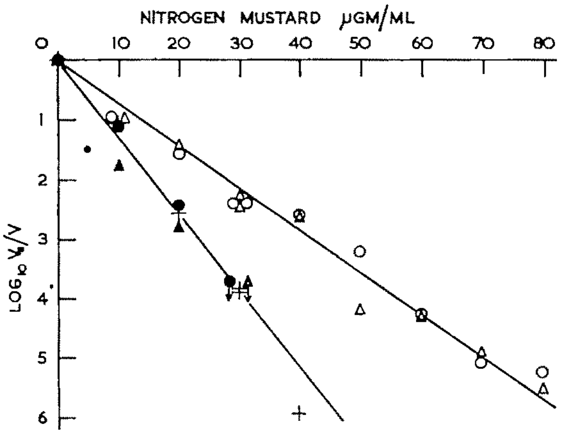

Fig. 1. Inactivation of RPu^+ by nitrogen mustard.
Assayed in the absence of heated virus: +, titre of U$^+$ pocks.
Assayed in the presence of heated RP*u*1: ●, titre of U$^+$ pocks; ○, titre of U pocks.
Assayed in the presence of heated RP*u*8: ▲, titre of U$^+$ pocks; △, titre of U pocks

The results are shown in Fig. 1. The infectivity of RPu^+ is seen to be destroyed by nitrogen mustard by a one-hit process, and the surviving particles can be assayed with equal efficiency in the presence or absence of heated virus. The ability of RPu^+ to reactivate heated RP*u*1 or RP*u*8 is destroyed less readily, though again this appears to be a one-hit process.

It seems, therefore, that in rabbitpox virus all the lethal damages caused by nitrogen mustard prevent expression of the genotype (as judged by one marker), but only about half of them fall in that part of the virus which is necessary for reactivation of heated virus. Thus the evidence is compatible with our hypothesis, namely, that reactivating virus provides some essential non-genetic material which is lacking in heated virus.

We are indebted to Prof. Frank Fenner for the *u* mutants.

Potato Virus *M* and Paracrinkle

Salaman and Le Pelley[1] found that scions of apparently healthy plants of the potato variety King Edward VII grafted on to supposedly virus-free Arran Victory resulted in the latter variety reacting with paracrinkle symptoms, that is, a pronounced deformity and rugosity of the leaves. Although both Kassanis[2] and Macarthur[3] suggest that King Edward contains only a single virus, Bagnall, Larson and Walker[4] found that a stock of King Edward, which they obtained from Canada and which had been supplied originally by Salaman, contained two viruses. One was a strain of virus *S* and the other resembled virus *M* which they had found in Irish Cobbler and several other American varieties. All normal stocks of Arran Victory were found by Macarthur[3] to contain virus *S*. Therefore, even if there are stocks of King Edward with only a single virus, the paracrinkle symptoms observed in Arran Victory after grafting with King Edward may be due either to the King Edward virus (presumably virus *M*) alone or to the combined action of viruses *S* and *M*, as is suggested by Bagnall, Wetter and Larson[5].

We have also found that King Edward apparently contains two viruses. Thus, for example, sap from King Edward inoculated into fathen (*Chenopodium album*) gave symptoms similar to those from virus *S*-infected Arran Victory, and inoculated on to *Datura metel* gave a systemic yellow spotting followed by an acropetal leaf-drop which resulted in the death of the plants. No such symptoms were shown by *Datura metel* inoculated with sap from virus *S*-infected Arran Victory.

By grafting King Edward on to the American variety Saco, which is immune to virus *S*, it was possible to obtain plants, the sap of which gave no symptoms when inoculated on to fathen but still produced virus *M* symptoms in *Datura metel*. Scions from these Saco plants produced paracrinkle symptoms in both virus *S*-infected Arran Victory and in plants of a virus *S*-free stock of Arran Victory produced by Kassanis[6] at Rothamsted by the apical meristem culture method. It would appear, therefore, that paracrinkle symptoms in Arran Victory are produced by the virus *M* component alone of the virus complex found in King Edward.

We are indebted to Mr. E. L. Calvert of The Queen's University, Belfast, for the supply of virus *S*-free tubers of Arran Victory.

AGRICULTURE

Determination of Dieldrin Deposits on Sprayed Mud Surfaces

CHEMICAL investigations into the behaviour of insecticides sprayed on to mud walls require a sampling technique which will remove the insecticide actually present on the surface, and available to the insects, but not that which is sorbed into the bulk of the mud. For laboratory work, Barlow[1] has used 'Sellotape' for this purpose, while Alessandrini[2] has used parchment paper coated with a film of silicone grease. Both these techniques suffer from the disadvantage that the sticky material which is used to pick up the insecticide particles is mounted on a comparatively rigid backing, which prevents its penetrating into the small depressions and irregularities which generally occur on mud surfaces, and which are accessible to insects. Unrealistically low figures are therefore obtained. It was thought that this difficulty might be overcome by the formation of an adhesive film *in situ* on the mud surface, and it has been found that in the laboratory satisfactory films for this purpose can be obtained using solutions containing 1–2·5 per cent w/v of high-viscosity grade (1,500–2,000 cp. for a 1 per cent solution at 25° C.) sodium carboxy-methyl cellulose. The addition of glycerol to the sodium carboxy-methyl cellulose solution is usually necessary; in most cases up to 5 per cent v/v suffices to give a pliable film, but on certain muds up to 25 per cent v/v of this has been necessary to prevent the formation of a hard, brittle film which removes an excessive amount of mud.

The sodium carboxy-methyl cellulose solution is applied to the mud surface mounted on a piece of cotton gauze and should be removed as soon as possible after drying is complete. The film is separated from the gauze by soaking in cold water, and, to ensure complete extraction of the insecticide, the resulting solution is treated with sodium hydroxide and potassium permanganate, and allowed to stand for 30 min. Excess permanganate is removed by careful acidification and treatment with sodium bisulphite. The insecticide is then extracted from the mixture with a suitable solvent, and determined by any convenient method. In the experiments described below, *n*-hexane was used as solvent, and a total chlorine determination using sodium diphenyl reagent was employed. Subsidiary experiments showed no significant loss of dieldrin occurred during the extraction and subsequent treatment.

A series of glass plates and blocks of Uganda mud were sprayed with an aqueous suspension of a dieldrin 50 per cent wettable powder; weighing of the plates before and after spraying showed an average deposit of 114 mgm. dieldrin/sq. ft. Using the above technique, recoveries of 86, 84, 92 and 82 mgm./sq. ft. were obtained from the surfaces of the mud blocks. A similar series of experiments using blocks of Babati (Tanganyika) mud gave recoveries of 74, 83 and 76 mgm. dieldrin/sq. ft., compared with an average deposit of 100 mgm./sq. ft. indicated by weighing of the glass plates. These figures indicate a recovery of between 70 and 80 per cent from both types of mud, and this is adequate to enable sorption to be demonstrated, as shown by the results in Table 1, which were obtained by spraying three series of mud blocks with a dieldrin 50 per cent wettable powder at 65 mgm./sq. ft. and determining the surface deposit at various times after spraying.

Table 1

Days after spraying	Dieldrin recovered (mgm./sq. ft.)		
	Babati	Uganda	Mexico, D.F.
0	54	49	50
1	—	7·0	39
2	—	5·5	—
7	9·7	3·7	24
14	4·0	2·5	15

Results are given for three muds, two of which (Uganda and Babati) have been shown from biological data to be highly active in sorbing dieldrin, and the third (Mexico D.F.) to be less active.

This technique has been tested satisfactorily in the laboratory on a number of different types of mud, although the concentrations of sodium carboxymethyl cellulose and glycerol required to give the most satisfactory film vary from one to another. Provided that care is taken in removing the film, the amount of mud removed is very small; it has been observed, however, that this is apt to vary with the type of mud used, and this factor should therefore be borne in mind when comparing results of experiments carried out on different muds. The applicability of this technique to muds which give a very loose and friable surface has not been examined.

Thanks are due to "Shell" Research Ltd. for permission to publish this work, and to various colleagues in this laboratory for helpful discussion and assistance with the analytical determinations.

FORTHCOMING EVENTS

Monday, June 20—Thursday, June 23

Laboratory Apparatus and Materials Exhibition (at the Royal Horticultural Society's New Hall, Westminster, London, S.W.1).

Wednesday, June 22

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. R. W. Fairbridge and Dr. Heli Badoux "Slump Blocks in the Cretaceous of Northern Syria"; Dr. L. J. G. Schermerhorn and Dr. W. I. Stanton. "'Tilloids' in the West Congo Geosyncline".

Challenger Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 5.45 p.m.—Miss Alison Kay: "The Ecology of the Hawaiian Species of *Cypraea*".

Friday, June 24

Victor Horsley Memorial Fund (in the Great Hall, British Medical Association House, Tavistock Square, London, W.C.1), at 11 a.m.—Prof. Norman M. Dott: "Brain, Movement and Time" (Eleventh Victor Horsley Memorial Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Senior Lecturer (with a good honours degree and teaching or other suitable experience) to teach Electronics and Mathematics to equivalent degree level for sandwich diploma courses—The Principal, Royal Radar Establishment, College of Electronics, Malvern, Worcs (June 22).

Assistant, Grade B, in Mathematics; and a Lecturer (able to teach to special (honours) degree standard) in Inorganic Chemistry—Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (June 24).

Senior Lecturer (with high qualifications and wide experience) in Physics, to teach to honours degree level—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (June 24).

Assistant Lecturer in Numerical Analysis—The Registrar, The University, Manchester 13 (June 25).

Lecturer (with medical qualifications registrable in this country) in Anatomy—The Registrar, The University, Manchester 13 (June 25).

Scientific Officer (male, with a good honours degree) for genetical, physiological and breeding research in barley—The Secretary, Plant Breeding Institute, Trumpington, Cambridge (June 25).

Assistants (2) in Zoology, one in the field of vertebrate zoology, and the other in comparative physiology—The Secretary of University Court, The University, Glasgow (June 27).

Research Assistant (with a good degree and preferably a higher degree, in physics, chemistry, engineering or ceramics) at the Houldsworth School of Applied Science, to work on the high-temperature properties of certain ceramics of potential interest as engineering materials—The Registrar, The University, Leeds 2 (June 27).

Lecturer in Psychology or a Temporary Lecturer in Psychology—The Secretary, The Queen's University, Belfast (June 29).

Lecturer or Assistant Lecturer in Applied Mathematics—The Secretary, The University, Exeter (June 30).

Research Assistant (with a biological first degree and research experience) in Tissue Culture, to take part in a programme of research in the behaviour of normal and malignant cells—The Secretary, University College, Gower Street, London, W.C.1 (June 30).

Assistant Experimental Officers, Chemists (with G.C.E. "A" level in chemistry or physics and another science subject or equivalent, if over 22 a pass degree in chemistry or microbiology or H.N.C. chemistry generally expected), at the Water Pollution Research Laboratory, D.S.I.R., Stevenage, Herts, for research on physico-chemical and biological problems in the study and prevention of the pollution of rivers—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.384/0A (July 1).

Research Student (with the degree of Bachelor or Master of a British university other than Manchester) in Science—The Registrar, The University, Manchester 13 (July 1).

Lecturer, and a Demonstrator (honours graduates in geography) in Geography, at the University of New England, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 2).

Research Assistant in the Department of Botany, to work for one year on the acetate metabolism of the alga *Chlorella*—The Secretary, University College, Gower Street, London, W.C.1 (July 4).

Lecturer or Assistant Lecturer in Inorganic Chemistry in the Faculty of Science—The Registrar, The University, Manchester 13 (July 8).

Bacteriologist (honours graduate, majoring in bacteriology or biochemistry, with some years research experience in bacteriology) at the Meat Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Brisbane, Queensland, Australia, to supervise the work of a small group investigating the metabolism of psychrophilic micro-organisms and the application of the results to the microbiology of chilled and frozen meat—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 305/61 (July 9).

Biochemist, basic grade (with a first- or second-class degree in biochemistry, chemistry or physiology, or equivalent) in the Department of Chemical Pathology, to carry out research on lipid metabolism in disease—The Secretary, The United Liverpool Hospitals, 80 Rodney Street, Liverpool 1 (July 9).

Lecturer in Zoology in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (July 9).

Lecturer (with a good honours degree and preferably experience in the general field of applied mechanics) in the Department of Mechanical Engineering—The Registrar, The University, Liverpool, quoting Ref. CV/T (July 9).

Lecturer in the Computer Unit—The Director, University of London Computer Unit, 44 Gordon Square, London, W.C.1 (July 10).

Scientific Officer, Grade I (with an honours degree in mathematics or physics, and preferably relevant experience), at the Weapons Research Establishment, Salisbury, near Adelaide, South Australia, for research and development on frequency response techniques in optics—The Senior Representative (AV.63/1), Department of Supply, Australia House, Strand, London, W.C.2 (July 11).

Senior Lecturers/Lecturers (with an honours degree or equivalent, and in the case of Senior Lecturers a higher degree) in Applied Mathematics at the University of New South Wales, Australia—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2 (London and Australia, July 15).

Lecturer or Assistant Lecturer in the Department of Botany—The Registrar, The University, Edgbaston, Birmingham 15 (July 16).

Senior Lecturer in Physiology; and a Lecturer (Grade I) in Biochemistry in the Department of Physiology, University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (July 18).

Chairs of Botany, Chemistry, Mathematics, Physics and Zoology in the Royal Technical College of East Africa and proposed University College in Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 25).

Lecturer in General Psychology—The Secretary of Faculties, University Registry, Oxford (July 25).

Associate Professor (with a higher degree in pharmaceutics and wide teaching and research experience in physico-chemical or microbiological applications to pharmaceutics) of Pharmaceutics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 29).

Assistant Lecturer (preferably candidate hoping to undertake research in the general field of genetics) in the Department of Zoology—The Secretary, University College, Gower Street, London, W.C.1 (July 31).

Laboratory Superintendent in the Department of Physics, Fourah Bay College (University of Durham), Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 31).

Lecturer (with at least a good honours degree in geography and preferably experience of teaching geography in a university department) in Geography at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, July 31).

Senior Lecturer (with a Doctorate of Philosophy of Science conferred for research in some branch of physics) in Physics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, August 15).

Lecturer in Microbiology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, August 31).

Reader in Mathematical Statistics at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, August 31).

Assistant Professors (2) (with experience in the teaching of gross anatomy, and preferably willing to undertake some teaching in neuroanatomy, histology, or embryology) in the Department of Anatomy—Prof. R. L. de C. H. Saunders, Anatomy Department, Dalhousie University, Halifax, Nova Scotia, Canada.

Biochemist, basic grade—Dr. Walker, Biochemistry Department, Royal National Orthopædic Hospital, Stanmore, Middlesex.

Biochemist (with biological interests), to assist in research on the plasmin–anti-plasmin system—The Pathologist, Institute of Orthopædics, Royal National Orthopædic Hospital, Brockley Hill, Stanmore, Middlesex.

Biologist (with biochemical training), to assist in research on the plasmin–anti-plasmin system—The Pathologist, Institute of Orthopædics, Royal National Orthopædic Hospital, Brockley Hill, Stanmore Middlesex.

Chemist (with a good honours degree in chemistry or equivalent professional qualification and specialization or interest in inorganic analysis) in the Geological Survey Department, Tanganyika, for the analysis of rocks, minerals and ores, and the supervision of junior staff in routine analytical work—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/8/09/T.

Editorial Assistant (graded Assistant Experimental or Experimental Officer) (with G.C.E. "A" level in two science or a science and mathematics subject, or equivalent, if over 22 a pass degree, H.N.C., or equivalent, generally expected) in the Publications Section, Road Research Laboratory, D.S.I.R., Harmondsworth, Middlesex, for work involving editing and preparing for publication articles to technical journals, official booklets issued by the Laboratory, etc.—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.21/0A.

Graduate Demonstrators (male, with a first- or second-class honours degree or equivalent) in Civil, Mechanical and Electrical Engineering, Physics, Metallurgy and Ballistics, at the Royal Military College of Science, Shrivenham, Berks—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. A.266/0A.

Junior Research Fellow in Physics—The Registrar, The University, Sheffield.

Lecturer in Physics, to teach Ordinary National Certificate and B.Sc. general degree students—The Principal, Peterborough Technical College, Eastfield Road, Peterborough.

Lecturer or Assistant Lecturer, Grade B, in Mechanical Engineering—The Principal, Kingston Technical College, Fassett Road, Kingston-on-Thames.

Research Assistant (preferably with experience in cytology), to take part in a programme designed to study human chromosome abnormalities and associated disorders—The Secretary, Genetics Department, The University, Sheffield 10.

Research Biochemist to work in the Department of Hæmatology on fractionation of blood components—The Secretary (R), The Hospital for Sick Children, Great Ormond Street, London, W.C.1.

Research Fellow (preferably with an interest in solid state physics or nuclear physics) in Theoretical Physics—Prof. M. A. Preston, Department of Physics, McMaster University, Hamilton, Ontario, Canada

Research Student (physicist, electrical engineer, or physical chemist, with a first degree from the University of London) in the Department of Electrical Engineering, for work in the field of ultrasonics—The Registrar, Royal Technical College, Salford 5, Lancs.

Senior Bacteriologist (Principal Scientific Officer), and a Bacteriologist (Scientific or Senior Scientific Officer) with the East Africa Veterinary Research Organization, Kenya, for research into bacteriological and immunological problems relating to animal disease but primarily for basic studies on immunology with a view to developing a satisfactory vaccine for use in African conditions against bovine pleuro-pneumonia—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/214/02.

Senior Lecturer (with a first- or second-class honours degree or equivalent in physics, preferably with teaching and/or research experience) in Physics at the Royal Military College of Science, Shrivenham, Berks, to lecture to degree courses (and possibly specialized courses), and assist with laboratory classes—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.265/0A.

Senior Lecturers, Lecturers, or Assistants, Grade B (preferably with special interests in applied analysis, mathematical statistics, or other branches of applied mathematics) in the Department of Mathematics—The Academic Registrar, Hatfield Technical College, Hatfield, Herts.

Senior Technician or Technician for duty in the Clinical Isotope Laboratory—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Temporary Demonstrators (with a good honours degree or equivalent qualification) in Physical and in Inorganic Chemistry—The Registrar, The Manchester College of Science and Technology, Manchester 1.

THE BALANCE OF SCIENTIFIC AND INDUSTRIAL RESEARCH

THE White Paper, "Industrial Research and Development Expenditure, 1958" *, issued by the Department of Scientific and Industrial Research, is somewhat slighter than that issued in 1958 under the title "Estimates of Resources devoted to Scientific and Engineering Research and Development in British Manufacturing Industry, 1955"; but it is claimed to be somewhat more accurate as a result of improvements in the method of compilation. Moreover, it is of particular interest at the present moment when the abandonment of the *Blue Streak* missile project has raised major issues in defence research policy and in our effort in space research, for the report brings out some remarkable changes in British industrial research and development during the period of three years. The trends revealed bear closely both on the relation of defence research to the civil economy and on the effort which Britain can afford to devote to space research.

Taking first the broad picture, the report estimates that in 1958 British manufacturing industry spent about £380 million on research and development (compared with an estimate of £190 million in 1955) or 4·2 per cent of manufacturing industry's contribution to national production (compared with 3·1 per cent in 1955). Of the total, 95 per cent was spent in industrial establishments, and about 5 per cent (£13·7 million) on payments to outside bodies, among which co-operative research associations took some 29 per cent, the universities about 4 per cent, and other research institutions 65 per cent. These included independent research institutions and industrial consultants, but, particularly in the newer electrical and motor vehicle industries, payments were largely for technical information from other companies, often parent or associated companies overseas. Such expenditure to outside bodies was highest in industries comprising a large number of small manufacturers, which tended to concentrate their effort in the co-operative research associations.

These figures suggest that research and development have more than kept pace with the change in the value of production. The volume of production during the period changed only very slightly, and the Economics Committee, over which Prof. C. F. Carter presided, responsible for the report, is confident that this conclusion cannot be invalidated by any imperfections in the statistics. The second broad conclusion that is particularly pertinent just now is that the proportion of expenditure on research and development in establishments maintained by manufacturing industry provided out of defence contracts has fallen from nearly two-thirds to less than half, so that in the period the expenditure on 'civil' research and development has approximately doubled.

The basic method used in this inquiry was to apply to the estimates of fully qualified man-power engaged in research and development obtained by the Ministry of Labour from all manufacturing establishments employing 500 persons or more, and to a sample of those employing between 11 and 499 persons, estimates of cost per fully qualified person obtained, industry by industry, from a sample questionnaire addressed by the Department of Scientific and Industrial Research to 502 companies. There was an 80 per cent response to the Ministry of Labour inquiry, and the replies from 292 companies to that of the Department of Scientific and Industrial Research covered 1,044 establishments, including nine central research establishments serving an unspecified number of factories. Together with data from an inquiry made by the British Iron and Steel Federation, the latter return accounted for more than half the fully qualified scientists and engineers estimated to be employed on research and development in all manufacturing industry in Britain other than the aircraft industry, and the estimates are regarded as more reliable than those for 1955.

The estimates of cost per qualified worker vary greatly from one industry to another, being related to the weight of development expenditure and to the amount of use made of supporting staff. In its own establishments, all manufacturing industry employed on research and development 113,508 workers, of whom 26,225 or 23 per cent were qualified scientists and engineers. The average cost per qualified worker is thus £10,791; but if the aircraft industry is excluded (for which the figure was nearly £31,000) the average falls to £7,968, which compares with an estimate of £5,600 in 1955. An increase of 14–15 per cent can be attributed to rising prices and incomes, but, even at constant prices, there appears to have been an increase in expenditure per qualified worker of about 27 per cent, attributed partly to an increase in the number of supporting staff, from about two in 1955 to three per qualified worker in 1958. The chemical and allied trades (6,368 out of 20,476) and electrical engineering and electrical goods (7,677 out of 31,848) employed the largest number of qualified workers in research and development and the cost per qualified worker was £6,655 and £7,472, respectively. These two industries accounted for £43 million and £64·5 million, respectively, of the expenditure on research and development, and the aircraft industry for £100 million; but it must be remembered that about 80 per cent of the defence contracts for research and development were let to the electrical engineering and the aircraft industries.

---

* Department of Scientific and Industrial Research. Industrial Research and Development Expenditure, 1958. Pp. iv+13. (London: H.M. Stationery Office, 1960.) 1*s*. 3*d*. net.

These estimates of expenditure on research and development, when compared with estimates of net output, again show remarkable variations between industries. Covering all industries, research and development expenditure averaged 3·8 per cent of net output; but if the aircraft industry, for which the figure was 35·7 per cent, is left out, the average is 2·6 per cent. For the industries based on science, such as electrical engineering (11·9), precision instruments (10·7) and the chemical industries (5·9), the figure was appreciably higher; whereas in the traditional industries such as food, drink and tobacco or manufactures of wood and paper and printing, it was as low as 0·6 per cent and 0·25 per cent, respectively. Capital expenditure accounted for just over 10 per cent (£29 million) of the total expenditure of manufacturing industry on research and development in its own establishments, and of this sum more than half was incurred by the chemical and engineering industries.

Looking at the total of £13,664,000, estimated as paid by manufacturing industry in Britain to outside bodies in 1958, it should be noted that the £546,560 going to the universities should be put alongside £2,286,212 provided from Government departments to the universities in 1959–60 and £2,797,060 provided in the 1960–61 estimates for specialized researches. This is included in the vote of £65,670,790 for the universities through the University Grants Committee, of which £42 million is by way of recurrent grants. But there appear to be no published figures for the expenditure on research and development by the Atomic Energy Authority, the vote for which in the 1960–61 estimates amounts to £92 million, apart from £5,430,000 on research and development contracts with industry, the universities, etc. It should be recalled that such expenditure by the Industrial Group alone increased by 280 per cent between 1956–57 and 1959–60, and the volume of such work placed with industry is to be trebled in the next few years.

The present review of research and development expenditure in industry loses something of its value for assessing the balance of the research effort in Britain through the absence of accurate figures for the corresponding Government expenditure against which to compare it. In opening a debate on capital investment in industry in the House of Commons on April 26, Mr. J. H. Osborn, who referred to the White Paper, put Government expenditure on civil research at about £38 million, with a further £204 million on defence research and £5·3 million by the nationalized industries. He did not indicate the source of his figures, and his total of £242 million compares with an estimate of £277 million given by the Financial Secretary to the Treasury in a memorandum on the Civil Estimates.

Even this total of £277,748,774, however, is incomplete. It includes £202,150,000 on research and development by the Ministry of Aviation, of which £162,920,000 is for research and development work by industry, £18·5 million on scientific services by the Admiralty, with another £12·29 million on shipbuilding, repairs, maintenance, etc., £544,000 on medical research by the Air Ministry, £650,000 on meteorological research and £137,000 on operational research. Then there is £459,350 on the Chief Scientist's Department of the Ministry of Power, £287,424 on the Science Museum, £793,200 on the Directorate of Overseas Surveys and £200,000 on Overseas Geological Surveys. On the other hand, some at least of the expenditure included, that on research under the Home Office, for example, is scarcely of scientific significance, though some of the £15,754,514 for educational services and research, not included by the Financial Secretary, could be.

Most of these items, however, are comparatively minor, though the absence of any figures for the Atomic Energy Authority and the nationalized industries is a major matter, even if only the first falls properly within the Civil Estimates. More significant, however, is the omission of the contributions made to research through international bodies; for example, £1,330,000 through the Department of Scientific and Industrial Research to the European Organization for Nuclear Research, £204,000 to the International Atomic Energy Agency, £300,000 to the European Nuclear Energy Agency, £1,242,000 to International Atomic Energy projects, and £6,250,000 in grants to the Nuclear Research Institute (all these through the Atomic Energy Authority), or the £125,925 to the scientific schemes of the North Atlantic Treaty Organization. Such contributions might become more important if the trend away from defence research revealed by the inquiry continues, and if the trend to co-operative research with other members of the North Atlantic Treaty Organization develops.

Such a trend is suggested both by the discussions arising out of the Government decision to abandon the development of *Blue Streak* as a missile and by the conclusions of Mr. D. Wilgress in his report to the Organization of European Economic Co-operation on "Co-operation in the Field of Scientific and Technical Research"*. Little was, in fact, said about this aspect in the House of Commons debate, although some increase in our investment in research and development was urged, and there was little support for a view expressed by Lord Grantchester in the House of Lords that it is possible to spend too much money on research; nevertheless, Mr. H. Rhodes suggested that in some industries scientific research is badly applied. The question of balance between fundamental and applied research or between the research effort conducted by industry itself, by Government departments and institutions, and by the universities and research institutes was not mentioned, and yet this balance may be all-important in considering whether or not Britain should extend its effort in certain of the more costly and spectacular fields at the expense of other fields requiring attention.

This question of balance is strongly emphasized by Mr. Wilgress in his report, which in fact includes several tributes to the British effort and its organization; for example, the development of the research association system and the device of the National Research Development Corporation. Mr. Wilgress was asked to discuss with government authorities as well as with senior representatives of national administrations, science and industry, the measures already taken or planned to intensify the scientific and technical resources of each member country of the Organization, to make those in high authority aware of the importance which scientific research and technological development are likely to have on the future economy, and to propose measures to increase technological resources and to favour the establishment of common action for their more rational use.

---

* Organization for European Economic Co-operation. Co-operation in the Field of Scientific and Technical Research. Report by Mr. D. Wilgress. Pp 27. (Paris. Organization for European Economic Co-operation, 1960.)

While he found an encouraging and increasing awareness in the past three years of the need for greater scientific and technological activity, Mr. Wilgress regards Europe as falling far behind the United States in utilizing the results of applied science. He makes some comments on the educational system, including the place of fundamental research in the universities and the need to ease some of the existing rigidities in the educational systems of Europe. He points out that the solution of really difficult problems in fundamental research is best left to the initiative and imagination of eminent scientists, although when more than one branch of science is involved, the team concept becomes useful. He recognizes the difficulty which sponsored research presents to the universities, but suggests that use of this method deserves some attention from the Organization for European Economic Co-operation, and an analysis of sponsored research in Europe made by Dr. F. N. Woodward (see *Chem. and Indust.*, 33; 1960) certainly suggests that there is plenty of scope for development.

On the whole, Mr. Wilgress considers that more intensive scientific research is a matter for national rather than international effort. His recommendations for reorganizing the scientific activities of the Organization are, in fact, strictly limited. He suggests that its Committee of Applied Research should in future report direct to the Council, and that it should be known as "The Committee for Scientific Research", so that it would cover the broad field of scientific research while concentrating on those aspects with important economic implications. Eventually he visualizes the Governing Committee for Scientific and Technical Personnel as merging with this Committee, and in the meantime he suggests the establishment of a scientific advisory committee of seven or nine persons, each serving in a personal capacity, to advise the Council on the general scientific policy of the Organization.

Mr. Wilgress concludes that the Organization for European Economic Organization is the only international organization in a position to develop co-operation in scientific and technical research between the countries of Europe. Such co-operation for economic ends will be increasingly important, and Mr. Wilgress fully recognizes the need to develop co-operative efforts in fundamental research, particularly the replacement of weak institutes by one strong one, though he also appreciates the value in fundamental research of work proceeding in several places. His stress is on the importance of wise and inspiring leadership, and he insists throughout that while the Organization offers the best scope for increasing European co-operation in science, such co-operation should have an economic basis or implications, and the Organization's real function is to assist in fact-finding and the dissemination of information and to stimulate the development of the scientific and technical resources of member-countries in the interest of the economic growth of Europe as a whole. He lends no support to the launching of projects involving large sums of money, and his very sensible report emphasizes points that we in Britain need to keep carefully in mind in considering the balance of research and development in Britain, and the effect on that effort of any large new undertaking whether in space research or elsewhere.

QUANTUM THEORY FOR THE SCHOLAR

Mécanique Quantique

Par Prof. Albert Messiah. Tome 1. Pp. xv+430. 3,900 francs. Tome 2. Pp. xvi+544. 4,800 francs. (Paris: Dunod, 1960.)

Principles of Quantum Electrodynamics

By Walter E. Thirring. Translated from the German by J. Bernstein. (Pure and Applied Physics: a Series of Monographs and Textbooks, Vol. 3.) Pp. xv+234. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 8 dollars.

TEXT-BOOKS on quantum theory in general and monographs on special topics in this field are appearing nowadays at an ever-increasing rate. "Mécanique Quantique" by Messiah is the latest addition to the text-book literature. It is of considerably more than average length; other authors usually cover much the same ground in less volume. This does not mean to say, however, that this work is verbose; given the author's intention, he could scarcely have made it shorter.

To-day there are basically two methods of expounding quantum theory—either one presents the theory as a set of rules, the justification of which is that they form a logically consistent scheme capable of describing Nature correctly, or alternatively, one traces the historic development, discusses the inevitability of quantum theory superseding classical theory and leads up, step by step, to the general rules. On a previous occasion I have remarked that perhaps it is time to move away from the idea that the second, historical approach to quantum mechanics is essential to a first introduction to the subject. In any event, quantum theory has many users to-day who are not primarily interested in the foundations of the discipline. The present volumes are not for these, but the student who wishes to go deeply, to understand, not just to use, should welcome the existence of an exposition such as this, which takes him carefully along the traditional road of approach with much attention to detail, but without ever losing a basic unity of outlook that makes the book eminently readable despite its length. Lest English readers may be deterred by the language barrier, let it be said that the characteristics of clarity and simplicity extend to the language side also. The general contents of the volumes are much what one would expect, though it should be noted that the stress throughout is on general questions rather than on applications. Thus, to give but one example, the structure of the Periodic Table is treated with unusual brevity and the structure of molecules is not discussed at all. On the other hand the appendixes include a full summary of mathematical group theory. Like most text-books the reader is taken right up to relativistic theory, with a chapter on the Dirac electron and a sketch of quantum electrodynamics. Such final chapters are of course only useful in providing the 'further outlook' that whets the reader's appetite. To treat them in detail in the author's individual style would surely have required two further volumes.

Thirring's "Principles of Quantum Electrodynamics" deals with precisely the last-mentioned questions. Superficially at least it is diametrically opposed to what one imagines a continuation of Messiah would be. This is a translation of a book that originally appeared in German and was at the time most favourably acclaimed by the experts. Though the English edition is an expanded version of the original, brevity is, even now, an outstanding characteristic of this author's style. Perhaps the most notable single aspect of this work is its combination of fully up-to-date mathematical treatment with a continual stress on the physical meaning of the formalism. However, for entirely different reasons, one can say of this work just as of Messiah's that, while it is probably not the best first introduction to this field, it is eminently recommendable to the reader who seeks to acquire depth of understanding—and not merely dexterity in manipulation—in a difficult subject.

Advances in Agronomy

Vol. 10. Pp. xii+547. 12.50 dollars. Vol. 11. Pp. x+428. 12 dollars. Edited by A. G. Norman. (Prepared under the auspices of the American Society of Agronomy.) (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1958–59.)

WHAT *is* agronomy? Certainly, like 'billion' and 'suspender', it suffers a potentially embarrassing change of meaning in crossing the Atlantic. In England, little would be left for agronomy when the claims of chemistry, entomology, plant pathology and so on had been stated—perhaps the study of green manuring, seed-rates and sowing dates.

In the United States apparently the subject of agronomy comprises pretty well all agricultural science. Subjects covered by the present volumes range from liming to castor-beans and from wheat stem rust to water and its relation to soils and crops.

"Advances in Agronomy" is written mainly by Americans about conditions in the United States; out of 17 articles only 2 come from institutions in other countries. (References to recent British work are very rare.) Many articles (especially those on soil chemistry) deal with fundamental work and make little reference to field experiments or practice. Many are rather turgid summaries of their subjects, devoting only small space to recent advances.

Among articles which appealed to me are those on individual crops (safflower and castor-beans) and on stem rust of wheat; the last is an excellent account of the difficulties of plant breeders competing with an adaptable air-borne pathogen. The article on recent developments in agricultural machinery in the United States is excellent and is one of the few articles of direct interest to British farmers.

Two articles come from outside the United States. One is a full account of the classification of the soils of Australia with their pedological descriptions; the known incidence of mineral deficiencies is concisely set out on maps. The other deals with the soils of Holland, relating their origins to their present appearance and the farming systems which have been established on them.

The articles in these two volumes, with a few exceptions, read like a disjointed collection of condensed text-books, or chapters from text-books. The range of subjects covered is far too wide to justify the implied suggestion that they are all branches of one science. These volumes do not establish 'agronomy' as a science.

G. V. DYKE

FLUID DYNAMICS: A MIXED BAG

Fluid Dynamics

By Dr. D. E. Rutherford. (University Mathematical Texts.) Pp. ix+226. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1959.) 10*s*. 6*d*. net.

Introduction to the Theory of Compressible Flow

By Prof. Shih-I Pai. Pp. xiii+385. (New York: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1959.) 9.75 dollars; 73*s*.

Fluid Mechanics

By L. D. Landau and E. M. Lifshitz. Translated from the Russian by J. B. Sykes and W. H. Reid. (Course of Theoretical Physics, Vol. 6.) Pp. xii+536. (London and New York: Pergamon Press, 1959.) 105*s*. net.

AS an aftermath of the rapid development of fluid dynamics during and since the Second World War, books recording new results or re-interpreting old results are now appearing in large numbers. The variety of books on fluid dynamics is also increasing, and the above three volumes in particular are widely different in purpose, style and content.

Dr. Rutherford's addition to the valuable series of University Mathematical Texts is aimed at undergraduates taking an honours course in mathematics in Britain. This is a sensible aim, for there is a dearth of introductory texts on fluid mechanics that are up to date in spirit as well as in content. Most teachers of the subject are aware that the older books, which concentrated on 'perfect' fluids because greater analytical development was thereby made possible, are not very useful to-day and may even be educationally harmful. It is possible nowadays to teach aspects of theoretical fluid dynamics which are fundamental, which are capable of mathematical expression and elaboration, and which describe accurately what happens in reality; but the books which discriminate properly between what is merely a mathematical exercise without physical significance and what is sound theory are not yet numerous.

In accordance with this need, Dr. Rutherford has devoted nearly a half of his book to non-perfect fluids (first compressible and then viscous), and the book is given a physical flavour by the inclusion of four plates of flow photographs. The jacket claims that "care has been taken to emphasize the distinction between real fluids and the mathematical models in terms of which the applied mathematician makes his calculations". I do not think this claim is justified; and, inasmuch as the author seems to me not to have succeeded in this absolutely vital test, I am doubtful if his book has any advantages over older texts, except the undoubted merit of cheapness. Dr. Rutherford's other contributions to the series of University Mathematical Texts have been on less physical subjects and have been well received. In his new book there is the same clear exposition and appreciation of the needs of students, but there are many places where he reveals his amateur status and his lack of acquaintance with the realities of fluid mechanics. Perhaps the most important fact about a viscous or 'real' fluid is that the flow past a bluff body is in general not approximately the same as for a completely inviscid or 'perfect' fluid, not even when the viscosity is extremely small, and if the inclusion of a discussion of viscous fluids in an introductory text has point at all, it is surely to reveal this limitation on the applicability of inviscid fluid theory; but a statement to this effect is not to be found here, either in a general discussion or *à propos* of particular cases. The author repeats the old fallacy about fluid not being able to go round sharp edges because of "the physical impossibility of having an infinite fluid velocity", and this is made the basis of Joukowski's hypothesis about the circulation. He includes the change in internal energy of a gas in the expression for the "rate at which energy is being dissipated into heat". Such comments (which could be multiplied) would be captious if the more purely mathematical qualities of the book compensated for the lack of physical understanding. These mathematical qualities do exist, but they also exist in many older books. I feel that Dr. Rutherford has added one more to the list of text-books on fluid dynamics about which students have to be warned; although in view of its handy size and appealing price his book may well be the one students choose in spite of the warning.

Prof. Pai's book is quite different in type. He has prepared an account of the flow of compressible fluid, which, so far as level of treatment is concerned, is suitable for postgraduate students and for those taking up research in the subject. The military and technical importance of high-speed flow has led, by the usual unseen but inexorable processes, to this part of fluid dynamics being the favourite of young research workers (or did until recently, when magnetohydrodynamics became the 'chosen'-subject and displaced it), and there is a large and hungry market seemingly able to consume any number of books like this one. Avid readers encourage hasty authors, and the breathless unscholarly style of Prof. Pai's book will deter those who look to a book for enlightenment as well as information. There is insufficient space here for a detailed account of the contents of the book and of its merits; it must be sufficient to say that the scope of the book is very wide and that something is said on almost all aspects of gas dynamics, some of them quite advanced and the subject of current research. The writing is not careful, and the author's explanations of fundamentals do not inspire confidence. He has, perhaps, done research beginners a good turn in gathering so much material together, but they will need guidance in their use of it.

"Fluid Mechanics", by Landau and Lifshitz, is a translation from Russian of one of a set of nine volumes making up the authors' "Course of Theoretical Physics". The authors are already well known by name to Western physicists, but it is a fair guess that they will be much more widely known as a result of the translation of these nine volumes. When I first saw a list of the titles of the nine volumes, I ungenerously inferred that the volumes on theoretical classical physics (like the present one) had probably been written out of determination to be absolutely complete, and that they would be poor relations to the volumes on quantum mechanics, field theory and statistical physics. Reasonable though this inference may have been, at least if the authors had been theoretical physicists from Europe or America, it is in fact quite unjust here. We have been given 536 pages of first-rate writing, with no hint that the authors found the material any less interesting than that in their other volumes. The authors have surveyed the whole field of fluid mechanics, from a fairly advanced point of view, and, although the different branches of the subject are of course not carried to the boundaries of current research, the book is extraordinarily interesting to both teacher and specialist. Analytical lucidity of the kind expected of good theoretical physicists has been combined with remarkable breadth of knowledge of the subject (one's mind boggles at the thought of equal erudition displayed on eight other subjects) to produce a book of unusual quality.

It must be owned that it is not a book for beginners; a good deal of background material is taken for granted, and some of the arguments are rather sophisticated. Nor is it likely to be very useful for routine reference, since the authors' choice of material is sometimes strange and unsystematic and, moreover, they have made little attempt to include experimental data. But for a theorist who is advanced enough to appreciate new views on innumerable results, some standard and some merely 'well known', the book is a gold mine.
G. K. Batchelor

THIRD CANADIAN CANCER CONFERENCE

Canadian Cancer Conference

Vol. 3: Proceedings of the Third Canadian Cancer Research Conference, Honey Harbour, Ontario, June 17–21, 1958. Edited by R. W. Begg. Pp. xiv+461. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.) 12 dollars.

At this conference twenty-eight papers were presented on nucleic acids, genetics, viruses and tumours, and on the biology of cancer. At the two earlier conferences the subjects chosen were:

(1) experimental tumours, tumour–host relations, enzymes, ionizing radiation; (2) the cell, leukæmia and chemotherapy, hormones and cancer, immunity and basic mechanisms. Thus the organizers of the three conferences seem to have avoided any bias towards (*a*) carcinogens and carcinogenesis, and (*b*) environmental factors and the demography of cancer.

The first section of the third conference deals with nucleic acids and consists of nine papers. Their relation to the cancer problem is somewhat indirect and the term 'cancer' is brought in here and there a little surreptitiously; however, the nucleic acids are an important theme at most centres of cancer research at the present time.

The second section, on genetics, consists of seven papers, a few of which have a more direct bearing on cancer. The leading article, "Recent Contributions on the Genetic Concept for the Origin of Cancer—Studies on the Nature of Adaptation of the Transplantable Tumour", is by L. C. Strong; it is 36 pages in length and is illustrated by a graph three feet long (and double sided); it would be necessary to be very enthusiastic to follow Strong through these 36 pages. It is with something akin to relief to find Strong concluding that the whole affair is a little unsatisfactory, for he finally decides . . . "It seems likely that the concept of genic instability is the probable explanation of the irregularities of growth encountered in the study of this transplantable anaplastic carcinoma".

In the same section there is a paper by L. W. Law on "Some Aspects of the Etiology of Leukæmia", part of which is devoted to a discussion of one of the high-lights of experimental cancer to-day, namely, the Gross and the Stewart mouse tumour viruses. At first Law appears to be extremely critical of the Gross findings being interpreted as evidence of a transmissible virus, but after assembling the results accumulated separately by A. Gross, S. Stewart, C. Friend, S. O. Schwartz and A. Graffi, he concludes that . . . "Modification has occurred of an acellular material, obtained from an *AKR* source in serial passage indicating a self-perpetuating characteristic. The bulk of the evidence to date, therefore, would suggest that the acellular materials derived from several sources are leukæmogenic, in certain situations, resembling the capacities of X-rays, estrogens and carcinogens". One is almost tempted to ask, "When is a cancer-producing virus not a virus?" . . . "When it is a leukæmogenic, self-perpetuating acellular material obtained from an *AKR* source in serial passage . . . etc." There seem to be three alternatives, either the agent is a virus, or a chromosomal fragment, or it is infectious ribonucleic acid.

The genetics section also contains a paper by G. Klein of Stockholm on "Variations and Selection in Tumour Cell Populations"; he writes, "It is also being increasingly realized that the change from a normal to a tumour cell is rarely if ever a single step; usually it is the end result of a series of successive changes. Various steps involved in this biological process, part of which is known under the name of tumour progression. . . ."

In fact, whether carcinogenesis occurs in steps or continuously, or how many steps are involved is still a matter of experimental conditions and of interpretation. Klein does not seem to be too sure of his ground (and with very good reason as the whole subject is exceedingly hypothetical), for his conclusions are a study in diffidence; almost every statement is qualified by a saving clause . . . 'some tentative', 'strongly suggest . . . may', 'no reason to assume', 'some evidence', 'little reason', 'seem to be no less complex', 'probably varies from case to case'.

The papers by D. B. Amos, "Some Iso-Antigenic Systems of the Mouse", by S. E. Luria, "Viruses as Determinants of Cellular Functions", and by Fuerst, "Lysogeny", are related to cancer problems, but on a slightly different level as it were.

The article by Sarah E. Stewart, B. E. Eddy and M. F. Stanton, "Induction of Neoplasms in Mice and Other Mammals by a Tumour Agent carried in Tissue Culture", is of particular interest; these workers report that the mouse polyoma virus is also effective in rabbits and hamsters, and in a foreign strain of mice (Swiss) it can induce leukæmia and tumours of the parotid, kidney, thymus, mesothelium, mamma, subcutaneous connective tissue, bone, hair follicle, thyroid, adrenal, buccal mucosa, lung, sweat gland and stomach. Antibodies to the virus could be detected in animals bearing the tumour, in control mice housed in the same environment as mice with the tumour, and in personnel exposed to the virus.

Stewart's results are confirmed in a paper by Mirand and Moore, who also report that the mouse polyoma virus can induce a variety of tumours in the hamster and rat.

D. W. H. Barnes, M. J. Corf, P. O. P. Ilbery, J. Loutit and F. E. Neal propose to treat leukæmia by destroying all the lymphocytes by radiation and re-populating the system with healthy cells; the resulting combination of tissues and cells derived from two individuals is termed a 'chimera'.

The section on the biology of cancer consists of three papers: the first, by L. H. Gray, contains little directly on cancer, except for a cautious statement that "one particular effect of ionizing radiation on genetic material should be mentioned as conceivably of importance in relation to cancer induction, namely, the transformation of prophage into phage". The use of the word 'conceivably' is appropriate here, for it is conceivable that cancer is induced by a virus which conceivably resembles phage. The epilogue to the conference is a paper, "The Biology of Cancer", by the eminent virologist Sir Macfarlane Burnet. He believes that carcinogenic change can be regarded as "almost entirely" due to somatic mutation or clonal selection. As evidence in support of somatic mutation he describes the observations on Australian long-fleeced sheep. In 30 examples of long-fleeced sheep in large herds of short-woolled breeds (20 million sheep), 1 case showed 44 per cent area involvement of the wool, suggesting that the mutation occurred when the sheep consisted of two cells only; 3 cases showed 23 per cent area, indicating mutation at the 4-celled stage, and 15 cases had 0·2–5·6 per cent area, suggesting mutation at a stage later than 16-cell segmentation. The frequency of mutation per cell is calculated to be $10^{-7 \cdot 15}$ to $10^{-7 \cdot 3}$, which is of the same order as mutation for germ cells.

Burnet has thus, apparently, overcome the most serious theoretical difficulty for somatic mutation, namely, that raised by the multicentric view postulating that carcinogenic induction takes place in a whole region of tissue simultaneously and not in a single cell or small group of cells. But to discuss this fascinating problem adequately would require a full-length review on its own.

I. HIEGER

An Introduction to Medical Genetics

By Dr. J. A. Fraser Roberts. Second edition. Pp. x+263. (London and New York: Oxford University Press, 1959.) 35*s*. net.

THE author looks forward to the day when genetic knowledge is so perfectly incorporated into medicine that specialists in medical genetics are no longer needed. The complexities of human biology would seem to make this a distant and perhaps unrealizable future, and it must also be admitted that little positive work has been done in the past to show the clinician or medical student how genetic principles may be put to use in ordinary clinical practice. Recent discoveries relating blood group frequencies to specific diseases have generated a new interest and the present book, a second edition appearing nineteen years after the first, is an admirable introduction to the subject, illustrated exclusively by medical examples and almost wholly deductive and non-mathematical in treatment. It is designed for the clinician or senior student with a real interest in learning something about medical genetics. The point of view is clinical and based on the affected individual: eugenics and the public health are not discussed. The average medical student may well find the book too demanding, but he should nevertheless be made to read the last chapter, on genetic prognosis. Here is a lucid description of how anxious parents can be accurately helped in one of the most critical decisions they will ever have to make, whether to have more, or even any, children. Precise and sometimes extensive knowledge is an essential prerequisite and in this field also the practitioner should know when to call in the specialist.

Very recent advances in human cytogenetics, which it was possible to refer to in a postscript, have already led to spectacular discoveries, and new observations are being reported almost monthly. After sufficient time for their proper digestion a third edition will surely be called for. The opportunity might then be taken to consider how the actions of doctors affect the genetics of the human race and of particular individuals, not only through the mutagenic effect of the medical uses of radiation, and perhaps of drugs, too, but also through the effects of medical treatment in preserving individuals carrying deleterious genes so that they reach the age of marriage and reproduction.

R. H. MOLE

The Reach of Science

By Prof. Henryk Mehlberg. Pp. xii+356. (Toronto: University of Toronto Press; London: Oxford University Press, 1958.) 45*s*. net.

THIS book is an able study in the philosophy of science. If it seems, in part, a little heavy-handed, the reader must accept that as something to be paid for the author's careful approach, and his concern to avoid misunderstandings. There are three main parts: the concept of scientific knowledge, the method of science, and the universality of science. It is a little difficult to state exactly where the writer stands, but he is evidently a liberal upholder of the "logical inherent universality of science" rather than of the rigid positivism stemming from Comte, who, in the event, has not proved a very constructive influence in research.

Prof. Mehlberg makes a good point in bringing under one critical comment both historicism and psychologism. The errors are parallel; in the first case to see in history the sole explanation of something, in the second to assign to subjectivism an excessive share in the unravelling of causes.

The urge to believe that "whatever is knowable is scientifically knowable" is excellent so far as it goes. It is hard to credit nevertheless that the author intends to press his thesis to the limit, in view of countless lives lived both rewardingly and beneficently without so much as a shred of 'knowledge' as thus defined.

F. I. G. RAWLINS

The World of Learning, 1959–60

Tenth edition. Pp. xiii+1221. (London: Europa Publications, Ltd., 1960.) 140*s*. net.

"THE World of Learning" continues in its now established form and hence remains a most valuable comprehensive compilation of academic organizations throughout the world. It includes details of Unesco, giving its origin, aims, functions and activities, and followed by alphabetical treatment of the academic institutes of each of the member countries. It includes learned societies, research institutes, libraries and archives, museums and art galleries, universities, colleges and technical institutes. The entry for each institute contains its address, the names of the leading officials, and in most cases a list of professors is provided. The compilation ends with a thorough sixty-four page index of all the institutes covered. It is regretted, however, that the editors have still not been able to gain the full co-operation of U.S.S.R. institutes, and the total contribution by the U.S.S.R. remains at twenty-eight pages. The work loses some of its usefulness by still not having a name index.

Chemical Process Principles

By Prof. Olaf A. Hougen, Prof. Kenneth M. Watson and Prof. Roland A. Ragatz. Part 2: Thermodynamics. Second edition. Pp. xviii+505–1072+xix–lvi. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 78*s*. net.

THIS is a completely revised edition of a book first published in 1947. After an introductory—but not elementary—chapter on thermodynamic principles, the authors present an extensive chapter on the properties of pure fluids, mainly based on the Lyderson–Greenkorn–Hougen three-parameter modification of the theorem of corresponding states. The rest of the book can be divided into three parts. In the first part the authors discuss the aspects of thermodynamics that are of particular interest to mechanical engineers, such as fluid-flow, power production, propulsion, and refrigeration. The second part is concerned with solutions, vapour-liquid equilibria, and separation processes. The last three chapters deal with chemical equilibria in simple and complex reactions. This edition is enlarged as well as improved. Stress is laid on fundamentals, and it has been skilfully brought up to date. It is a comprehensive work at a level far more advanced than most currently available text-books, and will hold an important place in the university class-room as well as on the reference shelf. If it has a fault, it is that of obscurity, particularly in the first chapter. This is no primer, and the unversed reader will be well advised to choose another book. The informed reader, on the other hand, will find it a valuable addition to his collection.

L. E. MARC DE CHAZAL

EVOLUTIONARY ORIGIN OF SEXUAL DIFFERENTIATION AND THE SEX-RATIO

By DR. H. KALMUS and DR. C. A. B. SMITH
The Galton Laboratory, University College, London

STUDIES of sex ratio usually start from the assumption that it is specifically advantageous for a species to divide itself into two sexes in equal numbers. They then proceed to special explanations why this ratio should break down or be imperfectly realized in particular instances. The purpose of this article is to investigate: (1) why and when a 1 : 1 sex ratio might be advantageous; (2) how it might have arisen.

Advantages of Sexual Differentiation

Experience suggests that inbreeding in a population is usually disadvantageous, and often markedly so. One of the prerequisites for outbreeding is cross-fertilization, and this also provides a large number of different gene permutations through genetic recombination. Such genetical diversity can be important when there are abrupt changes in environmental conditions, and without it the species may not be able to survive. A possible further function of recombination is the replacement of deleterious mutants. Without such replacement, mutants which are only slightly disadvantageous could slowly accumulate by chance in small isolated populations, and in time the species might die out. These three advantages of cross-fertilization suggest why it should be biologically important.

Although it is possible to have cross-fertilization without sexual differentiation (a condition called isogamy), we show in what follows that it is greatly assisted by such differentiation. We suggest that this is the fundamental reason for the evolution of sex in a population, and why it should have arisen repeatedly in the history of a single species.

Fertilization also serves the propagation of a species. Self-fertilization is much simpler and a less-hazardous procedure than cross-fertilization. Hence, unless there is a really effective barrier to self-fertilization, it is likely to be very much more common than crossing, especially in a species which is rare and widely scattered, and this could result in a harmful degree of inbreeding.

There is accordingly a conflict in many species between the advantages of cross-fertilization on one hand, with its avoidance of inbreeding, and self-fertilization or clonal development on the other hand, with their much greater ease of propagation. Survival of the species may depend on some compromise.

Another pair of contradictory tendencies closely connected with our problem are the respective advantages of being large and relatively secure, or of being small, numerous and mobile. In multicellular organisms compromise solutions are reached which combine both these tendencies, either by the sequence in time of large soma and small gametes or spores, or by the simultaneous production of large and small gametes in the same species.

Advantages of Numerical Sex-Equality

One aspect of such developments is the establishment of certain numerical equilibria, of which, as we shall show, the sex-ratio is an example. Let us start by considering a situation in which cross-fertilization is guaranteed by self-sterility. For example, in many unicellular species two gametes from the same clone cannot unite to form zygotes, but those from different sub-strains may be able to do so even when they are alike in outward appearance. If there are only two such sub-strains, suppose they occur with respective numbers n_1 and n_2: then the number of opportunities of such a mating is proportional to the number of pairs of individuals chosen one from the one strain and one from the other, and this number is n_1n_2. Now if the total number of individuals $(n_1 + n_2)$ is assumed to be effectively determined by environmental conditions, we (will) get maximum propagation when n_1n_2 has its maximum value for given $(n_1 + n_2)$. But:

$$n_1n_2 = \tfrac{1}{4}(n_1+n_2)^2 - \tfrac{1}{4}(n_1 - n_2)^2$$

and hence n_1n_2 is greatest when $\frac{1}{4}(n_1 - n_2)^2$ is least, that is, when $n_1 - n_2 = 0$, and the two sub-strains occur in equal numbers. (Similarly, with any number of sub-strains which are cross-fertile but self-sterile, the optimal situation is that in which all strains occur in equal proportions.) Mechanisms which ensure numerical equality of the two kinds of gametes will therefore confer a selective advantage: and we may expect in such cases numerical equality of morphologically similar types of gametes. Situations of this kind are observed among other cases in green flagellates (Klebs[1]) and also in the infusoria (Sonneborn[2]) where nuclei are exchanged between two mating types.

The products of isogamy in algae and of conjugation in infusoria do not undergo long and complex developmental changes and therefore do not need much reserve substances. On the other hand, such substances occur more or less abundantly in the zygotes of many higher plants and animals. If such species also require a high degree of genetical recombination, and hence cross-fertilization, the maximum propagation will be achieved by providing the greatest possible number of zygotes with sufficient reserves. Kalmus[3] has shown that under certain plausible conditions this will happen if there is an unequal distribution of reserve material to two different kinds ('small' and 'large') of mobile aquatic gametes, but in such a way that the reserve as a whole is about equally divided between a large number of the small gametes and a small number of the large ones. In organisms having external fertilization, such as echinoderms, bivalves, fish and others, the total masses of spermatozoa and ova are indeed found to be approximately equal. A similar situation is the comparable bulk of pollen and ovarial material in some wind-pollinated plants.

In monœcious plants and hermaphroditic animals the proportion of sperm and ova (pollen and ovules) is regulated by physiological means in each individual, and questions of sex ratio do not arise. The problem is somewhat different in bisexual animals and plants where the proportion of sperms and ova depends on the ratio of males to females in the population. The assimilatory powers of males and females are not very different in many species, and each can produce about the same volume of sex products. Therefore the optimal situation of near equality of bulk of spermatozoa and ova can be safeguarded by near equality of the numbers of individuals in the two sexes[3]. This occurs in non-copulating species of the following animal groups: Coelenterata, Scolecida, Mollusca, Brachiopoda, Enteropneusta, Echinodermata, Tunicata, Ascidia, Cyclostomata, Pisces and Amphibia. In plants, comparable relations exist among Myxomycetes, Phycomycetes as well as among the diœcious flowering plants.

In the case of animals with internal fertilization which have two sexes (copulating, gonochoristic forms) we shall require the chances of encounter of a male and female to be a maximum; we have already shown that this occurs when the two sexes have equal frequencies, assuming the total numbers to be limited by other factors.

Inequality in the numbers of the sexes can also be disadvantageous in another way. If the population contains, let us say, only a small number of females, then half the genes in the next generation must be derived from these females, however many males there may be. It follows that the genetical diversity of the population will thereby be restricted; in fact, there will be a large number of pairs of half-sibs in the next generation, and so presumably a large number of matings of related individuals: and this will lead to inbreeding. Sewall Wright has devised a measure of this restriction of genetical variation in a small population which he calls the 'effective size' of the population. If there are n_1 males and n_2 females, and the population breeds at random, the effective size is[4]:

$$N = \frac{4n_1n_2}{n_1 + n_1} = n_1 + n_2 - \frac{(n_1 - n_2)^2}{n_1 + n_2}$$

The greater the 'effective size' the smaller the degree of inbreeding, other things being equal; hence the optimal situation occurs when the effective size N is a maximum. For a given total size $n_1 + n_2$ this will occur when $(n_1 - n_2)^2$ is least, that is, when $n_1 = n_2$, and there is a 1 : 1 sex ratio. This effect will be most important in small populations, for example, if a species is divided up into small, relatively isolated groups.

In all situations considered above we see that the observed sex-ratios show a general agreement with those expected on the theory that the function of sex is to reduce inbreeding so far as possible. In the case of species which rear their young, a further reason for expecting equality of sex-ratio at the time of sexual maturity has been given by Fisher[5] in terms of the effort required to raise offspring of the two sexes.

Evolution of the Sexual Differentiation

We now turn from the consideration of the final population sex-ratio to the mechanisms through which sexual diversity and the numerical equality of the sexes may have evolved. A survey of the animal[6] and plant[7] kingdoms shows that sex-differentiation has vanished and probably arisen many times during evolution, and it is safe to assume that no two instances were quite the same. Let us again assume that a species requires the fusion of two genetically diverse types of gametes for its continued existence, and that fertilization will be most successful if the reserve material is stored mainly in one type[3]. Some barrier is required to prevent gametes from the same individual from combining, and this must be powerful, or it will be frustrated by the much greater probability of encounter of such gametes as compared with those from different individuals. Three possible devices are as follows: (1) Self-sterility mechanisms, for example, self-incompatibility. These are sometimes rather precarious arrangements, found in fungi, other plants and a few animals. (2) Proterandry or protogyny, where individuals produce male and female sex products at different times in succession. (3) The differentiation of two types (males and females), one producing small gametes, the other large ones.

In certain fish[8] and mosquitoes[9] single allelic differences or possibly short regions in a chromosome seem to determine sex. In most other organisms which have been investigated there have evolved different and more complex schemes of genetical sex-determination[6]. One difficulty which such mechanisms encounter during their evolution is that of apportioning three genotypes AA, Aa and aa to two sexes with equal frequency.

One theoretical possibility would be to have both homozygotes AA and aa of one sex, and the heterozygote Aa of the other sex. This has not been found, although Whiting and Whiting[10] discovered a somewhat similar mechanism of sex determination in the hymenopteran *Habrobracon judlandis*; there, heterozygosity at a number of loci on different chromosomes results in female development. Males are normally haploid, but can also be produced by homozygosity at some of these loci.

Another possibility is that of a homogametic sex, genetically aa, and a heterogametic sex, Aa; in this context A, a can denote either allelic genes or complete chromosomes (Y and X). This kind of sex determination is of frequent occurrence. It could arise through the gradual elimination of the type AA.

Let us suppose that in a diploid population homozygous for gene a, and producing only small gametes, there arises a dominant gene A which results in larger gametes with more reserve material being formed. These gametes which will carry A will thus provide the zygotes with more reserves, and thus be advantageous; hence the gene A may be expected to spread through the population. This spread will, however, be checked by the difficulty of union between these large, relatively static gametes, so that the advantage will only remain while there are a sufficient number of small gametes also present. Hence this situation may be expected to lead to an equilibrium in which both dominant and recessive types persist, and most fertile unions are between large and small gametes. From such a mating system in which there is already a tendency towards sexual differentiation, natural selection may be expected to develop a more complete sexuality in the course of time.

Another conceivable origin of sex-differentiation would be the appearance of a dominant mutation A with the property that types AA and Aa produce large gametes, and aa produces small gametes. Let us further suppose that there is dissortative mating, that is, a preference for the mating types dominant × recessive rather than dominant × dominant or recessive × recessive. Then the calculations of Li[4] suggest that even with only a moderate degree of dissortation, the population will approach an equilibrium in which the proportions of dominants and recessives are equal, and only a small proportion of the dominants are homozygotes *AA*. Now the structure of such a population differs only little from one with completely dissortative mating, with only the two types *Aa*, *aa*, present in equal numbers and only the single type of mating *Aa* × *aa*. This in turn suggests that it may be comparatively easy for selection to change from moderate to complete dissortation; this involves little disturbance to the population as a whole, but provides it with the advantages of sexual differentiation.

It seems worth noting, as pointed out to us by Prof. L. S. Penrose, that a dissortative mating can lead to an equilibrium also when the homozygote *AA* is lethal, whereas without dissortative mating this would lead to a gradual elimination of the gene *A*. If, therefore, a dissortative mating system arises during the development of sexual differentiation, it becomes possible for the *AA* type to tend to lethality without destroying the system, thus emphasizing the differentiation into the two types *Aa* and *aa*. This can lead ultimately to situations like the human one, in which the *YY* chromosomal zygote is presumably lethal.

Other mechanisms of ensuring numerical equality of the sexes are of course conceivable. It should, however, be pointed out that most of the tendencies which have been postulated in this article do not apply to the primary sex ratio, but to numerical sex equality at maturity. It has been frequently claimed but also denied that the primary sex ratio, that is the sex-ratio at conception in man, is very high and it is a fact that the secondary sex-ratio, namely, that at birth, shows regularly a significant excess of males[11]. However, the survival of females is greater through most of post-embryonic life and women reach a higher age than men. This situation results in near equality of the sexes during the reproductive ages.

BIOLOGICAL EQUILIBRIA IN HUMAN CANCER

By DR. KENNETH W. STARR, C.M.G., O.B.E.
Hon. Director, New South Wales State Cancer Council

NO human race is immune from cancer and the cancerous spectrum is encountered variously in all populations. Humanity justifiably regards the disease with dread because of the insufferable pain and abject dilapidation which attend its fierce mortality. Several unfashionable studies[1–5] have established the fact that most patients who contract the disease eventually die from it, and Lancaster[6] avers dramatically that in the younger age-group in Australia there has been no improvement for more than a hundred years; in fact, some deterioration has occurred in melanoma and leukæmia. The disease therefore is "no ballet dance of bloodless categories" but a poignant human problem.

It may be remarked with disaffection that a perceptible estrangement exists between the experimental and clinical disciplines in oncology. Experimental science finds difficulty in disciplining the uncontrollable variables of the human patient, and studies in man are notably disconcerting and imprecise. Accordingly, scientists dispose for their purposes of a vast array of susceptible animal colonies and artificial carcinogens with which, by exogenous administration, tumours are induced and transplanted. In this fashion, the honoured tradition of Percival Pott[7] and of Yamigawa and Itchikawa[8] is projected into modern cancer research. It is then assumed that the tumours studied by these "exquisite techniques, masterfully applied" are comparable in genesis, evolution, and pathology with human cancer. This assumption requires examination.

With regard to carcinogenesis, the scientist (Peyton Rous[9]) declaims: "Now we know that neoplastic changes are not spontaneous, but are induced by extraneous agents and conditions in the generality of instances and almost certainly in them all. It has become 'rule of thumb' on finding a tumour to look for the agent bringing it on". To the clinician, such an attitude is not only unacceptable, it is also unintelligible. With the exception of a few solar and industrial cancers, the only "rule of thumb" applicable to the lethal cancers which he daily treats is his uniform and unmitigated ignorance of their ætiology.

Most experimental carcinogens are mutagenic, and the clinician is further asked to believe that human cancer results from a somatic mutation. Consequently, "there is little ground for optimism about cancer" and "we should look forward not only to failure but to a sharp increase in the incidence of the disease"[10]. Ignoring the threnody, it may be observed that cancer rates, cancer predilection for both organ and site unrelated to mass, and cancer behaviour cause difficulties for this hypothesis. Recognized mutation rates in human populations rarely exceed 1 per 10,000 of population, while cancer attains a much higher rate (further augmented by unrecorded 'silent' and precancerous complements). Cancers in man favour certain zones of certain organs comprising about 20 per cent of the body mass while ignoring adjacent zones and other massive tissues (the voluntary muscles, bones, liver and small gut are rare sites). Certain systems (especially the alimentary) produce about 5 per cent of multiple tumours. Cancer of the female breast shows several anomalies. It is slowly increasing in this century[11], shows hereditary associations[12], is bilateral in 3 per cent of patients, is consistently more frequent on the left side, and in almost half the cases affects the upper and outer quadrant[13]. The theory of somatic mutation is unsatisfying when confronted with the combination of site and organ predilection unrelated to mass, bilaterality, laterality, multiplicity and variable frequency. An alternative genetic hypothesis appears essential.

From their studies of spontaneous carcinogenesis in human explants, Levan and Biesele[14] have postulated chromosome fracture in a tissue of high mitotic index. The human small gut is 23 ft. in length, and is remarkable for its very high mitotic index and nucleoprotein turnover. Cancer, however, is practically unknown there.

Steiner[15,16], in his superb surveys, finds several incompatibilities. He contrasts the long latent period and independent stages of human cancer with the more rapid appearance of cancer following chemical and other mutagenic carcinogenesis. He notes, too, that many phenomena of experimental carcinogenesis are absent in human cancer (cocarcinogenesis, summation, synergism, inhibition, conditional carcinogenesis, and anticarcinogenesis by noncarcinogenic substances). Further, he marks the following cancers as essentially human in character because they have no counterparts in type and behaviour among the induced tumours of animals: cancers of the stomach, colon, rectum, pancreas, lung (bronchogenic), œsophagus, uterus, salivary gland and breast ("a different disease"). This list comprises the majority of cancers which the clinician encounters.

Spontaneous human and animal cancers are notably resistant to chemotherapy, effective against experimental cancers[17]. The elimination of industrial cancers—a great triumph of modern preventive medicine—has not affected total cancer incidence because known carcinogens are rare clinically. To all these considerations, Greene's[18] experience in the transplantation of human tumours is complementary—"the highly individualised primary neoplasm develops to attain 'independence' and then to transcend the species barrier. This profound biological transformation is not due to sudden mutations affecting normal cells but to a developmental process". Willis[11] agrees with this.

The complexity of the genesis and evolution of human cancer becomes even more apparent when the biological equilibria in which it is involved with other vital processes are studied.

The Genetic Equilibrium

"It must be difficult always to remember", wrote Darwin in his "Origin of Species", "that the increase of every creature is constantly being checked by unperceived hostile agencies". Although modern science has increased the life-span, death comes as it must to all men, chiefly through disease. The pattern of disease varies in each population. In oncology the Mendelian population is chiefly racial, for it is found that certain races favour certain cancers and shun others. The cancer-rates, too, vary among the races; low rates are chiefly found among primitive races—the less-variable wild organism (Waddington)—and high rates in advanced cultures. It is a genetic truism that these Mendelian populations with "the common gene pool" (Dobzhansky) and "an exceedingly heterogenous aggregate of largely heterozygous genotypes"[19] survive by virtue of their heterogeneity. Moreover, this heterogeneity is not related to single genes but to "polygenic groups" mutually involved in a "totality of interaction" (Dubinin).

In 1825, Benjamin Gompertz[20], of Northampton and of Portuguese extraction, presented a communication before the Royal Society asserting that the "force of mortality" and the age of human populations manifested a straight-line relationship in the logarithmic graph. This function has been merely of academic interest for more than a century, and its current resurrection in relation to human cancer is indeed a scientific romance. It has now been sufficiently demonstrated in countless millions of human beings in many populations that the Gompertz function is valid[5]. The simplicity of this two-dimensional graph is startling considering its import, and it has recently been shown that it is maintained before adulthood, if violent deaths are excluded[21]. The force and authenticity of this human demographic study is in some contrast with the restricted information from population studies in animals which "vary according to strain, sex, laboratory conditions and numerous other factors. The number of animals, too, is usually too small to provide good curves"[21].

When cancer mortality is plotted against age in the logarithmic graph it is found that a straight-line relationship is sustained at a higher intensity and the Gompertz function is applicable[4,5,22–25]. At any age, therefore, the cancer mortality is a function of total mortality, and the exponential processes are in equilibrium[5].

The gradient of the exponential graph for total mortality shows a doubling rate each 7–8·5 years, a specific character of the human species and therefore genetically determined. Strong genetic influences consequently subtend the genesis, evolution and consummation of human cancer. The number of cancer deaths in these surveys exceeds 15 millions, and it is accordingly difficult to understand why these telling facts do not dominate all cancer research.

With the possible exception of leukæmia, the straight-line behaviour of the cancerous sub-population relative to the Gompertz function is incompatible with the virus theory of cancer[25]. This casts some doubt on Stanley's zealous asseveration—"it is difficult to escape the conclusion that viruses may be the ætiological agent for most, if not all, cancer, including cancer in man, and represents by far the most intellectually satisfying hypothesis consistent with the presently known facts"[26]. The function emphasizes the genetic relationships of human cancer and creates considerable difficulties for any hypothesis based on exogenous carcinogenesis.

The Pathological Equilibrium

Each Mendelian population in man manifests its own disease-pattern, and some of the component diseases obey the Gompertz function. The pattern appears to be determined early in life[5], and accordingly has strong genetic affinities. Cardiovascular degeneration is so widely encountered in clinical experience that it is regarded as an 'average' disease within this pattern.

The process of neoplasia produces benign lesions (such as nævi, universal in whites), border-line lesions (which may behave in either a benign or a malignant fashion), 'silent' and 'histological' lesions discovered post-mortem or microscopically, and finally malignant lesions distinguished for their lethality. Moreover, certain diatheses (diabetes mellitus) are associated with a higher cancer incidence. Cancer, too, is a complication of certain components of the disease-pattern (gastric ulcer, ulcerative colitis, achlorhydria, megalocytic anæmia, etc.). 'Silent' or histological cancers are being reported with increasing frequency, especially in the thyroid, bronchus and prostate. In the last-named instance it is asserted that 'histological cancer' can be demonstrated in more than half of all patients dying after eighty years of age.

While neoplasia therefore is an 'average' disease of the population, cancer is not. Moreover, Hardin Jones[5] finds that total disease and cancer incidence are interrelated, and he emphasizes the narrow margin of variation in the "threshold of manifestation" (Law) of cancer compared with the wide margin in 'average' diseases. The intensity of the age-specific mortality of cancer equals that of the senile population of more than seventy years of age. From these points of view it is evident that the cancerous sub-populations of the various races resemble each other more than their parent populations[5], and the behaviour of these sub-populations is comparable with that of a new biological species[27].

Despite the manifold sources from which the cancerous sub-population may be recruited, it is a remarkable fact that the cancer mortality in any population is predictable, fairly constant and varies within narrow limits. Reference to the year-books of the various nations (and since 1952 to the "Demographic Year Book" of the United Nations) will reveal that the cancerous sub-population is a fairly constant proportion of the parent population. Deaths from cancer vary between 0·03 and 0·3 per cent, the higher rates being encountered where superior public health services prevail. In this regard the Commonwealth Statistician records[28] that in Australia "there has been no increase in cancer mortality since 1921 and in some age groups it has actually declined". Soper[29] refers to a similar state in Switzerland. The manner in which this constant and distinctive biological group of lethal cancers is 'selected' from the neoplastic spectrum and disease-pattern of the parent race, strongly suggests Darwinian natural selection, operating in a Mendelian population.

The Ontogenetic Equilibrium

The paucity of induced tumours available for experimental study is in some contrast with the bewildering array and variable frequencies of human cancers. Moreover, subtle nuances of malignancy are encountered varying from 'histological' cancer with metastases but benign behaviour (papillary cystadenocarcinoma of the thyroid gland) to lethal malignancy without a detectable primary (melanoma malignum) or without metastases (glioblastoma multiforme). Willis[11] holds the view that this protean character of cancer demolishes the theory of somatic mutation. It is likely, too, that failure to appreciate these aspects of clinical cancer may explain the tendency in the scientific literature to regard cancer as a generic disease differing from the normal only in a single enzymic or other biochemical aberration and eradicable by a single chemotherapeutic nostrum.

Nevertheless, apart from occasional morphological and behaviouristic difficulties, the basis of orderly taxonomy in histopathology is genetic (histogenesis)[11].

Human cancers do not occur uniformly in equal numbers and similar types during each year of the life-span. Some cancers are very frequent, others rare. In populations under the action of natural selection, organisms tend to cluster about mean values for all characters[19]. A similar phenomenon is discerned as a peak incidence of various groups of cancer at certain ages. When such a chart is prepared (Fig. 1) it is apparent that the physiological epochs (childhood, adolescence, maturity, menopause, senescence and especially puberty) are also involved in these incidences. Thus the "threshold of cancer manifestation" may be related to the "ontogenetic differentiation"[33] of the host.

The racial phenotype is the distinctive characteristic of Mendelian populations in man and is profoundly influenced by both hereditary and environmental (including cultural) factors. In the same fashion, the physiological development of the host modified by environment appears to modulate the clinical presentation of human cancers, and considerable racial variations are observed.

Thus, heredity manifests itself in hereditary cancers, 'cancer families', cancer diatheses, and certain pathological symbioses (such as the association of stomach cancer with achlorhydria, megalocytic anæmia, certain blood groups, and a genodermatosis, acanthosis nigricans). Cancer afflicts the sexes equally, and sex has a profound effect not only on the cancer of the reproductive organs but also in an unexplained fashion on certain somatic cancers (bronchogenic carcinoma, pharyngeal cancer). On the other hand, monozygotic twins do not manifest total concordance, just as the frequency of similarity is not identical in mono- and dizygotic twins (Gorer and Oliver[30]). Migrant studies, too, confirm this blending of hereditary and environmental factors. These studies (for example, the African Negro in the Americas), while never conclusive, suggest that cancers of the parent population first predominate, being supplanted in succeeding generations by indigenous cancers, and do not recur (a Lamarckian twist).

In 1927, the Registrar-General of the United Kingdom[31] reported the relationship of various cancers to occupation and social stratum and similar studies have since incorporated geographical, edaphic, social (marriage, housing, diet, etc.), and personal (obesity, hygiene, pregnancy, etc.) influences.

Another aspect of human cancer emphasized by the peak incidences is that the clinical appearance of the cancer is an index of the duration of the latent period. It will be noted that certain cancers do not appear in certain decades (for example, carcinomata of the stomach, colon, and rectum never appear before the tenth year, those of the breast and pancreas never before the twentieth year, and those of the prostate, gall-bladder and mouth rarely before the thirtieth year)[14]. The 'scatter' of the age incidence is less marked too at the extremes of life (in childhood, the nephroblastoma, neuroblastoma, embryoma and leukæmia, and in the aged, œsophageal and prostatic cancer). The cancers of these latter epochs are characteristic exanthems. It appears, therefore, that the latent period is a fairly stable cycle in human cancer. This suggestion is supported by Strong's[32] studies in mouse populations on the compensatory responses evoked by fluctuations in the maternal age, litter size and latent period. So stable is the latter characteristic that homœostasis was only restored to the biological equilibrium by the development of new cancers in different organs, the total cancer incidence remaining constant.

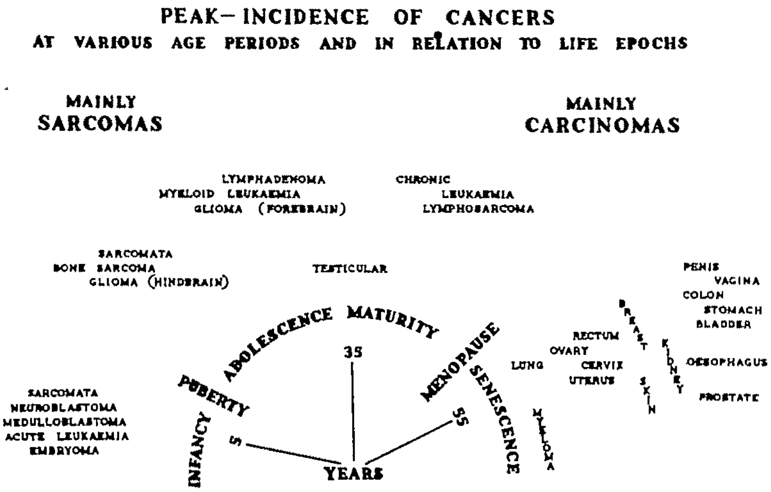

Fig. 1. Peak incidences of human cancers charted against age and physiological epochs (data from Potter's "Pathology of the Fœtus and Newborn" and Harnett's "Cancer Survey of London")

In this equilibrium between the ontogeny of the host and the manifestation and behaviour of human cancer, an oncological paraphrase of Loeb's law[33] may be discerned: "the human organism, its constituent parts and their associated cancers each has its own characteristic time-curve".

The Oncological Equilibrium

An equilibrium of the fourth order exists among the cancers themselves. Mendelian populations under the action of natural selection compensate extreme deviations of one trait with some form of deviation of another[19,34]. The cancers themselves behave in this fashion, and the equilibrium is of considerable epidemiological and demographic interest. If fluctuations occur in the frequency of certain cancers, homœostasis is then achieved by compensatory fluctuations in the frequency of other cancers.

It is now twenty years since Cramer[35] published his law: "There appears to be a general law, that when in a given population the incidence of cancer in any one particular organ is markedly increased when compared with another, there is then a compensatory decrease in the incidence in a number of other organs".

In 1909, the Registrar-General of the United Kingdom directed attention to the catastrophic increase in males, since 1870, of cancer of the tongue (228 per cent). Contemporary clinical opinion held that unless radical measures to curtail tobacco smoking were enforced, a further increase among males and females could be expected to reach a maximum by 1950[36]. Of course, despite increased tobacco consumption, the incidence of tongue cancer is now halved. To-day, clinicians are deeply concerned with the avalanche of bronchogenic carcinoma in males and tobacco is again under criticism. Case[37] has used cohort analysis to show that in the United Kingdom, coincident with this marked increase in lung cancer, a compensatory fall in several other cancers (especially oropharyngeal) has occurred.

The Clinical Equilibrium

This equilibrium is a further manifestation of the cancer-host relationship. It is of paramount importance to the clinician and to the research worker, who believes with Homburger that "at the core of the cancer problem is the patient afflicted with the disease". It is the clinico-pathological equilibrium known as 'latency' or 'dormancy'.

In most cases the appearance of a cancer is a prelude to a continuously disturbed equilibrium in favour of the cancer until the host dies. This is not always the case. Rarely the equilibrium is disturbed in favour of the host and the tumour spontaneously regresses or disappears (notably melanoma malignum, retinoblastoma, neuroblastoma, choriocarcinoma testis, myosarcoma uteri and certain angiomata and hepatomata). Quite frequently encountered is an equilibrium of considerable stability. Every clinician is familiar with the patient who, having had a cancer of a certain organ (often the breast) removed one or more decades previously, now has a metastasis in a remote organ. Periods of 10–30 years are far from uncommon. Many observers have reported the circumstances which may suddenly upset this latter equilibrium, to result in cancerous recrudescence and death. Thus surgical operations, pregnancy, illness and accidents[38] are all known to be involved. Many forms of therapy in autonomous cancer achieve temporary benefit until homœostasis invalidates them. However, the symptomless state of latency is obviously a therapeutic goal.

This equilibrium also presents certain distinctive human features having no counterpart in experimental oncology. This difference relates to the decay of the afflicted sub-population. In animal studies the death-rate augments as the disease progresses and cancerous tissue preponderates in the body mass. The human patient may perish, however, with a relatively small tumour from metastatic, mechanical, or metabolic complications. The mode of decay here shows a straight-line relationship between the logarithmic scale of survival and the linear measure of time-duration of the disease. "It is a remarkable fact that the death-rate for all kinds of human cancer remains nearly fixed from the moment when the cancer is identified"[5]. Consequently, the termination of human cancer is no fortuitous affair but the orderly decay of a biological process from "unperceived hostile agencies".

Biology of Human Cancer

Cancer is usually represented as an anarchic and disorderly process, but Darwinian and Mendelian regulation permeates its biology and the Gompertz function is its commandment. Intricate biological equilibria, rising to the fifth order, ensure its specific integrity, the ratio and longevity of its constituent lesions, its inexorable autonomy and constant lethality.

Heterogeneity is the vital elixir of Mendelian populations under the action of natural selection. Cancer is the lethal element in the neoplastic component of the disease-pattern, and consequently is an appanage of that heterogeneity.

From these points of view, the cancerous patient is a phenodeviant in antagonistic symbiosis with a lethal parasite. This processional system emerges from the anlagen of the embryo, and after a variable latent period crosses the thresholds of manifestation and autonomy to encompass the death of the host. Throughout its course the cancer is embedded in a reticulum of biological equilibria, genetic and environmental pressures, and homœostatic reactions. The resultant of these forces determines the number, site, nature and behaviour of the lesions.

It is apparent that experimental and clinical cancer are not identical diseases. The principal divarication between the oncological disciplines pertains to carcinogenesis. The genesis of experimental cancer is mainly exogenous and mutagenic, and a 'cause' is specified. Human cancer, on the other hand, arises in a complex genetic phenomenon and evolves with the ontogeny of the host. No 'cause' can be postulated until the physiology of gene action and of normal ontogeny have been reduced to precise physicochemical terms (Lerner).

The "Novum Organum" (LXXXI) lays it down that "it is not possible to run a course aright when the goal itself has not been rightly placed". The prevention of human cancer is probably eugenic, but neither science nor society can yet confront and assimilate this proposal. The goals in contemporary clinical oncology are therefore readily defined if the present cure-rate is to be augmented. First, to devise a test which will distinguish the cancerous sub-population and permit the cure of their precancerous and cancerous lesions before autonomy supervenes. Second, to reduce ineradicable autonomous cancer to 'latency'.

These proposals demand novel studies in human metabolism; but there is some evidence to show that they are now within the ambit of modern scientific techniques. Success in this ambition would suppress this *genius ater* which pervades society and rob cancer of its terrors.

A FORERUNNER OF TWENTIETH CENTURY PHYSICS

A RE-VIEW OF LARMOR'S "AETHER AND MATTER"

By LANCELOT LAW WHYTE

IN 1900 there appeared a work which, though little read to-day, is of considerable retrospective interest, for it records the ideas of a brilliant theoretical physicist immediately prior to Planck's discovery of the quantum constant and Einstein's formulation of the special theory of relativity.

"Aether and Matter", by Joseph Larmor, F.R.S. (1857–1942, later Sir Joseph Larmor, member of Parliament, Lucasian professor of mathematics at Cambridge, 1903–32) was issued by the Cambridge University Press as an Adams Prize Essay. A thousand copies were printed, which were sold by 1912. It has never been re-printed or translated, and is now rare; I purchased a damaged copy in 1921 for 3*s*. 6*d*. and another in 1953 for £1 10*s*. 0*d*. The most important references to the book are in the original reviews, the obituary notices at Larmor's death in 1942, and Whittaker's "History of the Theories of Aether and Electricity" (2 vols. 1951, 1953), where there are twenty-six references to Larmor, including six to "Aether and Matter".

The full title of the book reads: "Aether and Matter, a Development of the Dynamical Relations of the Aether to Material Systems on the Basis of the Atomic Constitution of Matter, including a Discussion of the Influence of the Earth's Motion on Optical Phenomena". The book is a study of the relations of micro-discontinuity to macro-continuity, of atomic matter to the electromagnetic aether, on a classical pre-1900 basis. The text was written by 1898, but parts of it had already been published in the *Phil. Trans. Roy. Soc.* and elsewhere between 1894 and 1897. Thus the ideas expressed in it were formulated some years before the decisive discoveries which opened the quantum and relativity physics of our century. "Aether and Matter" expresses the point of view of an able mind taking advantage of the facts and theories as at 1894/98.

It is not surprising that Larmor's book has been forgotten. Though Larmor was a profound thinker, he never achieved any outstanding basic result and his work had relatively little influence on the advance of fundamental theory. Much of what was most useful in "Aether and Matter" (the 'Larmor rotation', and other contributions to electron theory) had already been published elsewhere, and by 1905 it was largely out of date, owing to the work of Lorentz, Planck and Einstein. Moreover, Larmor's careful study of the historical development of his subject, leaving none of its difficulties concealed, makes heavy reading for those who have benefited by the clarifications achieved since. Even the best minds have found "Aether and Matter" indigestible; though Bohr took from it the 'Larmor rotation', which he made famous by applying it to quantized electron orbits[1].

None the less, parts of the book are fascinating, for both historical and contemporary reasons. First, he gives a masterly analysis of the history of ideas[2] relating atomic matter to the macroscopic electric continuum; and secondly, he shows (though he did not know this himself) how far his mind could reach out towards issues which are still obscure sixty years later, on the basis of the facts and theories of 1898 daringly interpreted in terms of fundamental physical ideas. This second aspect is the one with which I am here concerned: "Aether and Matter" as evidence that a perceptive application of basic ideas can point beyond established theories.

There is no need to describe the facts and theories of 1898. The fundamental ideas which Larmor employed in interpreting them can conveniently be expressed in five antitheses: atomic discontinuity/macroscopic continuity, matter/electricity, scale-fixed molecules/scale-free similarity in the macro-realm, chiral/non-chiral phenomena, and reversibility/irreversibility. By using these ideas to analyse the physics of the time, Larmor was led to identify the following issues, and to make comments on them which are still valid: the need for a characteristic length providing definiteness of scale in atomic theory; the existence of pure numbers of importance for fundamental theory; the role of chiral properties; the compatibility of molecular indeterminacy with molar determinacy.

It is the fact that Larmor could use basic principles to see so far ahead that has led me back to "Aether and Matter" many times during the thirty years since these same pure numbers and the presence of natural lengths in atomic theory began to receive widespread attention. For while in 1960 we tend to consider these issues in terms of the characteristic discoveries of the twentieth century (Planck's constant, relativistic invariance, quantized fields, new particles, etc.) in 1900 Larmor reached them from very general considerations, which in some sense may lie deeper. Thus something can be learnt from his achievement in recognizing the importance of these four issues.

I will now consider each of them in turn.

Need for Definiteness of Scale

Larmor was the first[3], known to me, to enunciate (pp. 189/193) the principle that to account for the definiteness of scale of material bodies and of their radiations atomic theory must contain at least one constant with the dimensions of a length, or the equivalent. These are not his words, but they express his idea. (Eddington, in his "Fundamental Theory", 1946, p. 16, called such systems 'scale-fixed', as against the scale-free systems lacking any such length.) Larmor regarded this necessity for scale-fixed atomic expressions as one aspect of the more general problem of reconciling the discreteness of material structure with the continuity of fields, which was the main theme of his book. For convenience I shall call the above recognition 'Larmor's principle'.

He used the method of dynamical similarity to show that the use of point electrons and electric actions depending only on e^2/m (for example, not on velocities) led to a "deficiency of definite scale", any steady system of such electrons being alterable to any other linear scale, in accordance with the similarity property of all scale-free systems[*]. But "this indefiniteness of linear scale in a material body cannot exist". Larmor reasoned that this indefiniteness might be eliminated in various ways, by introducing into the laws (*a*) a finite size of the electron; (*b*) other residual terms important at small distances; or (*c*) actions dependent on electron velocities—all of which methods are now in use in relativistic theories, though they may not be directly relevant to the structure of material bodies.

He did not anticipate the main scale-fixing method which proved necessary: the introduction of a new constant h, representing discreteness of action or angular momentum, which yielded two classes of scale-fixing constants: (*a*) in combination with $(k.T)$ and c, a statistically unique wave-length λ_m, which is a function of the temperature, through the use of the dimensionless group $(hc/\lambda k.T)$; and (*b*) in combination with e^2, m and c, a series of basic lengths, defining (with numerical factors) the scale of atoms, molecules, and characteristic optical and other wave-lengths.

Yet the fact that Larmor did not anticipate the dimensions of the necessary constant does not lessen the interest of his principle that a scale-fixing constant absent in 1898 is indispensable. For both relativity theory (by employing combinations with c, for example, e^2/mc^2) and quantum theory (by introducing h and powers of the fine-structure constant) have 'incidentally'—as we may think—achieved precisely what Larmor asserted was necessary[4]. Both theories introduced scale-fixing natural lengths into fundamental theory, and all the empirical data by which these theories are supported represent scale-fixed phenomena. All the quantum and the relativistic modifications of classical theories are necessarily scale-fixed, since by combining either h or c with the 'classical' constants GM, e, m, natural lengths are introduced into the laws.

Thus in a special, but instructive sense, Larmor might be called the unconscious father of twentieth-century physics. For Larmor did not know in what manner his principle would be satisfied, nor apparently did either Planck or Einstein know (for they never referred to this interesting fact) that the two theories they had initiated both satisfied a single principle formulated by Larmor: that fundamental theory must be scale-fixed. Indeed, twentieth-century physics has 'out-Larmor-ed Larmor'. He said: introduce a scale-fixing length. Physics has done this not once, but many times: by discovering h, by employing relativistic corrections, and finally by discovering particles to which a series of theoretically arbitrary masses have to be ascribed in order to fix the linear scale of their respective fields and orbits. So the question arises: Why does contemporary fundamental theory employ not merely the one length that is necessary but very many, the ratios of which are (*a*) powers of the fine-structure constant, and (*b*) the pure numbers relating the mass spectrum of the elementary particles? This leads us to the next point.

---

[*] The following notation is used: e, electron charge; m, electron mass; M, proton mass; c, velocity of light; h, Planck's constant; G, gravitational constant; K, Boltzmann's constant; T, absolute temperature. Also V_e, characteristic electron velocities in atoms; L_a, diameter of any atom or molecule; λ, wave-length of any characteristic optical radiation; λ_m, wave-length of the maximum in the black-body radiation law; α, fine-structure constant.

Fundamental Pure Numbers

It has been clear to most, from Newton onwards, that physics is primarily concerned with numerical ratios, and Larmor's interest in the dimensional aspects of fundamental theory, including the known existence of certain universal constants (e^2, m, c, G) and the suspected existence of others (mass of positive particle, characteristic electron velocities in atoms), led him to a remarkable achievement: the identification of what are to-day recognized as functions of three fundamental pure numbers: (1) the fine-structure constant; (2) the ratio electron/proton mass; (3) the ratio gravitational/electric actions.

Larmor did not, of course, anticipate all the fundamental pure numbers now known, such as those of the particle mass spectrum, the ratios of the lives of the particles discovered since 1932, or those arising in nuclear and high-energy systems. But he identified, and used in arguments which are still valid, functions of the above three numbers ten years before Einstein (1909) directed attention to the importance of the dimensionless group e^2/hc, and twenty-five years before many workers—Eddington, Dirac, Milne, Jordan, and others—took up the study of these fundamental empirical numbers (1925 onwards). This achievement deserves attention, not only for the sake of justice and the historical record, but also because of the challenging question which arises in one case: How could Larmor identify an expression of the fine-structure constant before h was discovered?

The Fine-Structure Constant

At any time from 1817 onwards, when Thomas Young had made observational estimates of both magnitudes, it was possible for a physicist to meditate on the ratio of the wave-lengths of the radiation from material systems to the diameters of the 'molecules' of which they were composed. For example, Cauchy suggested that the order of magnitude of the sizes of 'molecules' might be inferred from dispersion properties, but this proved wrong. After 1880, when the conception of electrical particles was being established and the empirical data were more reliable, increasing attention was paid to this ratio[5]. But Larmor was probably the first to consider it in the light of dimensional arguments applied to the theory of electrons moving in an electromagnetic continuum.

Larmor stated (p. 233) that "the very striking fact that the wave-lengths of free radiant vibrations of molecules [in which he includes atoms] are such large multiples of their diameters has always invited explanation. . . . On the dynamical conception here employed [radiation from rapidly moving electrons], it involves that the orbital velocities of the electrons are about of the same order of smallness, exceeding 10^{-3}, compared with the velocity of radiation, as are the molecular dimensions compared with the wave-lengths". Or:

$$V_e/c \doteqdot l_a/\lambda$$

which corresponds to the quantum mechanical relation:

$$A \, . \, V_e/c = \frac{B \, . \, h^2/4\pi^2 me^2}{C \, . \, h^3 c/8\pi^3 me^4} = \alpha$$

where A, B, C, are numerical factors which are functions of quantum numbers.

Thus Larmor correctly recognized the existence of a fundamental pure number, involved in electronic systems, which (with small numerical factors) must determine the ratios both of characteristic lengths and of characteristic velocities. The experimental facts led him to estimate this geometrical and kinematic ratio as of the order of 10^{-3}. Moreover, he gave the correct reason why V_e/c must be small, since "the energy of orbital groups moving with greater speeds would be through time sensibly dissipated through radiation, so that such groups could not be permanent". In fact, condensing Bohr's statement in 1932, the concept of stationary states only works because $\alpha \ll 1$, and the transition coefficients therefore small enough to be negligible in a first approximation.

Elsewhere (p. 346), Larmor argues that the internal energy function of the atom may be separated from the energy of the radiation, "for a disturbance in the aether can travel over about 10^3 diameters of the molecule during the period of a single vibration".

The radiative model on which Larmor based this analysis was that of systems of orbital negative electrons the net radiation of which was determined by the total resultant electric polarity of the atom. Though this model has been discarded, the dimensional relations underlying Larmor's argument remain valid. We call the above ratio the 'fine-structure constant' for reasons connected with relativistic dynamics, but from another point of view the associations of this name may be misleading. For Larmor's argument emphasizes that α may be regarded as a geometrical and kinematic ratio, a ratio of lengths and of velocities, into which mass enters only secondarily when it is necessary to compare radiative (electron and photon) processes with nuclear and other particle processes. Larmor's model gave the correct dimensional relations, but no model is yet known which can account for the empirical value of this ratio. While Larmor's principle asserts that a natural length is necessary in atomic theory, it does not explain why one is not sufficient.

My conclusion is that it was possible for Larmor to identify the fine-structure constant before h was discovered because this constant has geometrical and kinematic, as well as dynamical, consequences. This suggests the possibility that a geometrical and kinematic interpretation of the constant may one day help to throw light on its origin and value.

Ratio Electron/Proton Mass

In a discussion of the Zeeman effect (p. 341) Larmor first assumes, for simplicity, that e/m has the same constant value for all the electrical particles involved, and then shows that approximately the same result will be obtained if there are additional particles for which e/m is small in comparison with the value for all the others. "We may for example suppose the charges to be the same for all the ions, and the effective masses of the positive ones to be large compared with those of the negative ones . . . the velocities of the positive ones will be the smaller, inversely as the ratio of their masses."

During the 1890's values for e/m were becoming available from various sources, first indirectly and in 1897 from direct measurements ; e had been estimated from 1870 onwards ; and the masses of atoms had been determined from 1875 onwards. Thus it was natural during the 1890's to infer that positive charges were associated with much larger masses than that of the negative electron. But it seems that Larmor was one of the first to develop dimensional arguments employing the ratio electron/proton mass. Indeed, he formulated the conditions under which the motions of heavier particles can be neglected relatively to those of electrons ; for example, in calculations of the Zeeman effect, in which the influence of the magnetic field is treated as equivalent to a uniform ('Larmor') rotation of the system.

The Ratio Gravitational/Electric Actions

Larmor was interested in the weakness of gravitational relative to electrical actions and in the bearing of this on the problem of a unified theory of the two realms. In this connexion he posed the question, "Are the linear equations of the Aether exact ?" (p. 186). Clerk Maxwell's equations are linear, indeed "they must be so if all kinds of radiations are to travel with the same speed in the celestial spaces". But Larmor noted that the theory of the propagation of sound involves the neglect of terms (normally unobservable) of the order of the square of the ratio molecular velocities/velocity of sound. He therefore asked : "Why then should not relatively minute phenomena like gravitation be involved in similar non-linear terms, or terms involving differentials of higher orders . . . which are as insignificant compared with the main ( ) linear terms as is the gravitation between two electric systems compared with their ( ) electric forces ?"

He considers the difficulties in this assumption, and suggests that the smallness of the optical dispersion that would arise from such non-homogeneity of the aether "may be estimated by comparing the electric force between two ions with their gravitational attraction". Larmor's conclusion, on the basis of the facts available to him, was that "there is little to be urged in favour of leaving this loophole for the explanation of gravitation". This in conformity with doubts that he and others (for example, A. N. Whitehead) felt as to whether a heterogeneous continuum, without severe restrictive conditions, can provide a sufficiently stable basis for a theory of systematic measurements, that is, for the observed quantitative consistency between phenomena separated in space and time.

However that may be, we are to-day no more certain than Larmor was whether or not electrical actions correspond to the main terms and gravitational to residual ones in a non-linear field.

Chiral Properties

In a section "On Dynamical and Material Symmetry" (p. 140) Larmor considers the invariance properties of electrical systems under two transformations : time reversal, or the substitution of $-t$ for $+t$, and mirror reflexion, or the substitution of $-x$ for $+x$; invariance under changes of linear scale is treated elsewhere (pp. 176, 189). He is particularly interested in chiral[6] properties, and discusses these in several contexts (pp. 27, 142, 208).

Larmor enters into a detailed analysis of the influence of motion relatively to the aether on chiral properties, and discusses the connexions between chirality, reflexion, sign of electric charge, magnetic fields, and optical rotation properties. Part of his argument was challenged at the time, and it is now largely superseded.

Yet even here Larmor's insight is remarkable. One example (p. 27) will suffice : "The duality arising from the assumption of two kinds of electrons, only differing chirally so that one is the reflexion of the other in a plane mirror, will present nothing strange to those physicists who regard with equanimity even the hypothesis of the possible existence of both positive and negative matter". This was written in 1898.

Atomic Indeterminacy

Larmor divided physics into two related realms : (i) the fundamental 'molecular' phenomena (now called 'atomic') largely obscure to him, where discreteness plays a basic role ; and (ii) the 'mechanical' phenomena of the macroscopic smoothed-out averages of electromagnetic actions in the aether. He believed (at least until 1898) that the true connexion of the two realms would be discovered by interpreting fundamental electrical particles as knots, foci, or small regions of strain in the aether. Though this model for particles may seem naïve to-day, his clarity regarding the logical and mathematical inter-relations of micro- and macro-phenomena is impressive. Throughout the book his main concern is the nature of the relation of discrete actual distributions (mainly electric particles) to continuous macroscopic and directly observable actions (mainly the effects of currents and fields).

An eloquent passage (p. 272) describes the advance of physics from the macro- to the micro-realm "by the gradual reclamation of an empirical fringe surrounding the settled domain of the science". One cannot help thinking of Bohr's Correspondence Principle as one reads : "Here progress has been effected mainly by transferring to the molecule, considered as itself a material system [that is, for Lamor, atomic], dynamical ideas the same as or analogous to those that hold good in the mechanics of sensibly continuous bodies". He was aware of the contemporary ignorance regarding the atomic realm, and believed that the progress that was being made was only possible because the individual molecule is "a nucleus in that universal aethereal *plenum* that is the transmitter of half our impressions" and therefore must in some degree conform to laws based directly on macroscopic observation.

Yet "there can be an unlimited amount of molecular structure and function in a given system, which is unconnected with any mechanical effect occurring in that system treated as continuous matter" (p. 287). "Mechanical determinateness thus need not involve molecular determinateness".

Conclusion

By the time "Aether and Matter" was in print, Larmor had overcome the tendency to demand mechanical models of the aether (medium with rotational elasticity, vortex rings, wheels with bands, etc.) which had been prevalent between 1860 and 1890. Whittaker[7] considered that it was "chiefly under the influence of Larmor [that] it came generally to be recognized that the aether is an immaterial medium *sui generis*, not composed of identifiable elements having definite locations in absolute space".

Larmor's contributions to electro-magnetic and electron theory are fully reported in Whittaker's "History". Here I have been concerned with a different task: to show that Larmor saw far beyond the typical problems of 1900 to issues that are still unresolved. This was possible, I believe, because a radical theoretical analysis, applied with judgment, can sometimes lead beyond contemporary theories and help to open up new problems the solution of which may lie well ahead.

Certainly the main theme of Larmor's book, the relation of basic discreteness to macroscopic continuity, is far from exhausted to-day. There is no golden rule for discovering the new ideas which will prove fertile in relation to this problem, for example, in nuclear processes. But there is a rational method of preparing the ground: to analyse the known facts, and the hitherto successful theories, with as little prejudice as possible in terms of basic principles which appear worthy of confidence. It would be of great value to-day to be able to identify issues lying as far ahead as those Larmor recognized in 1900.

OBITUARIES

Dr. Andrew McKellar

ASTROPHYSICISTS have learned with great regret of the death, at the early age of fifty, of a well-known and very popular colleague, Dr. Andrew McKellar, assistant director of the Dominion Astrophysical Observatory, Victoria, B.C. McKellar was first brought into contact with astronomy as a summer student at the Dominion Astrophysical Observatory about thirty years ago, when he was an undergraduate at the University of British Columbia, Vancouver. He proceeded from there to the University of California, Berkeley, where he gained his Ph.D. and laid the foundations of the spectroscopic technique which later served him so well. After two years in the spectroscopic laboratories of the Massachusetts Institute of Technology as a National Research Council Fellow, he returned to Victoria, to become a permanent member of the staff, and spent the rest of his life there.

McKellar was the first to identify molecules in the interstellar gas, a matter of great importance for problems of interstellar matter, especially in relation to the equilibrium between gas and dust. These questions are part of larger problems involving the formation of stars from interstellar matter, about which so much is said and so little understood. McKellar's identification of these molecules was far more than an achievement of the obvious; the molecules are unsaturated, their bands in the conditions of interstellar space are reduced to one or two lines only, and these are usually quite faint.

McKellar was also one of the leading authorities on molecular bands in stellar spectra. He did a great deal of exploratory work in the red and near infra-red, discovering and identifying hitherto unrecognized bands. His most noteworthy achievement in this field, however, was to show that the ratio of abundance of the carbon isotopes carbon-12 and -13, while about 90 in some stars (as on Earth) is about 3½ in certain *R* stars, a significant fact for nuclear physicists and all who are interested in the origin of the elements. While working in the red region he also found that some carbon stars contain considerable quantities of lithium, an element which is normally present in stars only in very small quantities, presumably because it is easily destroyed by nuclear processes in stellar interiors.

Among other work, McKellar made important contributions in the rather difficult field of spectroscopy of comets. He was one of the first to aluminize a large telescope mirror. He took a leading part in the design of spectroscopic equipment at the Dominion Astrophysical Observatory. He was also a leader of the small group concerned with unusual eclipsing binaries such as ζ Aurigae, 31 Cygni, VV Cephei, where a comparatively small hot star is eclipsed by a large and cool supergiant. Absorption lines due to the atmosphere of the cool star appear near the beginning and end of eclipse and can be used to study the outer structure of the supergiant. Apart from the Sun, this is our only fairly direct means of exploring a stellar atmosphere. The results suggest an irregular field of huge and variable prominences, quite unlike the stratified layers of conventional theory.

Perhaps the most important feature of McKellar's work was his ability to obtain significant results without burdening astronomical literature with over-lengthy papers and irrelevant detail. He himself with characteristic modesty attributed this to economy of effort imposed by a very long illness, which he knew must eventually prove fatal. His many friends will miss "Andy's" quiet humour and charm, and will mourn an astronomer who had the gift of courage as well as of scientific insight. He leaves a widow and a son and daughter.

R. O. REDMAN

Mr. J. P. Mills, C.S.I., C.I.E.

James Philip Mills, who died at his home in Sydling St. Nicholas, Dorchester, on May 12, was born in 1890. He was the son of James Edward Mills, was educated at Winchester and Corpus Christi College, Oxford, and entered the Indian Civil Service in 1913. He was allotted to Assam, and in 1916 was posted to the Naga Hills, where he occupied himself at once on an ornithological survey of the district for the Bombay Natural History Society, but was soon caught up in the ethnographical work which constituted his major contribution to science. His monograph on "The Lhota Nagas" was published in 1922, and "The Ao Nagas" followed in 1927. After an absence on leave and a term as deputy commissioner of Cachar (whence he once wrote to me apropos of some controversy with a difficult planter, that he was contemplating a monograph on "Scotsmen and Other Hill Tribes of Cachar"), he returned to the Naga Hills as deputy commissioner, and "The Rengma Nagas" followed ultimately in 1937. Meanwhile, he had been appointed honorary director of ethnography for Assam (1930), and in 1943 he was appointed Advisor to the Governor of Assam for Tribal Areas and States, a post which enabled him to gain a very considerable knowledge of the hill tribes on both frontiers of the province as well as to make practical use of his anthropological knowledge and experience. Before this period he had been lent to the Bengal Government to recommend on the administration of the Chittagong Hill Tracts, and after touring there for two months, during which he covered some five hundred miles mostly on foot, he submitted a most discerning analysis of what was wrong with the existing condition of affairs and what was needed to improve the administration there.

Mills was made C.I.E. in 1941 and C.S.I. in 1947, in which year he retired. In 1948 he was appointed reader in the School of Oriental and African Studies, from which he retired in 1955. The bibliography of the ethnology of Assam which he compiled during this period has never been separately published though used by other bibliographers. In 1942 he was awarded the Rivers Memorial Medal of the Royal Anthropological Institute for his ethnographical work in the Naga Hills, and during 1951–53 he was the president of that society.

Mills made an admirable colleague in administration. Though not of very robust constitution he never spared himself, and was always ready to go anywhere and tackle anything; and his unfailing fund of humour and tolerant good temper endeared him to all who came into contact with him, even the wrongdoers who suffered at his hands. In Assam it is perhaps his many friends in the Ao Naga tribe who will most regret the news of his death.

He married in 1930 Pamela Moira, daughter of J. Foster Vesey-FitzGerald, who with two daughters survives him.

J. H. Hutton

NEWS and VIEWS

Mechanical Engineering at Manchester : Prof. H. Wright Baker

Prof. H. Wright Baker, head of the Mechanical Engineering Department at the Manchester College of Science and Technology, will retire this summer. Prof. Wright Baker was educated at Liverpool College and in the Engineering Department of the Faculty of Science, University of Manchester. After obtaining his first degree, he joined the War Victims Relief Committee and for four years was head of its transport department. He afterwards went back to his University Department as an assistant lecturer, being later promoted to lecturer and senior lecturer under the late Prof. A. H. Gibson. For his extensive researches into piston temperatures in internal combustion engines, he was awarded the D.Sc. degree. Prof. Baker was appointed to his present chair in 1939. During the War, the size of his Department grew steadily to cater for the training of Service personnel as well as of undergraduates. His Department continued to grow after the War to its present large size in accordance with national requirements; and its range of research and teaching activities broadened. During the past decade his interests have been directed towards developing workshop technology as a subject worthy of academic attention. Metrology was singled out as his particular interest, and under his ægis the Royce Laboratory was created and stands as one of the finest of its kind in Britain. Prof. Baker's interest in machine tools has led to special emphasis being placed on teaching and research in production engineering. He is a founder member of the International College of Production Engineering Research. Prof. Baker's publications consist of papers and books on thermodynamics, metrology and education. He has successfully pioneered a 'clearing house' system for students seeking university places in engineering, and his opening of the Bronze Dead Sea Scrolls—a matter of courage and considerable technical skill—is one for which he will long be remembered.

Prof. W. Johnson

Mr. William Johnson has been appointed to the chair in mechanical engineering in the Faculty of Technology of the University of Manchester, as from August 1960. Mr. Johnson was educated at the Central Grammar School for Boys and later at the College of Technology (as it then was) in the Faculty of Technology of the University of Manchester. After graduating in mechanical engineering in 1943, and having become an undergraduate in that Department a year after Prof. H. Wright Baker became the head, Mr. Johnson joined the Army and was afterwards commissioned in the R.E.M.E. He served until late 1947 in various workshops at home and abroad, joining the Home Civil Service as an assistant principal in 1948. Also in 1948 he took an external degree of the University of London in mathematics. In 1950, Mr. Johnson became lecturer in engineering at what was then the Northampton Polytechnic, London, and in 1952 he moved to the University of Sheffield, where he became interested in the theory of plasticity, especially as applied to the forming processes. The results of his researches appeared in a number of reports to the British Iron and Steel Research Association. Mr. Johnson was secretary of the Yorkshire Branch of the Institution of Mechanical Engineers between 1953 and 1956, in which year he was appointed senior lecturer in mechanical engineering in the Faculty of Science at the University of Manchester. His researches during this period in the Faculty of Science were extended, but especially he has made considerable contributions to knowledge about the fundamental mechanics of metal extrusion and forging. Mr. Johnson is editor and founder of the *International Journal of the Mechanical Sciences*.

Botany at Newcastle on Tyne: Prof. Meirion Thomas, F.R.S.

WHEN he retires from the chair of botany at King's College, Newcastle on Tyne, at the end of the present session, Prof. Meirion Thomas will have completed thirty-six years service in the Botanical Department of that institution, first as lecturer during 1924–43, then as reader until 1946 when he was appointed to the chair in succession to Prof. J. W. Heslop Harrison. After serving in the army throughout the First World War, first in the South Wales Borderers, but for most of the time with the Royal Engineers, Prof. Thomas entered Trinity Hall, Cambridge, where he remained until his appointment to the lecturership in Newcastle. At Cambridge, he combined the study of biochemistry and botany with achievement in the field of sport, obtaining his 'blue' in association football. Prof. Thomas is distinguished for his long series of researches in plant metabolism, particularly in regard to the respiratory and allied processes in apple fruit and succulent plants. Many of his papers have appeared in the *New Phytologist*. He was president of Section K (Botany) of the British Association at its Belfast Meeting in 1952 where his presidential address was a masterly review of our knowledge of such metabolic processes in higher plants. Prof. Thomas is also the author of a well-known text-book on plant physiology, the success of which may be judged from the fact that it is now in its fourth edition. His friends will wish him a long and happy retirement. He is to be succeeded by Prof. J. H. Burnett, professor of botany in the University of St. Andrews (see *Nature*, 176, 1002; 1955).

Bacteriology at St. Mary's Hospital: Prof. R. E. O. Williams

DR. R. E. O. WILLIAMS, who has been appointed to the chair of bacteriology at St. Mary's Hospital, has long maintained an interest in both the scientific and the clinical aspects of bacteriology. Dr. Williams was educated at Sherborne School and the University of London. He obtained a B.Sc. at University College in 1937 and read medicine at University College Hospital, qualifying in 1940. He entered the Emergency Medical Service in 1941 and transferred to the Medical Research Council Wound Infection Unit in 1942. In 1946 he joined the Public Health Laboratory Service and was appointed director of the Streptococcal and Staphylococcal Reference Laboratories and of the Air Hygiene Unit in 1949. Dr. Williams has made a special study of hospital cross-infection, and the laboratories in which he has worked and has later directed have made notable contributions to this field. His name is associated particularly with important research into air hygiene and the typing of streptococci and staphylococci. In the latter context the energetic development of phage typing in the epidemiology of staphylococcal infections has been of prime importance and owes a great deal to him and his group. Dr. Williams has published numerous papers on all the facets of bacteriology in which he is interested. He has travelled extensively and is well known to scientific colleagues in many countries.

Royal Society Tercentenary Exhibition

As one of the functions of the Royal Society tercentenary celebrations this year, a conversazione is to be held at Burlington House on the evening of July 23. There will be on this occasion an exhibition in the Diploma Galleries of the Royal Academy of Arts, illustrating British scientific achievements during recent years. The exhibition will differ somewhat from that usually arranged for a Royal Society soirée. There will be fifteen sections, each devoted to some field of science in which British contributions have been of outstanding importance, and in most cases several research centres will be represented in each section. The fields which have been selected are: calculating machines; physics of the Earth, ocean and atmosphere; exploration by radio; fundamental particles; solvent extraction of plutonium; refined chemical separation; metals; molecular structure of biological systems; abnormal hæmoglobins and human chromosomes; natural selection; microbial genetics; antibiotics; vitamins; electrophysiology; physiological and biochemical aspects of plant growth. The exhibition will remain open from 10.30 a.m. to 6 p.m. from Monday, July 25, until Friday, July 29. On Monday, Tuesday and Wednesday, admission will be by ticket only. Schools, colleges, scientific societies and professional institutions are being informed of the exhibition and tickets will be issued to them. On July 28 and 29 the exhibition will be open to the public.

U.S. Expenditure on Academic Research and Development

A PRELIMINARY report on research and development in colleges and universities in the fiscal year 1958 issued by the National Science Foundation shows that during 1954–58 expenditure on research and development in the natural and social sciences at colleges and universities in the United States increased from 409·7 million dollars to 735·8 million dollars, in which period Federal expenditure for research and development in colleges and universities proper increased from 140·7 million to 217·9 million dollars. In 1958 expenditure on research and development in colleges and universities proper amounted to 327·5 million dollars; agriculture experiment stations, including schools of agriculture, to 119·2 million dollars; and in Federal contract research centres, to 289·1 million dollars. At universities and colleges proper 74 per cent of this expenditure was on fundamental research, compared with 35 per cent at agricultural experiment stations and 24 per cent at Federal contract research centres. Of the total 735·8 million dollars, 186·4 million dollars was expended in engineering sciences (26·3 per cent on fundamental research); 262·3 million dollars on physical sciences (49·5 per cent); 251·5 million dollars on biological sciences (61·7 per cent); and 35·6 million dollars on social sciences (56·9 per cent). Of the 327·5 million dollars expended at colleges and universities proper, 67 per cent came from the Federal Government, 12 per cent from the Institution's own funds, 11 per cent from foundations, 8 per cent from industry and 2 per cent from other sources. Total indirect, or overhead, costs of conducting current research are estimated at 28 per cent of direct costs.

Pauli Memorial Room at CERN

At the suggestion of Mrs. Pauli, the personal library of her husband, the late Prof. Wolfgang Pauli, has been transferred to the European Organization for Nuclear Research (CERN) in Geneva. On June 14, following one of the meetings of the sixteenth session of CERN Council, a brief ceremony marked the inauguration of the Pauli Memorial Room, where the volumes composing the library of the great scientist have been housed. This consists of some 700 books dealing with literature and philosophy in addition to theoretical physics. It also includes sets of periodicals and a unique collection of reprints.

Mathematics, Education and Industry

The successful Oxford conference of 1957 on mathematical education and industry was followed up in 1959 by a similar conference at Liverpool, attended by teachers, research workers and industrialists (Mathematics, Education and Industry: a Record of a Conference of Teachers, Research Scientists, and Industrialists, held at the University of Liverpool, April 1959. Pp. 156. London: *Technology*, The Times Publishing Co., Ltd., 1960. 7*s*. 6*d*.). The summary of the papers and discussions now available ranges over a wide field; the teacher has now been told that while the research worker demands a high standard of mathematical technique, the needs of industry at the moment are for clear thought expressed through a fairly elementary technique. On the other hand, the teachers have been able to explain to the research workers and to the industrialists the limitations under which the school teacher of mathematics is obliged to work; in a school of moderate size, sixth-form mathematics cannot be split into a very large number of groups and a common core of work must be accepted, so that special interests cannot be sure of receiving full emphasis. One topic which should be further explored at a later conference is the place of numerical analysis in the school. On the present showing, the research workers and industrialists do not seem to be sure what they would like the schools to do, and the teachers do not seem to have studied available school texts which show what can be done. But on the whole this pamphlet leaves a very pleasing impression of increasing co-operation between the two parties.

National Museum of Canada

Since 1957 the annual reports of the National Museum of Canada have been discontinued, and an administrative report of the Museum appears in the annual report of the Department of Northern Affairs and National Resources. To provide for the publication of short papers, which formerly appeared in the annual reports of the Museum, a series of "Contributions" is now issued. These permit of the grouping of the papers into the various sciences covered by the Museum, and the first three deal with anthropology, botany and zoology (Canada: Department of Northern Affairs and National Resources. National Museum of Canada. Bulletin No. 160: "Contributions to Botany", 1958. Pp. iii+148 (3 plates). 2 dollars. Bulletin No. 162: "Contributions to Anthropology", 1957. Pp. iii+203 (28 plates). 2 dollars. Bulletin No. 166: "Contributions to Zoology", 1958. Pp. ii+59. 1 dollar. Ottawa: Queen's Printer, 1959 and 1960). The "Contributions" are well produced, amply illustrated and attain a high standard in scholarship. Typical papers deal with the salt-marsh vegetation of Churchill, Manitoba, some freshwater fishes from north-eastern Quebec and Labrador, the dentition of rabbits, and a description of Sadlermiut houses excavated on Southampton Island.

The Fauna Preservation Society

The annual report of the Fauna Preservation Society for the year ended December 31, 1959, records a deficiency of £153 on the year, but donations and legacies received during the year amounting to £4,435 have been credited to the General Reserve Fund and membership increased by 348 to 1,799 (pp. 12. London: Fauna Preservation Society, c/o The Zoological Society of London, 1960). This was due considerably to the interest aroused in the preservation of wild life by 'Operation Noah', launched to help the rescue work already begun by the Game Preservation and Hunting Association of Northern Rhodesia. The rescue ship *Erica* has been built and entered into service, and in June the Society undertook the work of the Survival Service Commission of the International Union for Conservation of Nature. A special investigation also was started into the position of the African black rhinoceros to consider whether this rhinoceros should be regarded as an endangered species and special efforts made for its preservation.

The Institute of Professional Civil Servants

The fifteenth annual report of the Institution of Professional Civil Servants, for the year 1959, presented to the annual delegate conference on May 23, characterizes the year as one of frustration, despite the 3·5 per cent pay supplement on salaries up to £2,000 a year, the Coleraine Committee's recommendations for the higher Civil Service, the 10 per cent increase in night-subsistence allowances and the commencement of the review of all subsistence allowances (pp. 64. London: Institution of Professional Civil Servants, 1960). Membership at December 31 was 51,632 compared with 52,239 in the previous year. The Institution continues to devote time and energy to publicizing the need for more scientific professional and technical workers, and for more, and better, planned use of this manpower; but the Pay Research Unit surveys and consideration of the reports on those surveys have involved an enormous time-lag, and this organization is to be reviewed in 1960. Concern is expressed at proposals for dealing with staff structure in the Atomic Energy Authority, and the report also describes negotiations dealing with the use and recruitment of professional engineers and particularly with the possible redundancy among such officers caused by devolution.

Isotope Information Bureau

The Isotope Information Bureau, situated on the ground floor of the London Office of the United Kingdom Atomic Energy Authority in Charles II Street, was opened on June 16 by Sir Roger Makins, chairman of the Authority. The ceremony was attended by Sir Hugh Beaver and Sir Ralph Cochran, representing the Federation of British Industries, and by representatives of the Institute of Directors, the British Institute of Management, the Department of Scientific and Industrial Research and the Board of Trade. Sir Roger, in an address of welcome, said that the Authority felt that the stage had now been reached at which radioisotopes could be regarded as true and tried tools and that industry would gain great benefit from their widespread adoption. He expressed the hope that all those interested in the production and use of isotopes would take the opportunity of visiting the Bureau, where the Authority was putting radioisotopes in the 'shop window'. Sir Hugh Beaver, acting president of the Federation of British Industries, commended the Authority on the excellent work it had done on research and development into isotope uses, and expressed the hope that industry would come forward and make use of the facilities which the Authority could make available in the form of advice and consultancy. The Bureau, which is open to the general public, is to be staffed by scientific personnel from the Authority's Radiochemical Centre at Amersham, who will be able to give on-the-spot advice to industrialists, doctors and research workers. Radioisotopes, the trade in which already amounts to nearly a million pounds, are widely used in industry, medicine, agriculture and research in the United Kingdom, and the Authority's Radiochemical Centre at Amersham supplies isotopes to more than sixty countries in all five continents. Sir Roger remarked that the use of radioisotopes by British industry could easily be increased tenfold.

International Co-operation and the Production of Calcium-47

FOLLOWING a meeting of experts on the production of calcium-47 convened by the International Atomic Energy Agency in Vienna in December 1958, there have been successful efforts to produce this very useful radioisotope in Great Britain and the United States. Agency research contracts have so far been awarded to institutions in France and Sweden to promote research on production as well as practical applications of Ca-47. As reported at a second meeting held in December 1959 in Vienna, limited amounts of this isotope are now available from Amersham and Oak Ridge. Although the present Ca-45 contamination would not permit the use of this product for experiments on normal healthy persons, it is considered satisfactory for diagnostic and research work in patients and for agricultural and other applications. The International Atomic Energy Agency is now developing a programme to assist, through research contracts, users of this isotope to procure it and to co-ordinate further work on applications of Ca-47 as well as its production by methods other than the calcium-46 $(n\gamma)$ – calcium-47 reaction.

Addiction-producing Drugs

IN its tenth report, the Committee on Addiction-producing Drugs which was set up by the World Health Organization recommends that eight new substances derived from different chemical groups and all having morphine-like effects should be subject to international control (Technical Report Series, No. 188. Pp. 16. Geneva: World Health Organization; London: H.M. Stationery Office, 1960. 1 Swiss franc; 1*s*. 9*d*.; 0.30 dollar). These substances are allylprodine, benzethidine, furethidine, lævophenacylmorphan, metazodine, norlævorphanol, phenazocine and piminodine. The Committee feels that the fundamental criterion for the establishment and degree of control is the extent to which drug-induced behavioural disturbances are a risk to the community, for neither the chemical structure *per se* nor any definition, however descriptive, can be a complete guide indicating which substances should be placed under control. Consequently, there is a need for research along various lines in the field of drug-addiction. In particular, to help the World Health Organization in carrying out its functions, the Committee must have at its disposal the results of basic and applied research in this field. So far, insufficient support has been forthcoming for such investigations. The Committee strongly urges that research on drug addiction should be strengthened and expanded, since it continues to be a serious international health problem. The Committee makes certain technical comments concerning the draft of the Single Convention on Narcotic Drugs. It expresses the view, *inter alia*, that only those preparations should be retained as exempted preparations which constitute no risk to public health, and from which the potentially addicting agent is not readily recoverable.

Mud Fauna of the Stour Estuary

ONE of the most striking features of any estuary is the replacement of freshwater animals by marine animals as the river progresses towards the sea. In spite of the presence of numerous estuaries in the British Isles, surprisingly few accounts of their ecology have been published. A study of the River Stour estuary was made by Frances Bull, Helen Honeyman and Susan Knott over a period of three weeks during June 1958 (Transactions of the Suffolk Naturalists' Society, including the Proceedings of the year 1959. Vol. XI, Part III. Pp. 217–288. Ipswich: Miss Janet C. N. Willis, Honorary Secretary, 1 Holly Road, 1960. 7*s*. 6*d*.). The scope of the investigation was limited to burrowing animals and to their distribution in relation to salinity, substrate, and their level on the shore. Although no hard and fast lines can be drawn, the fauna of the estuary roughly falls into three groups, depending on where each species attains a maximum density. It can be inferred that a maximum density implies optimal conditions for the life of the species. There are those species which have their maximum density in the upper reaches of the estuary, although they may occur in limited numbers right down to Shotley. Examples of this group are *Corophium volutator*, *Nereis diversicolor* and *Streblospio shrubsolii*. At the other end of the scale are those species which do not penetrate to the top of the estuary and have a maximum density towards the seaward end. These, for example *Cardium edule* and *Nephthys hombergii*, are generally marine species which have managed to penetrate the estuary. Although they can live in waters of lower salinity than the sea, they appear to be unable to survive the wide fluctuations of the upper reaches. Finally, there are those species with a mid-estuarine maximum, for example *Hetercirrus* sp., *Scoloplos armiger* and *priapulos caudatus*. A striking feature of the distribution of animals in the estuary is that, as soon as salinities become constant between high and low water, and the overall salinity higher, the total number of animal species rises, although the maximum density of any one is usually lowered. At Buck's Horns a total of 866 *Corophium volutator* and 720 *Nereis diversicolor* were collected from four stations, while an odd *Scrobucularia plana* and *Cyathura carinata* were the only other species present. The other extreme is shown by the transect at Shotley, where eighteen different species were found; the maximum number of any one species collected was 137 *Scrobucularia plana* from six stations.

Scottish Geology

TWENTY-ONE years ago the Geological Survey of Great Britain inaugurated a new publication, the *Bulletin*, to accommodate short scientific reports by members of its staff, and since then more than seventy noteworthy papers on British geology have appeared within its covers. The latest number (*Geol. Surv. G. Britain Bull.*, No. 16. Pp. 178+11 pl. London: H.M. Stationery Office, 1960. 20*s*. net) is a compilation of seven contributions to the geology of Scotland. Two of them describe the strata encountered in deep borings sunk by the National Coal Board in the Firth of Forth, off the coast of Fife, to prove the geological structure beyond the present limits of undersea mining. A third presents a full discussion of the remarkable and little-understood post-diagenetic replacements of coal seams by limestone, found locally in the Coal Measures of Ayrshire and in some other British coalfields. Other papers are concerned with Carboniferous lamellibranchs, with the classification of Scottish Carboniferous strata, and with the igneous rocks of the Pentland Hills; and the volume concludes with a petrological account of the sea-stack of Rockall, based on specimens collected when it was 'annexed' by H.M.S. *Vidal* in 1955. This almost inaccessible islet of aegerine-granite, 200 miles west-north-west of the Outer Hebrides, is renowned as a geochemical curiosity, and it has given its name to the rare rock-type rockallite, present in the granite as veins and segregations which are outstandingly rich in cerium and zirconium.

Parametric Amplification

A RECENT issue of *Philips Technical Review* contains an article entitled "Experiments in the Field of Parametric Amplification", by B. Bollée and G. de Vries (21, No. 2 (1959–60), obtainable from N. V. Philips' Gloeilampenfabrieken, Eindhoven, Holland). The principle of parametic amplification is described on the basis of the century-old Melde's experiment (*Ann. Physik u. Chemie.*, 109, 193; 1860), in which a taut slightly elastic string is pulled lengthwise at the appropriate frequency—nowadays termed the 'pumping' frequency—causing the string to vibrate transversely at half this frequency. The electrical analogue is a resonant circuit in which the capacitance is varied periodically. One example of a voltage-dependent capacitance is the germanium diode, which has already been used by some workers as the basis of a parametric amplifier. The authors of the article, however, describe a system which uses a magnetostrictive resonator of 'Ferroxcube' as the basis of the variable capacitor. Longitudinal vibrations are produced in the core, which is centrally clamped; the ends of the core are ground to be parallel to each other, and opposite each of them is mounted a parallel, fixed electrode at a spacing of 80μ, giving a total capacitance of 532 *pF*. With a pumping frequency of 22 kc./s., satisfactory 'noise-free' oscillations were obtained at half this frequency, and various theoretical predictions were verified. Another system, briefly described in the article, uses a piezoelectric resonator with a pumping frequency of 3 Mc./s. This gave results similar to those obtained with the magnetostrictive pump.

Index of Crystallographic Supplies

PREPARED under the editorship of Dr. A. J. Rose (Université de Paris, Laboratoire de Minéralogie et Cristallographie), the "Index of Crystallographic Supplies" is the second in the series of indexes undertaken by the Commission on Crystallographic Apparatus of the International Union of Crystallography (Union Internationale de Cristallographie: Commission des Appareils Cristallographiques. Répertoire de Metériel Cristallographique. 2e Édition. Pp. xxvi+126. Paris: Société Francaise de Minéralogie et de Cristallographie, 1959. 1,250 francs; 2.50 dollars). The first, entitled "Index of Manufacturers of Apparatus and Materials used in Crystallography", was compiled by Prof. A. Guinier and published in September 1956. The information contained in the present Index has been taken from manufacturers' catalogues, and no attempt is made to assess the relative merits of the equipment listed. The volume consists of four parts. Part 1 lists equipment and suppliers, classifying the material in eleven groups according to their fields of application and giving brief specifications to help crystallographers in their selection; Part 2, consisting of three chapters, quotes references to publications concerned with the reading and interpreting of patterns, books and text-books, and the names of periodicals with either the word crystallography or mineralogy in their titles or sub-titles; Part 3 consists of classified advertisements; and Part 4 gives the addresses of manufacturers and suppliers. The table of contents is in English, French, German and Russian, and the rest of the text in a mixture of mainly English and French. The Index is being distributed gratis to all crystallographers, but additional copies can be purchased from the International Union.

Organization for European Economic Co-operation: American Awards

THE Organization for European Economic Co-operation and the National Science Foundation recently announced award of the first twenty-seven senior visiting fellowships in science. These awards are designed to improve scientific work at the Fellow's home institution by training the Fellows in specialties that the institution desires to strengthen. The National Science Foundation is administering the fellowship programme for United States citizens. The recipients will study primarily in member countries of the Organization for European Economic Co-operation, and several will visit more than one country. They will work in Australia, Austria, Denmark, France, the Federal Republic of Germany, Italy, The Netherlands, Portugal, Sweden, Switzerland and the United Kingdom. Scientists from the member countries will also study in the United States under this programme, which is supported by the Organization and the United States.

The Biological Engineering Society

A NEW Society, called the Biological Engineering Society, was inaugurated at a meeting held at the Royal College of Surgeons on June 10. The meeting was attended by doctors, physiologists, electronic engineers, mechanical engineers and physicists from many parts of the country. The purpose of the Society is to bring together members of these different disciplines, from hospitals, research institutes and industry, to further the applications of engineering to biological and medical problems. Prof. R. Woolmer, professor of anæsthesia at the Royal College of Surgeons, was elected first president. The Council consists of: Dr. P. Bauwens, Prof. A. V. Hill, Dr. A. Nightingale, Dr. G. Pampiglione, Mr. W. J. Perkins, Mr. B. Shackel, Dr. N. Smyth, Dr. A. M. Uttley, Mr. H. S. Wolff, Dr. B. M. Wright. The acting secretary is Dr. A. Nightingale, Physics Laboratory, St. Thomas's Hospital, S.E.1.

Lady Tata Memorial Trust

THE Trustees of the Lady Tata Memorial Trust, on the recommendation of the (European) Scientific Advisory Committee, have made the following awards for research on leukæmia and allied diseases in the academic year beginning October 1: *Grants for research expenses*, Dr. B. M. Braganca (Indian Cancer Research Centre, Bombay); Dr. J. Pontén (Pathology Institute, Uppsala); Dr. M. Simonsen (Institute of Pathological Anatomy, Copenhagen); Dr. H. J. Woodliff (New Pathological Laboratory, Radcliffe Infirmary, Oxford). *Scholarships*, Dr. L. Chieco-Bianchi (Institute of Pathological Anatomy, Bari); Dr. J. Hastrup (Institute of General Pathology, Aarhus).

University News: London

THE following appointments have been announced: Dr. H. Harris, reader in biochemical genetics at the London Hospital Medical College, to the University chair of biochemistry tenable at King's College; Mr. A. F. Huxley, reader in experimental biophysics in the University of Cambridge, to the Jodrell chair of physiology tenable at University College.

Yale

THE following changes in staff of the Department of Botany in Yale University have been announced: Prof. Paul B. Sears (conservation and ecology) will retire as from July 1, 1960. Prof. Oswald Tippo (anatomy) will leave his post as chairman of the Department to assume duties as provost of the University of Colorado at Boulder as from July 1, 1960. Assistant Prof. Theodore Delevoryas (palæobotany) will leave to accept a post as associate professor in the Department of Botany in the University of Illinois. Assistant Prof. Kenton L. Chambers (cytotaxonomy) will leave to accept a post as associate professor and curator of the Herbarium in Oregon State College. Prof. Arthur W. Galston (plant physiology) has been appointed chairman of the Department as from July 1, 1960. During the academic year 1960–61, when Prof. Galston will be on sabbatical leave at the Commonwealth Scientific and Industrial Research Organization, Canberra, Australia, Prof. Norman H. Giles (cytogenetics) will serve as acting chairman. Dr. Ian M. Sussex (plant morphogenesis), of the Department of Biology, University of Pittsburgh, has been appointed associate professor. He will assume his post on July 1, 1960, and will teach courses in anatomy and developmental morphology. Dr. Diter H. von Wettstein, of the Forest Genetics Institute in Stockholm, has been appointed associate professor as from July 1, 1961. Dr. von Wettstein will set up an electron microscopy laboratory in the Department, and will give courses in electron microscopy and in sub-cellular morphology. Dr. William S. Hillman (plant physiology) has been appointed assistant professor. He will aid in the teaching of advanced plant physiology and in the supervision of graduate students. Dr. John H. Miller (developmental morphology) has been appointed instructor. His primary duties will be to take the elementary biology course. Dr. Derald G. Langham (genetics), formerly head of the Departments of Genetics in Caracas and Maracay, Venezuela, has been appointed lecturer. He will give a course in economic botany.

Announcements

THE following were elected officers of the Royal Statistical Society on June 15: *President*, Prof. M. G. Kendall; *Honorary Secretaries*, Mr. B. Benjamin, Dr. P. Armitage and Mr. B. P. Emmett; *Honorary Treasurer*, Mr. C. T. Saunders.

THE Royal Aeronautical Society Man Powered Aircraft Group has announced that it will make financial contributions to one or more persons or organizations who submit promising projects designed to further the achievement of man-powered flight. Submissions must reach the Royal Aeronautical Society not later than October 31. Further information can be obtained from the Chairman of the Man Powered Aircraft Group Committee, Royal Aeronautical Society, 4 Hamilton Place, London, W.1.

THE Committee on the Problem of Noise, of which Mr. A. H. Wilson is chairman, which was appointed by the Minister for Science "to examine the nature, sources and effects of the problem of noise and to advise what further measures can be taken to mitigate it", is now ready to receive evidence from persons and organizations with special interest or experience in matters relevant to the problem of noise. Anyone wishing to give evidence should first write to the secretary of the Committee, Mr. R. S. Matthews, Ministry of Health, Savile Row, London, W.1.

IN an admirable Library Association Pamphlet (No. 20: The Reproduction of Catalogue Cards. By Philip S. Pargeter. Pp. 48. London: Library Association, 1960. 8*s*. 8*d*.; L.A. Members, 6*s*. 6*d*.), Mr. P. S. Pargeter provides a comprehensive illustrated survey of the various means used for this purpose, including wax-stencil duplicators, spirit duplicators, offset lithography, metal plate, stencil and spirit addressing machines, microphotography, xerography, reflex copying, dyeline processing and automatic typewriter. The advantages and disadvantages of each method are recognized and there is a list of the principal periodical articles consulted.

A COURSE in practical field techniques in physical and cultural geography is to be held in south Devon during August 17–31 under the auspices of the Geographical Association. Further information can be obtained from the Assistant Secretary of the Association, Park Branch Library, Duke Street, Sheffield 2.

AN international congress on "Biophysics" will be held in Stockholm during July 31–August 4, 1961. The meeting will be divided between a series of symposia devoted to special topics in biophysics and to presentations of a number of contributed papers in pure and applied biophysics submitted by the participants. Further information can be obtained from Dr. Bo Lindström at the Department of Medical Physics, Karolinska Institutet, Stockholm 60, Sweden.

THE fifth general assembly of the International Union of Crystallography will be held in Cambridge during August 15–20 at the joint invitation of the University of Cambridge and the Royal Society. These meetings will be followed by symposia during August 22–24, namely, "Thermal Motion in Crystals and Molecules", and "Lattice Defects and the Mechanical Properties of Solids". Further information can be obtained from Dr. W. H. Taylor, Crystallographic Laboratory, Cavendish Laboratory, Cambridge.

NEW BIOLOGY BUILDING OF THE UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH

A NEW Biology Building to accommodate the Departments of Botany and Zoology of the University College of Wales was officially opened by Sir Keith Murray, chairman of the University Grants Committee, at Aberystwyth on April 27.

The Departments of Botany and Zoology had been housed for many years in old-fashioned buildings too small for their needs, so that a move to new quarters was eminently desirable. The new building which now contains these Departments is situated on a hill behind the town, with an excellent view over Cardigan Bay, on the new College site, an area of former farmland which is large enough to take as many new buildings as the College is likely to need in the foreseeable future. The Biology Building is the third one to be erected on this site, the others being a men's hostel and the Institute of Rural Science. The College therefore now has a nucleus of a 'campus' about half a mile from the town. The architects for all these buildings were Sir Percy Thomas and Son, Cardiff.

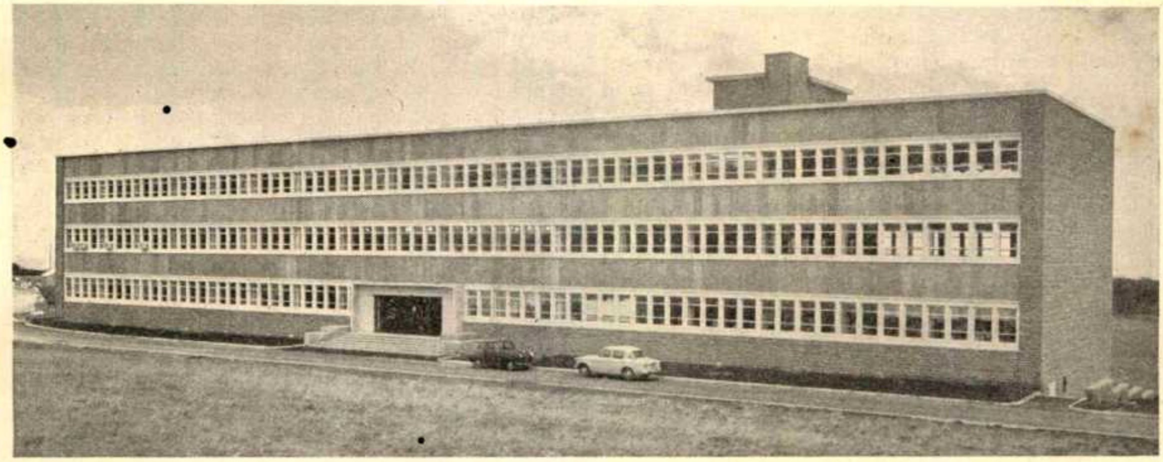

Fig. 1. The Biology Building at the University College of Wales, Aberystwyth

In general plan the building consists of four floors, with a large lecture theatre projecting towards the sea from the middle of the lowest floor. The Botany Department has the north end of each of the four floors, the Zoology Department the south end.

Rooms shared by the two Departments are situated in the centre of the building; this applies to the joint library and staff common room on the first floor. The joint lecture theatre seats 190 and is provided with a projection room and modern equipment for showing sound films and colour transparencies. The present number of students in each of the Departments is about 150.

The planning and design of the new Botany Department was carried out by Prof. Lily Newton, in consultation with the architects and staff. Special attention was given to the provision of adequate teaching laboratories for the second- and third-year classes, and the two large laboratories provided for these classes are excellently equipped for general botanical work. There are also special laboratories for the honours students and for advanced classes in plant physiology. Preparation rooms have been provided on each floor, to serve these laboratories. The botany lecture room accommodates 100 students, and there is a seminar room which is also used as a herbarium.

Specially equipped rooms for teaching and research in mycology, and a general research laboratory, are located on the second floor. The ground floor is allocated to plant physiology and biochemistry, and includes the laboratory for advanced classes in this subject, and several research laboratories. There are special facilities for enzymology, the use of radioactive materials and work on plant hormones. Four large growth rooms, with controlled lighting, temperature and humidity, provide facilities for controlled environment studies. All the physiological laboratories are served with water, gas, electricity and vacuum lines. The accommodation in the basement includes photographic dark rooms, workshop and a laboratory specially equipped for algological work.

In the old building, many lines of research were severely handicapped through shortage of space, poor services and inadequate equipment. The greatly extended accommodation and facilities, and the provision of a considerable amount of modern scientific equipment in the new Department, now meet the requirements for present-day botanical research.

The Zoology Department has been planned on the principle that in a small, rather remote situation it is better to make reasonable provision for several aspects of a subject than to make comprehensive provision for any one particular line of teaching or research at the expense of the others. The Department is therefore equipped to teach comparative anatomy, physiology and embryology, together with genetics and ecology: and for students who reach the honours or postgraduate levels it also teaches entomology, parasitology and marine biology. If there is any special emphasis in the equipment provided, it is in the direction of ensuring that adequate arrangements exist for teaching and research in the field of comparative physiology, because the future of zoology is so much bound up with this that no department can expect to contribute substantially to the progress of the subject unless it is well equipped for such work.

The various rooms in the Department (about sixty) are so arranged that the circulation of large numbers of students is confined in the main to the two lower floors, with the result that senior students and staff have the two upper floors to themselves. Thus the large lecture theatre opens from the basement, and the main students' cloakrooms are on the same level. On the floor above is the large laboratory, with the zoology lecture room opening from the same passage. The floor next above this one is laid out primarily for senior physiological teaching and research, and also has a technicians' common room, a larger common room for the academic staff, and the library. The top floor provides private rooms for the staff and for postgraduate research, as well as the honours laboratory with an adjacent room for section-cutting.

Several other principles have been kept in mind during the planning. Plenty of store-rooms have been provided, and also an adequate number of photographic dark-rooms situated on different floors, so that technicians, research students and academic staff do not need to use the same ones. Further, the teaching laboratories have been supplied with large and well-equipped preparation rooms opening into them, and this much facilitates the handling of teaching material. In connexion with the physiological section of the Department there is an aquarium in which various types of work can be done, and this room has a circulation of sea water through six small tanks and a circulation of fresh water through six others. In the basement there is a museum, and an innovation on the same floor is a visitors' research laboratory in which are four cubicles, each of which can be used by a visiting scientist, as well as general facilities which visitors can share. There are also two constant-temperature rooms: and compressed air is laid on throughout the building. A laboratory properly equipped for the use of radioactive materials has been provided on the roof.

The whole planning of the internal detail of the Zoology Department was done, in consultation with the architects and the staff, by Prof. and Mrs. T. A. Stephenson.

Aberystwyth is in many ways very favourably situated for biological studies, since there are close at hand a wide variety of habitats, which include not only the sea and shore for marine studies, but also inland rivers and lakes, woodlands, bogs, moorland, sand-dunes and salt-marsh. Moreover, there is a large botany garden very close to the new building. In the past the Biological Departments were handicapped by inadequate laboratory accommodation; but with the large new laboratories and the close proximity of a wide variety of natural vegetation and fauna, the College can now offer opportunities for biological teaching and research which compare favourably with those provided elsewhere in the United Kingdom.

T. A. Stephenson
P. F. Wareing

BOUNDARY-LAYER RESEARCH IN FLUIDS

When a body of streamlined shape moves through a fluid, the latter is disturbed, but in the main it is not carried along with the body. On the surface of the body, however, the fluid shares the body's motion, because viscosity prevents any slip occurring. The change in speed between the fluid at the surface adhering to it and the fluid in the external flow takes place in a thin layer, called the boundary layer. Boundary-layer flow has been intensively studied because many important practical effects depend on the nature of this flow. The fluid exerts a frictional retarding force on the body. This drag depends on the way in which the fluid speed varies across the boundary layer, and it tends to decrease as the boundary-layer thickness increases. It is increased if the flow in the boundary layer, instead of being completely smooth or laminar, is turbulent, with a small-scale eddying motion superimposed on the mean motion. Much work has therefore been devoted to the conditions which provoke the transition from laminar to turbulent flow in the boundary layer.

Another important practical problem is boundary-layer separation. Relative to the body, the boundary-layer fluid has less momentum than that in the external flow. Hence if over the surface of the body the pressure rises in the stream direction, the boundary-layer fluid may be brought to rest, because it will tend to be retarded relatively more by the pressure gradients than the fluid in the external flow. A piling-up of low-speed fluid near the surface may therefore occur, which may make the streamlines in the external flow depart markedly from the shape of the body. A low-pressure region over the rear end of the body sometimes results, with a consequent large pressure-drag. Here again turbulent boundary layers behave very differently from laminar ones, being much less prone to separation. In recent years, with the advent of high-speed aircraft and missiles, aerodynamic heating has become of great importance. This is largely a boundary-layer effect, because it is mainly due to the kinetic energy of the free-stream air being converted into heat when, relative to the body, the air is slowed down by friction inside the boundary layer. Associated with their greater frictional drag, turbulent boundary layers tend to produce greater rates of heating than laminar ones.

It can be understood from the foregoing that the study of boundary layers as a special department of fluid mechanics has itself become specialized into several sub-departments. These specialist interests are exemplified by the papers presented at the meeting on "Boundary Layer Research" arranged by Dr. W. P. Jones of the Aerodynamics Division, National Physical Laboratory, on behalf of the N.A.T.O. Advisory Group for Aeronautical Research and Development and held in London during April 25–29. The topics discussed were grouped under the following headings: (1) effects of roughness on boundary-layer stability; (2) boundary-layer control; (3) stability of shear layers; (4) mechanism of transition and boundary-layer stability; (5) three-dimensional boundary layers; (6) turbulent boundary layers; (7) heat transfer.

About forty papers were read by authors from Belgium, France, Germany, Great Britain, Italy, and the United States, and it is obviously out of place to attempt to summarize them all here. It may, however, be profitable to discuss the topics of some of the above headings in broad terms, in the light of the papers presented at the meeting.

The position at which transition to turbulent flow occurs on a smooth surface depends on several factors. If the surface is a flat plate parallel to the flow, it might at first sight be expected that the only factors affecting the distance x_t of the transition position from the leading edge of the plate would be the density ρ, the viscosity μ, and the velocity V of the oncoming flow. Then $\rho V x_t/\mu$, which is a dimensionless quantity of the kind known as a Reynolds number, would take a definite value at transition. However, in practice the Reynolds number of transition is not uniquely defined. It is very dependent on the magnitude of any small disturbances present in the stream or on the nature of any imperfections in the surface. Small wave-like disturbances introduced into the laminar boundary layer by these means can become amplified and distorted until eventually the flow becomes turbulent. These processes have been for many years and still are the subjects of theoretical and experimental investigations, and many papers at the meeting were concerned with them. The initial small wave-like motions can be treated with some success mathematically because the problem can be linearized. The disturbance velocities are superimposed on those of the undisturbed flow, and any products of the disturbance terms in the equations are neglected, the first-order terms only being retained. A further simplification usually introduced is to consider only two-dimensional disturbances, such that the disturbance velocities do not vary along lines perpendicular to the flow across the flat plate on which the boundary layer is formed. The justification for this is that it can be shown that such two-dimensional disturbances are more rapidly amplified than three-dimensional ones. However, three-dimensional disturbances that are not too oblique can be amplified, and this process has recently been studied because experiment has emphasized that the final process of breakdown into turbulent flow is essentially three-dimensional, with disturbance velocities in all directions superimposed on the mean flow. However, the disturbances considered by linear theory, even in its three-dimensional form, are different in character from those which immediately precede the breakdown into turbulent flow, and to help to bridge this gap in our theoretical understanding, other workers have taken into account some of the higher-order non-linear terms in the equations. Another difficult problem has been the extension of the linear small-disturbance theory to high-speed flow. It has recently been discovered that the earlier version of this extension is in some respects unsound, and a more adequate theory is now being developed.

Surfaces such as aircraft wings are never perfectly smooth, and it is therefore important to investigate what effects randomly distributed elements of roughness are likely to have on transition to turbulent flow. This problem is too complicated to study theoretically, and its experimental investigation is not easy, because it is complicated by the large number of factors defining the roughness—the spacing, height, and shape of the excrescences may all vary. For a band of roughness elements of given geometry situated transversely to the flow, transition will be provoked immediately downstream of the band if the roughness size exceeds a certain minimum. This critical size can be defined by a Reynolds number based on the height of the excrescences and on the velocity, density, and viscosity in the oncoming boundary layer at a distance from the wall equal to the height of the excrescences. There is some evidence that such a critical Reynolds number tends to be constant irrespective of the free-stream Mach number (the ratio of the speed to the local speed of sound), and also irrespective of heat transfer between the stream and the surface. If this is so, cooling a surface with distributed roughness would tend to provoke earlier transition, since it would increase the roughness-element Reynolds numbers. This is in contrast with the behaviour of boundary layers on smooth surfaces, where cooling delays transition.

Results of wind-tunnel investigations of transition may not be in all respects valid for free-flight conditions. Turbulence in the free stream outside the boundary layers may be much higher in a wind tunnel than in flight, where small-scale turbulence is usually negligible. In low-speed wind tunnels this free-stream turbulence may be reduced to a low level by the provision of a large settling chamber containing gauze screens through which the air is made to pass upstream of the working section, where the model under test is situated. However, in high-speed wind tunnels the free-stream turbulence cannot be so readily got rid of, since in the main it comes from acoustic radiation from the eddying motions in the turbulent boundary layers on the tunnel walls. A tentative partial explanation of why this radiation is greater at supersonic than at subsonic speeds is as follows. Eddies in the boundary layer move along with the local speed, so that the external flow moves past them. In effect, from the point of view of the external flow an eddy may form a moving local excrescence or depression. When the speed of the relative motion between the external flow and the eddy is less than that of sound, the disturbance generated in the external flow would be expected to be diffuse, tending perhaps to cancel with contributions from other eddies. On the other hand, when the speed of the relative motion exceeds that of sound, the effects of the disturbances are presumably concentrated along shock waves, and they might tend to persist without cancellation in the external flow. If this explanation is correct, it implies that the bulk of the radiated energy comes from the eddies in the inner part of the boundary layer, moving at supersonic speeds relative to the external flow, and not from eddies in the outer part of the boundary layer, where the relative motion is subsonic. In any event, the radiated energy is associated somehow with the turbulent motions in the boundary layer. If the tunnel could be run at sufficiently low pressures it would be possible to have laminar boundary layers on the tunnel walls, which would greatly reduce the free-stream turbulence-level. Under these conditions, however, the tunnel could not readily be used to study transition, because the boundary layers on any model in the tunnel would normally be entirely laminar.

It is still a matter for conjecture as to how similar turbulent boundary layers in supersonic flow are to those in low-speed flow. At high speeds, but not at low speeds, significant temperature and density fluctuations occur, and at first sight it would appear that they must completely alter the nature of the flow. However, it can be argued that the velocity fluctuations are to some extent independent of the thermal effects, and many of the overall characteristics of supersonic turbulent boundary layers are sufficiently similar to the corresponding ones in low-speed flow to encourage the view that there is a fundamental similarity in the underlying processes of energy exchange between the mean motion and the turbulent eddies, at least up to moderate supersonic speeds. The energy radiated to the free stream, discussed above, may not play a very big part in the overall energy balance.

A disturbing feature that has been noticed in tests of supposedly two-dimensional turbulent boundary layers is the presence of three-dimensional effects. Such characteristics as the boundary-layer thickness have been found to be non-uniform for the boundary layer on a flat plate along lines across the plate perpendicular to the flow. These effects are not to be traced to any small imperfections in the leading edge of the plate, but they seem to depend on the condition fo the screens in the settling chamber of the tunnel. It has been shown that characteristics such as the frictional drag, as calculated from the rate of growth of the boundary layer, are considerably affected by taking into account the spanwise variations.

Spanwise variations of a somewhat similar kind have been observed in regions where a laminar boundary layer re-attaches itself to a surface downstream of a region of separation. Liquid which, after being smeared on to the surface, evaporates most rapidly from regions where the skin friction is highest, reveals a streaky pattern with streaks parallel to the flow. This is suggestive of a number of parallel vortices in the boundary layer, with their axes in the direction of the stream. Such vortices are formed when a fluid flows over a concave surface, as has been known for a long time. The laminar boundary layer on such a surface is unstable because if a relatively fast-moving particle of fluid gets displaced nearer to the surface, where the general speed of the fluid is less, it comes into a region where its centrifugal force exceeds the restoring force exerted by the local pressure field, which is such as to balance the local, smaller, centrifugal forces. Thus the motion is unstable, and pairs of counter-rotating vortices result. It would seem at first sight reasonable to expect a similar instability in a re-attachment region, where the streamlines tend to be concave even when the solid surface is flat. However, it was found that the streaky pattern persisted even when the surface on which the re-attachment occurred was made convex. This would presumably damp out any instability of the concave-surface type, so the cause of the streaky patterns remains at present a mystery.

Many other topics were considered at the meeting, but there is no space to describe them here. It will already be evident, however, how abundantly fruitful has proved the concept of the boundary layer, first thought of by Prandtl more than fifty years ago, in 1904. In the decade following that year scientific papers on boundary layers appeared at the rate of about one a year. The current rate has been estimated to be about 160 a year, and this rate is still increasing. Despite all this effort, we are still a long way from understanding many boundary-layer phenomena. The attempt to solve these problems is one of the most interesting tasks of present-day aerodynamics, a task which is likely to take at least another fifty years to complete.

G. E. Gadd

THE BRITISH LEATHER MANUFACTURERS' RESEARCH ASSOCIATION

The British Leather Manufacturers' Research Association held its fortieth annual open days during May 3–5 at Milton Park, Egham, the Surrey mansion where the laboratories of the Association have been established for the past ten years. More than four hundred visitors attended, mostly from the industry, but including representatives of university departments, research associations, government departments and other bodies.

The Association, which was one of the earliest to be established under the Department of Scientific and Industrial Research scheme for co-operative research in industry, has an income of £65,000 p.a., and applies its effort in roughly equal proportions to background research, technological investigations and member services. Studies of the composition of skin have been maintained since Dr. Joane H. Bowes, the Association's chief biochemist, worked out the overall amino-acid composition of collagen some fifteen years ago; in this year's exhibition the decrease with increasing age of the animal in the proportions of serum and other non-collagenous proteins in the skin was shown. The Biochemistry Department is making a fundamental investigation (sponsored by the U.S. Department of Agriculture) on the mechanisms of the deterioration of leather by various agencies such as heat, moisture and perspiration. A survey of the rates of deterioration of different kinds of leather was shown, together with an exhibit of the more fundamental aspects of the work, which involve the use of continuous paper electrophoresis and liquid-phase chromatography, to identify the breakdown products of the protein fibres and the tanning agents, and the use of isotopic labelling, to follow the movement of tanning agents out of the protein phase.

In the Physics Department, under Dr. R. G. Mitton, work on waterproofing of leather was shown. While the intrinsic water-resistance of leather is adequate for many purposes, there are increasing demands for special leathers with improved performance. Results obtained with a variety of treatments designed to improve water-resistance without reducing the porosity of leather were shown. An important objective of the work of the Physics Department is to devise laboratory tests for assessing the complex physical properties of leather in its many uses; a number of test machines constructed in the Association's laboratories were exhibited. Performance trials under controlled conditions also prove valuable. Studies of the mechanical properties of collagen and leather fibres were also displayed. The properties of leather depend on those of its constituent fibres and on their mode of interweaving. An electrobalance for weighing very small fibres and an extensiometer for determining their stress/strain relation in different controlled atmospheres have been constructed at Milton Park for this work.

The Biology Department, under Dr. Mary Dempsey, is pre-eminent in the study of the fibre structure of skin; one of the items on show was the album of photomicrographs ("Hides, Skins and Leather under the Microscope"), published by the Association, which has had a wide circulation among investigators in other fields concerned with the structure of animal skins. Other exhibits showed the influence of abnormal skin conditions such as mycotic dermatitis, hyperpigmentation and melanomia, on the resulting leather.

In the Chemistry Department, under Dr. D. E. Hathway, exhibits summarized the work done during the past five years, which has contributed substantially to the understanding of biogenesis and structure of the condensed and the hydrolysable groups of natural organic tannins; the aromatization of glucose yields gallic acid and other phenolics (including ellagic acid formed by oxidation of gallic); these by esterification with glucose form the hydrolysable tannins, which are converted to condensed tannins by oxidation in the plant. A variety of non-tannin extractives from trees were also shown, for example, taxifolin and dihydropiceatannol from barks of native conifers (supplied by the Forestry Commission) and hydroxystilbenes from the heartwood of *Eucalyptus redunca*. The Chemistry Department is also responsible for work on leather dyeing, and has developed the application to leather of the 'Procion' range of dyestuffs introduced a few years ago by Imperial Chemical Industries, Ltd. These dyes combine with the substrate by a covalent link giving improved fastness in comparison with other types of dye, which in general become attached by less-specific links. The use of a resist, of the same chemical type, to modify the fixation of 'Procion' dyes on leather, was also shown. This material, now manufactured by Imperial Chemical Industries, Ltd., under the designation 'Lissatan *PR*', was first prepared in the Association's laboratories.

Enzyme treatments have been used by the leather industry for many years for softening skins before tanning, and proteolytic enzymes have been used to a very limited extent for loosening hair in the pre-tanning treatments. Mr. K. G. E. Wyatt demonstrated current work by the Association on the proteolytic treatment which, if it can be made practicable for full-scale operation, will have several operational advantages over the customary treatment with milk of lime and sodium sulphide, for hair-loosening. In the Chemical Engineering Department, under Dr. F. E. Humphreys, investigations on drying leather were displayed. The best drying conditions (air temperature, humidity and flow-rate) for combining fuel-economy and satisfactory leather characteristics have been worked out for the more important types of leather, and a simple drying tunnel with air re-circulation, suitable for most kinds of leather, has been devised. In many of the processes of leather manufacture, accurate control of simple physico-chemical factors such as *p*H value, electrolyte concentration and temperature is desirable and the Department is studying methods for making the necessary measurements inside revolving drums; continuous determination of *p*H value of the liquid in a drum was demonstrated.

Following Procter's application of the Gibbs–Donnan theory of membrane equilibrium to the gelatin/acid system, much work has been done by the Association and in other laboratories on the swelling of collagen in water mostly by acid or alkali, but the addition of any electrolyte, one ion of which can be fixed or adsorbed in the collagen phase, will set up a membrane equilibrium or modify an existing one. An application of this was shown by Mr. E. F. Nattrass in the use of a polymeric phosphate, the anion of which combines with collagen, to control the swelling in acid pre-tanning treatment, so that the maximum practicable leather thickness is obtained; but the swelling is kept below the level at which practical difficulties, such as retarded absorption of tanning agent, would occur. K. W. PEPPER

REACTOR FUEL ELEMENT TECHNOLOGY

A COURSE of ten lectures in reactor fuel element technology was given in the Department of Chemical Engineering at the Imperial College of Science and Technology, London, during February and March. The lecture series, which formed part of the postgraduate diploma course in nuclear technology (chemical), was designed to lay emphasis on the industrial problems of reactor fuel element technology and to appeal to scientists and technologists interested in the metallurgical aspects of nuclear power development. All the lecturers, who were from the United Kingdom Atomic Energy Authority, were specialists in their subjects and spoke from personal experience about the problems inherent in fuel element manufacture.

The course was arranged by the reader in nuclear technology (Mr. G. R. Hall) in collaboration with Mr. L. Grainger, chief metallurgist at the Atomic Energy Research Establishment, Harwell.

Mr. Grainger gave the introductory and concluding lectures. He described various types of reactor fuel element, the qualitative requirements of a satisfactory fuel element, and future developments in fuel element design and fabrication. In Mr. Grainger's opinion, progress in fuel element performance was now the most vital factor in the economic utilization of nuclear power; experimental irradiations would determine the rate of advance for some years to come.

Dr. J. F. M. Bishop, deputy head of laboratories at Springfields, discussed the theoretical evaluation of a fuel element. He outlined the general methods of procedure, illustrated by examples, and described the effects of irradiation and other factors which require consideration. The first stage in the evaluation of a fuel element is to see if it will endure for the proposed charge life under the conditions of stress and temperature imposed. If so, the effects of changes induced by irradiation are then considered in detail. During his second lecture, special attention was paid to ratcheting and irradiation creep.

Mr. J. Harper, head of laboratories, Springfields, described the Springfields manufacturing process from ore to machined bars for Calder and Central Electricity Generating Board fuel elements. The emphasis was placed on the metallurgical stages in the process. He pointed out that the efficiency of slag/metal separation in uranium billet production is a major factor in the quality of a fuel rod. Each fuel rod has its case-history recorded on a punched card.

Mr. D. O. Pickman, deputy head of laboratories, Springfields, described the design and manufacture of Calder-type fuel elements, assembly and testing procedure, and out-of-pile proving tests. In the course of his second lecture he reviewed performance experience in Calder and irradiation proving of Central Electricity Generating Board fuel elements. Out of the 90,000 fuel elements loaded up to mid-July 1959, only twenty-seven failures have been observed.

Mr. L. M. Wyatt, late deputy head of laboratories, Culcheth, and now with the Central Electricity Generating Board, described fuel elements for the advanced gas-cooled reactor and fast reactors. He considered the design and expected performance of these uranium dioxide fuels with stainless steel, beryllium and other canning materials. The design of similar fuels for light water and/or heavy water-cooled and moderated reactors was also briefly referred to. In his second lecture, Mr. Wyatt described fast reactor fuels and cans and expected operating conditions. He concluded by briefly comparing British, American and Russian fuel elements. Design drawings of the advanced gas-cooled reactor fuel elements aroused great interest.

Mr. H. Lloyd, leader of the Fuel Element Fabrication Group at Harwell, discussed the fabrication of *Dido*-type fuel elements including the Mark III version, and considered their application to power reactors. Possible variations and improvements in fuel materials and design were mentioned and comparison was made with similar American fuels. Although various power reactors employing plate-type fuel elements have been built in the United States, only design studies have so far been made in Great Britain. Mr. Lloyd displayed samples illustrating various stages in the fabrication of the *Dido* fuel element, and these aroused much interest.

The course was well attended and it was particularly pleasing to see about forty representatives from industry. Each of the lectures provoked a stimulating discussion. Although the lecturers would have liked to answer the questions put to them fully, they were occasionally prevented from doing so by commercial security regulations. This applied mainly to questions concerning throughput and costs.

In view of the interest the lectures aroused, it is hoped to hold a similar series early in 1961.

THE LEVERHULME TRUST

REPORT FOR 1956–58

THE third report of the Leverhulme Trust*, which covers the period 1956–58, in which commitments of £593,000 were undertaken, is the first of a series of triennial reports. Of this sum, 33 per cent was devoted to universities and centres of higher education, 8 per cent to learned societies, 30 per cent to medical research and 12·5 per cent to grants to individual scholars. Of those to British universities, the largest grant, £30,000, was to Liverpool for fellowships in general research, mathematics, physics and town planning. The University of Manchester received £14,900 for research fellowships and studentships at Jodrell Bank Experimental Station, Nuffield College, Oxford, £14,100 for a study of industrial relations with particular reference to the history and problems of the trade union movement, collective bargaining, the appointment and responsibilities of shop stewards and so forth, and St. Antony's College, Oxford, £12,500 for the study directed by Lord Ismay's committee on the changes in the international status of the United Kingdom since the Second World War and of its position as a Colonial power. £6,000 went to Birkbeck College, London, for research by Dr. N. Pevsner on the buildings of England, and £16,950 to the London School of Economics for miscellaneous scholarships and research awards. The University of Leeds received £7,500 for a research fellowship, scholarship and lectureship in the history and philosophy of science; the Institute of Commonwealth Studies, London, £6,000 for research fellowships in economic development in the Colonies; and the University College of Rhodesia and Nyasaland £28,000 to finance inter-collegiate conferences.

Of the grants to learned societies, research institutions, etc., those of £4,500 to the British Association for the Advancement of Science for an inquiry, under Sir Patrick Linstead's direction, into the broadening of the education of those intending to become scientists and technologists, and of £8,400 to Political and Economic Planning for a study of the effects of economic planning on governments and administration may be mentioned; in medical research, the Royal College of Surgeons received £42,000 for research fellowships and scholarships in dental surgery; the Middlesex Hospital Medical School, £35,000 for scholarships at the Institute of Clinical Research; the London School of Hygiene and Tropical Medicine, £14,000 for research in industrial medicine over four years; the London College of Osteopathy, £12,500 for scholarships; the Institute of Laryngology and Otology, £9,100 for research fellowships; King's College Hospital Medical School, University of Durham, £8,700 for a research fellowship and the Department of Education of the Deaf, University of Manchester, £2,000 for research in connexion with the design of hearing aids. St. Mary's Hospital Medical School received £9,500 for biochemical research.

SICKLE-CELL ANÆMIA

INVESTIGATIONS into sickle-cell anæmia in Nigerian children by R. G. Hendrickse, of University College, Ibadan, shows significant differences from experiences recorded by American research workers (*Central African Journal of Medicine*, 6, No. 2; February 1960).

In Africa the age at onset of severe symptoms is earlier; anæmia tends to be more severe; the incidence of splenomegaly is higher, and spleens seem to be larger; gross hepatomegaly and evidence of hepatic dysfunction generally occur at an earlier age; limb swellings, especially those involving the hands and feet, are common in the early years of life, whereas they are rarely reported by American authors; radiological evidence of bone involvement is more frequent and the ultimate prognosis appears to be worse.

These differences in general reflect the more rigorous conditions under which children live in Africa, but certain features of the disease may be attributed to specific environmental factors. Spleen sizes are probably related to endemic malaria, and the earlier onset of liver dysfunction may be related to dietary protein deficiency. The characteristic swellings in the hands and feet of African infants may well result from the customary manner in which African mothers carry their babies. The child is placed astride the mother's back, its legs encircling her waist. The position is maintained by a wrapper which covers the child and is tied in front of the mother. In this position the child's limbs are pinioned to the mother and subjected to steady pressure which probably slightly impairs the peripheral circulation. Such impairment, while of no consequence in normal children, may be sufficient in sickle-cell anæmia to provoke intravascular sickling in the extremities, with resultant capillary blockage and reactionary swelling.

While differences in the clinical picture of sickle-cell anæmia in Africa and America may be attributed to environmental factors, the apparent difference in the severity of the disease in different parts of Africa cannot be readily explained in the same way. Differences in the age incidence in the Belgian Congo and Nigeria are of particular interest. In the Belgian Congo more children show signs of the disease between the ages of three months and one year than at any other period. It has been shown that for infants in hyperendemic malarial areas the mean parasite-rate rises from about 2 per cent at three months to 80 per cent at one year. In the Belgian Congo, therefore, it appears that the period during which children acquire their first infection with malaria coincides with the age during which sickle-cell anæmia is most frequently diagnosed. This suggests that malaria should be considered as a possible factor determining the age at which sickle-cell anæmia presents in the Belgian Congo. Another possible explanation of these age relationships is that some of the cases in the Belgian Congo were examples of primary malarial anæmia in persons with the sickle-cell trait. The clinical and hæmatological findings in such cases can closely simulate those encountered in sickle-cell anæmia. None of the cases reported from the Belgian Congo by the Lambotte-Legrandes was confirmed by electrophoretic studies of the hæmoglobin.

The apparent differences in the clinical manifestations of sickle-cell anæmia in different parts of Africa merit closer study. There are no grounds at present for contending that these differences have a genetic basis, though this possibility should be borne in mind.

ORIGIN OF TEKTITES

Solar Furnace Glass

TO explore the suggestion that tektites are formed by fusion of terrestrial material we have fused some rock samples in a solar furnace. These samples were collected from the regions where tektites have been found in Texas and Georgia in the United States. The Texas sandstone was taken from a stratum in the Wellborn formation in which embedded tektites reportedly had been seen. The black top-soil was taken from a location where tektites had been found in Grimes County, Texas. The Georgia sandstone was collected immediately below the top soil near a place where several tektites were discovered.

The sediments were fused in the solar furnace of the U.S. Army Quartermaster and Engineering Center, Natick, Massachusetts[1], made available to us through the courtesy of Mr. Eugene S. Cotton. At the time of the experiment, November 20, 1959, 1000 a.m., E.S.T., the flux of energy at the focus was 83 calories cm.^{2} sec.$^{-1}$, as determined from the rise in temperature of a blackened metal disk. Each specimen was placed in a graphite crucible in the form of a plug. To make the plug the material was crushed, mixed with water, moulded and then baked at a temperature of approximately 150° C. We added 5 per cent by weight of ferric oxide to samples 2 and 3. Sample 1 weighed 100 gm., samples 2–5 weighed 50 gm.

The exposure time of the samples varied from 59 to 240 sec., the Georgia samples being heated for a longer period of time than those from Texas. Immediately after the water-cooled shutter of the solar furnaces opened, vapour could be seen rising from the sediment, while the front surface of the material became luminous and reached white heat in approxi-

Table 1

Sample	Exposure (sec.)	Weight loss (per cent)	Weight glass (gm.)	Fusion (erg/gm.)
(1) Texas sandstone	59	11·1	20·9	$1{\cdot}9 \times 10^{11}$
(2) Texas sandstone	72	13·6	14·9	$1{\cdot}7 \times 10^{11}$
(5) Texas topsoil	70	11·6	10·2	$2{\cdot}3 \times 10^{11}$
(3) Georgia sandstone	120	20·6	14·6	$2{\cdot}9 \times 10^{11}$
(4) Georgia sandstone	240	20·4	28·2	$2{\cdot}9 \times 10^{11}$

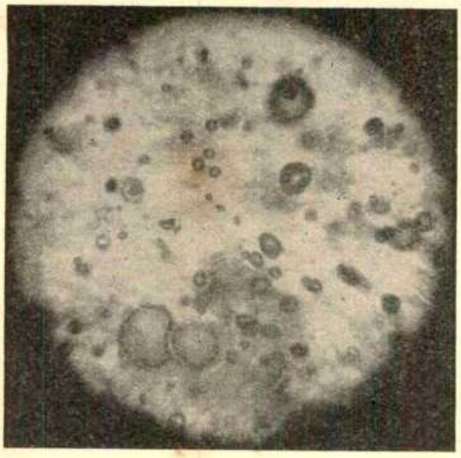

Fig. 1

mately 10 sec. Bubbling began after approximately 20 sec. followed immediately by a forward slumping of the viscous material. In sample 1, where the glass was allowed to pour out of the radiation beam, the drips stiffened and solidified within 2 or 3 sec. The results of the experiment are summarized in Table 1.

It can be seen that the Texas material decreased in weight by 12 per cent and the Georgia material by 20 per cent owing to the vaporization of water and other constituents. The energy required to fuse 1 gm. of glass varied between $1 \cdot 7$ and $2 \cdot 9 \times 10^{11}$ ergs gm.$^{-1}$. After fusion each sample showed a glassy surface with large bubbles, underneath which was a hard porous layer. There was also a considerable quantity of soft, dry material that had not been fused. The specific gravity of the glass droplets, including bubbles, from sample 1 was $1 \cdot 980$ gm.$^{-3}$. The scoriacious layer was considerably lower in density; but no measurements were made on this or the partially fused material.

There is, of course, no definite temperature at which glass melts, and no definite latent heat of fusion. We may define the heat of fusion as the energy required to raise the temperature of 1 gm. of silica glass from 20° C. to 2,000° C., at which temperature the glass would be liquid and incandescent. This heat of fusion may be estimated by extrapolating the tabulated values of specific heat[2] and performing an integration. We find the heat of fusion to be $2 \cdot 1 \times 10^{10}$ erg/gm. The values determined in the solar furnace experiment are ten times higher, the difference being largely due to the losses of heat involved in the fusion process by radiation, conduction, convection and vaporization of material. Nevertheless the effect of heat of fusion as determined here is of considerable interest to any theory of the formation of tektites by external application of heat because it is the value one might expect when radiation and other heat losses occur.

A photomicrograph (reduced to $\frac{1}{2}$) of a thin section of the solar furnace glass, taken with crossed polarization at × 60, is shown in Fig. 1. The glass showed flow lines and bubbles, but we have, as yet, found no evidence for lechatelierite particles. Light was still transmitted through the specimen when viewed with crossed polarization, indicating that the solar furnace glass was under considerable strain. Texas and Philippine tektites, on the other hand, show extinction when viewed with crossed polarization. The tektite glass may have cooled more slowly than solar furnace glass, or may have annealed at ordinary terrestrial temperatures over the long period of time that it had rested in the sediments.

Taking the effective heat of fusion as 2×10^{11} ergs/gm., one finds that approximately 5 min. must elapse before a sphere some 2 cm. in diameter could be fused by passage through the upper atmosphere at a velocity of 10 km./sec. Single tektites could not be fused in the atmosphere, therefore, since an object of this size would decelerate in a matter of a few seconds. There is sufficient energy for tektites to form as drops from the surface of a much larger object, but glass objects have never been recovered from the 590 stone falls already observed[3]. A meteorite with velocity of 20 km./sec. has a kinetic energy of 2×10^{12} ergs/gm. Thus a meteorite of mass m striking the Moon would produce about $10\,m\,(1 - x)$ gm. of glass, where x is the fraction of energy dissipated in shock waves, crater formation and vaporization of the meteorite. A study of terrestrial craters shows that x is close to unity. Only a small quantity of glass would be produced on the Moon and only a portion of this would reach the Earth. Nor do the craters seem to be deep enough for the meteorite to have uncovered molten material below the Moon's crust. It is more probable for an energy of 2×10^{11} ergs/gm. to be supplied by terrestrial phenomena such as volcanic activity or lightning.

This work was made possible by a research grant from National Aeronautics and Space Administration.

High-Temperature Fusion of Possible Parent Materials for Tektites

BAKER[1] has recently presented very strong evidence for an extra-terrestrial origin for australites and, by implication, for all true tektites. Once an extra-terrestrial origin is established, then the localized distribution of tektites (particularly the australites) is most readily explained if they have originated close to the Earth[2,3]. In these circumstances, the most likely origin for tektites is that they are portions of the Moon's crust which were fused during large meteorite impacts and then ejected from the lunar surface to fall on the Earth[4].

Certainly as far as their very young ages, most physical properties and terrestrial distributions are concerned, a lunar origin for tektites would seem to be preferred. However, the most serious stumbling block to this theory[3] is the rather unusual composition of tektites, which some authors consider shows that tektites are most likely to be fused sediments[5]. The most probable terrestrial sediment from which tektites might have formed is a shale, and if terrestrial-type shales are the only likely parent materials then a lunar origin would seem to be out of the question. On the other hand, other authors have shown that certain acid igneous (granitic) rocks could well have been suitable parent materials for the formation of tektites[6]. In view of the strong possibility that igneous rocks of granitic composition may exist on the lunar surface, then a lunar origin for tektites would not be unlikely in these circumstances. Clearly it is extremely important to establish what rock types are suitable parent materials for tektites.

Although some types of terrestrial shaly sediments[5] and some types of acid igneous rocks[6] have compositions similar to those of tektites, the composition of the average tektite shows considerable differences from both the average terrestrial shale and the average granite (Table 1), so that neither appears to be an entirely satisfactory parent material. Of course, the assumption that a lunar granitic rock would have the same composition as the average granite found in the Earth's crust at the present day is unlikely to be completely true since many terrestrial granites are probably granitized sediments, and almost certainly all terrestrial granites have assimilated varying amounts of sedimentary and other rocks. However, if there is some material of granitic composition on the lunar surface, it would most likely have formed as a differentiation product during a partial or complete melting of the Moon. There is some geological evidence which suggests that the Earth's primitive continental masses were composed of granitic material formed during an early-stage partial or complete melting of the mantle, although no uncontaminated samples of this material are available for comparison with tektites. In the search for possible parent material for tektites, another approach would be to compare possible lunar surface rocks with acid igneous rocks which are believed to form as the result of differentiation of more basic magmas in the Earth's crust. In these circumstances, perhaps, a suitable rock type would be the acid granophyres often found associated with basic magmas, and which many petrologists believe are acid differentiates of these magmas, although some granophyres may be sedimentary and other rocks mobilized during intrusion of the magmas. Analyses of thirty-five acid granophyres from the available literature have been averaged in Table 1, and in many ways these rocks do appear to be more suitable parents for tektites than the average granite, particularly in that the total iron content of the average granophyre is much closer to that of the average tektite. However, the data in Table 1 also indicate that the sodium monoxide and potassium monoxide contents of the granophyres are higher, and the calcium oxide and magnesium oxide contents lower, than that of the average tektite.

In all comparisons of tektites with the various possible parent materials, the tacit assumption has been made that the process of tektite formation has involved only simple melting, so that both parent rock and tektites would have the same overall composition. However, if tektites have, in fact, formed at the site of large meteorite impacts then temperatures up to 100,000° C., far in excess of simple melting temperatures, have operated over considerable areas around the impact site[10]. Under these conditions it would seem likely that selective volatilization of certain elements could have taken place during the formation of tektite glass, so that parent rock may well have had a composition significantly different from that of the tektite glass. It is reasonable to assume that the relative volatilities of the elements during the formation of tektites would correspond to the boiling points of their normal oxides, or, where boiling points are not available, can be interpolated from their melting points. Consequently, the order of volatility of the major constituents of tektites might be expected to be approximately magnesium oxide, calcium oxide < alumina < silica, ferrous oxide < sodium monoxide, potassium monoxide, so that it might be predicted that tektite glass would be impoverished in sodium monoxide and potassium monoxide, and enriched in magnesium oxide, calcium oxide and possibly also alumina relative to the parent rock. If the concentrations of the major elements have changed in this way during the formation of tektites, then the data in Table 1 indicate that although the average shale is not a suitable parent material for tektites, the acid igneous rocks could perhaps be converted into tektite material.

Table 1. AVERAGE COMPOSITION OF TEKTITES, TERRESTRIAL SHALES, GRANITES, AND ACID GRANOPHYRE DIFFERENTIATES OF BASIC MAGMAS

	I Average tektite	II Average shale	III Average granite	IV Average acid granophyre
SiO_2	73·4	63·9	72·5	73·6
Al_2O_3	12·4	17·0	13·9	12·6
Fe_2O_3	0·6	4·4	0·9	2·1
FeO	4·4	2·7	1·7	1·9
MgO	2·1	2·7	0·5	0·4
CaO	2·5	3·4	1·3	1·2
Na_2O	1·3	1·4	3·1	3·4
K_2O	2·3	3·6	5·4	4·2
TiO_2	0·9	0·7	0·4	0·4
P_2O_5	—	0·2	0·2	0·1
MnO	0·1	tr	0·1	0·1

I, average composition of 62 tektites calculated from data collected by Barnes (ref. 7).

II, average composition of 78 terrestrial shales, recalculated on a water and carbon dioxide free basis from Clarke (ref. 8).

III, average composition of 72 calc-alkaline granites (ref. 9).

IV, average composition of 35 acid granophyre differentiates of basic magmas calculated from published analyses.

To establish whether high-temperature fusion of granitic rocks would form glasses the compositions of which were changed in this way, a powdered granite was subjected to a series of fusions in a solar furnace at temperatures within the range 1,500–3,000° C. A solar furnace was chosen for the experiments because it provides relatively high temperatures simply, quickly and cheaply and with no possibility that the melts could be contaminated by reaction with an enclosing crucible. The granite sample chosen was collected at Fenton, Northern Territory, Australia, crushed to –100 mesh and placed in a large porcelain crucible at the focus of a solar furnace which was situated in the grounds of the University of New South Wales at Broken Hill, New South Wales. Only a small, centrally situated area of the surface of the granite sample was fused during each run, and in this way small glassy buttons, 3 cm. across, 0·8 cm. deep, and weighing about 13 gm., were formed.

The first glassy buttons formed by melting the original granite sample (melting stage 1) were found to contain a considerable amount of unmelted material. To ensure complete melting, a number of melting stage 1 buttons were prepared from the powdered granite, and then these buttons were crushed and their powder used to form a further series of buttons (stage 2). Enough material for a complete rock analysis was kept of each melting stage and the process was continued until samples at each of five stages of melting were prepared, after which no material was available for further heating. Careful analyses were carried out by A. J. Easton on samples of the original granite and glass from melting stages 3, 4 and 5, but since only small amounts of material were available for analysis, only single determinations of each constituent could be made. The uncertainty of a single determination of any constituent is given by the relative deviation of that constituent calculated for the particular analytical method used. These data had previously been determined for each constituent from replicate analyses of a standard granitic rock (for example, silica, 0·2 per cent relative deviation; alumina, 1·4 per cent; ferrous oxide, 0·6 per cent; magnesium oxide, 3·3 per cent; calcium oxide, 3·1 per cent; sodium monoxide, 0·7 per cent; potassium monoxide, 2·0 per cent). On the basis of these uncertainties the results of the analyses of the granite and the glasses (Table 2) are strong evidence for the progressive loss of sodium monoxide and potassium monoxide, relative enrichment in magnesium oxide, calcium oxide and alumina, and little change in silica and ferrous oxide during progressive high-temperature meltings of granitic rock. The elemental fractionations observed in these experiments have taken place at temperatures of only about 2,000° C. so that at the site of meteorite impacts where temperatures up to 100,000° C. have operated there is ample opportunity for extensive fractionation of the constituent elements in the directions established in these experiments. It may be concluded that rocks of general granitic composition, and particularly the acid granophyre differentiates of basic magmas, are suitable parent materials for tektites if they have formed at relatively high temperatures at the site of meteorite impacts. This conclusion is not at all inconsistent with a lunar origin for tektites.

Table 2. CHANGE IN COMPOSITION OF GLASSES FORMED BY THE PROGRESSIVE HIGH-TEMPERATURE FUSION OF A GRANITIC ROCK *

	Granite (Fenton, Northern Territory, Australia)	Glass		
		Stage 3 Melting	Stage 4 Melting	Stage 5 Melting (partial analysis)
SiO_2	75·96	75·77	75·48	—
Al_2O_3	12·52	13·07	13·23	—
FeO	2·27	2·21	2·22	2·23

CaO	0·74	0·79	0·79	—
Na_2O	2·19	2·00	1·99	1·94
K_2O	5·38	5·11	5·05	5·05
TiO_2	0·24	0·25	0·25	0·26
P_2O_5	0·07	0·10	0·11	0·15
MnO	< 0·005	< 0·005	< 0·005	< 0·005

* All analyses recalculated on a water-free basis and total iron recalculated as ferrous oxide. Analyst, A. J. Easton.

These experiments, together with new data on the distribution of certain trace-elements in tektites, will be discussed at greater length in a paper to be published elsewhere. The solar furnace fusions were very kindly carried out by A. Segal, and the co-operation of Prof. C. J. Milner, University of New South Wales, is gratefully acknowledged in making the furnace available for these experiments.

POLYINOSINIC PLUS POLYCYTIDYLIC ACID: A CRYSTALLINE POLYNUCLEOTIDE COMPLEX

By Dr. DAVID R. DAVIES

National Institute of Mental Health, Bethesda, Maryland

RECENT investigations by Doty *et al.*[1] have demonstrated the existence of secondary structure within the ribonucleic acid molecule in solution. Although it seems evident that the secondary structure is the result of hydrogen bonding between the bases, the structural arrangement of the molecule is not known. X-ray diffraction studies on a variety of natural ribonucleic acids were carried out by Rich and Watson[2]. Although the diffraction patterns obtained were poorly oriented, they were essentially the same regardless of the source of the ribonucleic acid, and were identified as characteristic of helical material. It is presumed that the X-ray diffraction pattern is produced by the same secondary structure as observed in solution.

The synthetic polyribonucleotides, polyinosinic acid (poly I) and polycytidylic acid (poly C) have been shown to interact in solution to form a 1 : 1 complex[3], poly (I + C). X-ray fibre diffraction patterns obtained from 1 : 1 mixtures of the polymers were found to resemble closely those of natural ribonucleic acid. The structure giving rise to these patterns we shall call the *B* form of poly (I + C). Extensive model building has failed to provide a satisfactory explanation for this poly (I + C) diffraction pattern, and it was felt that this was partly because of the poor orientation of the fibres, leading to uncertainties in the dimensions of the molecule.

Attempts have therefore been made to obtain better diffraction patterns of this complex, and in the course of this investigation fibres were obtained which exhibited a new type of pattern (Fig. 1). This differs from the *B* pattern in that the molecules are now packed in a crystalline array with somewhat different spacings. The layer-line spacing for the crystalline material is 35 Å., and the unit screw dimensions consist of a translation of 3·0 Å. and a rotation of 31°. This crystalline form we shall call the *A* form of poly (I + C).

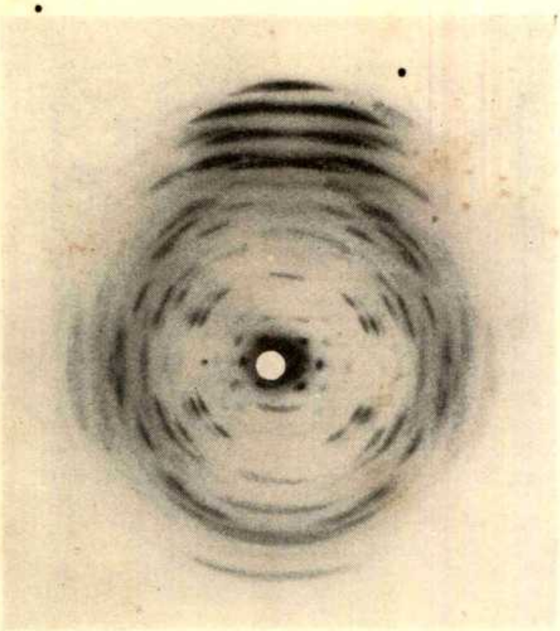

Fig. 1. X-ray diffraction photograph of the *A* form of poly (I + C). The fibre is tilted to show more clearly the upper layer lines on and near the meridian

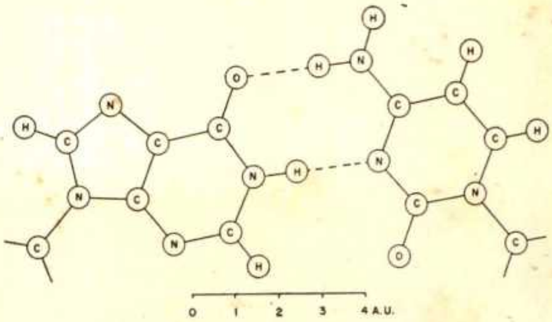

Fig. 2. The arrangement of the bases for the *A* form of poly (I + C)

Poly I was polymerized with polynucleotide phosphorylase isolated by methods previously described[4]. It was dialysed successively against 0·01 *M* versene at *p*H 7·0, 0·01 *M* sodium chloride, and ion-free distilled water. Poly C was a gift from Dr. Leon Heppel. It had been dialysed against distilled water.

The polymers were dried and weighed. 3·0 mgm. of poly C and 3·3 mgm. of poly I were then dissolved in 1 ml. of 0·01 *M* sodium cacodylate buffer at *p*H 6·7. They were mixed thoroughly and the solution lyophilized. Fibres were then pulled from small amounts of the lyophilized material dissolved in distilled water. Examination of these fibres (of thickness around 0·1 mm.) showed them to be highly negatively birefringent with $\Delta n < -0{\cdot}05$.

X-ray diffraction photographs of these fibres were taken in a closed fibre camera with specimen to film distances of 3·0 and 4·0 cm. Helium was blown through the camera to reduce the amount of scattered radiation, and the relative humidity of the helium was controlled by passing it first through a gas dispersion tube placed in a saturated salt solution.

Model building studies indicate that this crystalline diffraction pattern (Fig. 1) can best be interpreted in terms of a deoxyribonucleic acid-like structure. The complex formed is a two-stranded helical structure with the ribose phosphate backbones of the two strands running in opposite directions as in the Watson and Crick structure of deoxyribonucleic acid[5]. The hypoxanthine bases of one strand form two hydrogen bonds with the cytosines of the opposite strand (Fig. 2) compared with three between the guanine–cytosine pair of deoxyribonucleic acid.

The intense non-meridional layer lines with spacings between 3 and 4 Å. suggest that the bases are not perpendicular to the fibre axis, but are tipped at an angle of about 7° to the horizontal. This amount of tipping would still enable the fibre to possess strong negative birefringence.

A peculiar feature of the diffraction pattern is the absence of strong intensity close to the meridian on the second and third layer lines. This may be tentatively accounted for by the presence of sodium cacodylate in the fibres. The strongly scattering cacodylate ion placed regularly in the crystal lattice can account for the observed absence of strong intensity. This region of the diffraction pattern is very sensitive to the ionic content of the fibre. If magnesium chloride is allowed to diffuse into the fibre the main features of the diffraction pattern are retained, but the near meridional region of the second layer line now becomes strong relative to the first layer line, giving an intensity distribution on the first three layer lines which is very similar to that observed for the *A* form of deoxyribonucleic acid.

Fibres of deoxyribonucleic acid show a reversible humidity-controlled transition from the *A* to the *B* form. Since it was suspected that the *A* and *B* forms of poly (I + C) bore a similar relation to each other as the *A* and *B* forms of deoxyribonucleic acid, attempts were made to obtain such a transition from the crystalline poly (I + C) fibres. However, over the range of 20–90 per cent relative humidity there was no major difference in the diffraction pattern. At 98 per cent relative humidity the fibres dissolved and at 0 per cent relative humidity the pattern became amorphous, but could be changed back to the crystalline *A* form on raising the humidity.

However, from poorly oriented fibres it was possible to obtain a non-crystalline pattern which was similar in many respects to the *B* pattern. The innermost regions of these patterns were weak in intensity, and this again might be due to the presence of sodium cacodylate. Well-oriented fibres inevitably crystallized.

The fact that the *A* and *B* forms may be found in fibres pulled under almost identical conditions suggests that the *B* form of poly (I + C) (and therefore, presumably, the helical regions of ribonucleic acid) may have the same configuration of the base pairs as the *A* form. However, direct evidence for the structure of the *B* form is not at present available and will have to await the production of better X-ray fibre patterns of this form. Further investigations are now being carried out to establish reproducible conditions for the production of the two forms of poly (I + C).

I wish to thank Dr. Leon Heppel for the gift of some poly C. I am also indebted to Drs. F. H. C. Crick and Martin Gellert for many stimulating discussions and suggestions.

A NEW TYPE OF AUTOXIDATION REACTION

Cause of the Instability of Cytochrome c Reductase

THE majority of flavoprotein enzymes are reasonably stable ; two, however, show an exceptional degree of instability, which makes their purification and study difficult. Bach, Dixon and Zerfas[1] found that the lactate dehydrogenase of yeast was so highly unstable as to prevent them from completing its purification, although Appleby and Morton[2] later succeeded in crystallizing it. The cytochrome *c* reductase of heart muscle is likewise very unstable, as has been noted by a number of workers since its first isolation by Mahler, Sarkar, Vernon and Alberty[3].

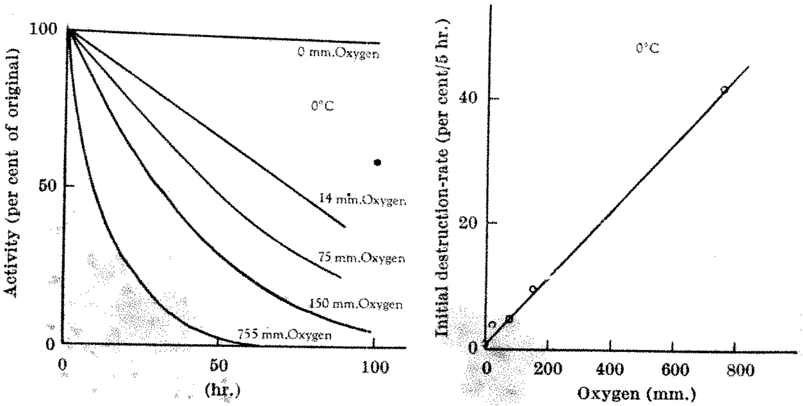
We have investigated the cause of the instability of the cytochrome reductase of pig heart. Simultaneously and independently, Prof. Morton *et al.* have studied the instability of the yeast lactate dehydrogenase, as reported in the following communication. It will be seen that the instability of both enzymes is due to the same cause, namely, a new type of autoxidation of the flavoprotein.

We find that cytochrome reductase, either in crude extract or purified by the method of Mahler *et al.*[3] or by other methods, has a half-life at room temperature of about 5 hr., and even at 0° it is markedly unstable. In unsuccessful attempts to stabilize the enzyme we have tested the effect of adding a considerable number of substances which are known to stabilize other enzymes, or which for various reasons might have been expected to prevent the inactivation. Albumin, glycerol, sucrose, histidine, glutathione, catalase, cytochrome *c*, reduced coenzyme I, cyanide, versene, dipyridyl, ammonium sulphate in high concentrations, tocopherol, chloroacetophenone, ferrous or ferric salts, riboflavin, flavin mononucleotide and flavin-adenine dinucleotide had no significant stabilizing effect ; alterations of *p*H were also ineffective.

The instability was finally traced to a reaction between the enzyme itself and oxygen, resulting in an irreversible inactivation with release of the flavin group from the protein. Removal of oxygen renders the enzyme stable : if a solution of the enzyme is divided into two portions, one is placed in an open test-tube and the other in an evacuated Thunberg tube, and both are kept at 0° for 4 days, the former is found to be inactive while the latter suffers no loss of activity. The inactivation in the presence of oxygen is accompanied by the appearance of the typical fluorescence of free flavin and under certain conditions, with strong solutions of purified enzyme, by the formation of a white protein precipitate.

Fig. 1*a* shows a series of inactivation curves with different oxygen pressures at 0°, from which it is clear that the rate of inactivation is proportional to the oxygen pressure (Fig. 1*b*). Fig. 2 shows the dependence on temperature, with a constant oxygen pressure (air) ; the Q_{10} is about 2·5, showing that the inactivation is not due simply to denaturation of the enzyme.

The results suggest that the protein part of the enzyme contains some autoxidizable group which is connected with the binding of the prosthetic flavin group, that this group exists in the reduced form in the intact enzyme, but that when the group becomes oxidized by oxygen the protein can no longer bind the flavin. The state of oxidation of the flavin group itself seems to be immaterial ; the inactivation occurs at about the same rate in the presence of reduced coenzyme I (which would keep the flavin reduced) as in the presence of cytochrome *c* (which would keep it oxidized).



(*a*) (*b*)

Fig. 1*a* and b. Effect of oxygen pressure on rate of inactivation of cytochrome reductase at 0° C.

The nature of the autoxidizable group remains undetermined. —SH groups come to mind, but such groups in other proteins are not nearly so sensitive to oxygen ; moreover the addition of glutathione (which should keep —SH groups reduced) fails to stabilize the enzyme. The enzyme contains some iron, which might catalyse the autoxidation of —SH groups, but if so cyanide, versene or dipyridyl would be expected to inhibit the inactivation, which is not the case. No uptake of oxygen could be measured during the inactivation, but this was to be expected. Assuming that 1 atom of oxygen is required per molecule of enzyme (m.w. 80,000, with 1 flavin group per molecule), as much as

5 mgm. of the pure enzyme would take up less than 1 μl. oxygen.

The inactivation is not due to the destruction of a factor which is necessary only for the reduction of cytochrome *c*; in other words, it is not merely a conversion of cytochrome reductase into diaphorase as suggested by Mahler[4] as a possible origin of diaphorase. All activity of cytochrome reductase (including its diaphorase activity) disappears in air, while that of diaphorase itself (which has no cytochrome reductase activity) is quite unaffected, as shown in Table 1. The instability of cytochrome reductase towards oxygen contrasts markedly with the stability of the flavoprotein diaphorase, obtained from the same tissue, which suffers no loss of activity on exposure to 4 atmospheres of oxygen for some hours at 38° (ref. 5).

Table 1. COMPARISON OF STABILITIES OF DIAPHORASE AND CYTOCHROME REDUCTASE

(Activities in arbitrary units)

Time of standing in air at room temperature	Diaphorase tested with indophenol	Diaphorase tested with cytochrome *c*	Cytochrome reductase tested with indophenol	Cytochrome reductase tested with cytochrome *c*
0	80	0	725	540
18 hr.	80	0	0	0

In addition to the inactivation by oxygen described above, cytochrome reductase is also inactivated by light, and for this oxygen is not required. Even the ordinary lighting conditions of the bench are sufficient to bring about appreciable inactivation. In all the above experiments the enzyme solutions were kept in darkness.

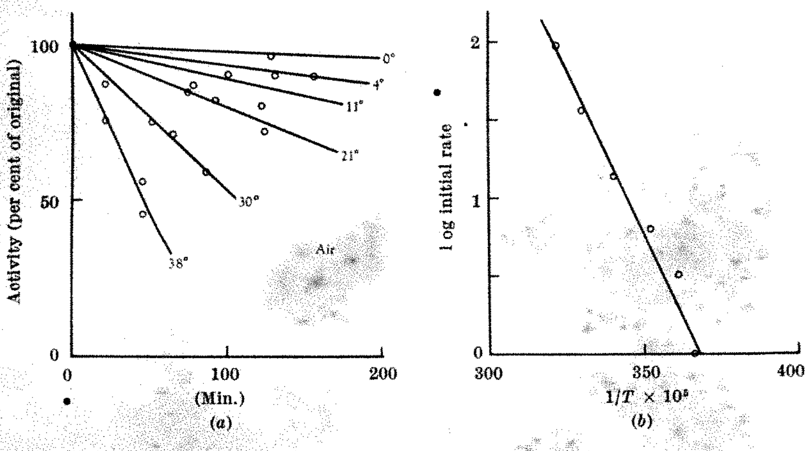


Fig. 2*a*, Inactivation of cytochrome reductase in air at various temperatures; *b*, Arrhenius plot of inactivation of cytochrome reductase in air, from results of Fig. 2*a*. Initial rate is taken as percentage loss in 40 min., corrected for differences in molarity of dissolved oxygen at different temperatures

It is possible that the inactivation of cytochrome reductase by oxygen may be important in connexion with the 'oxygen poisoning' produced by breathing oxygen at pressures exceeding 1 atmosphere, which has been ascribed to damage to the respiratory system of the tissues. Dickens[5] studied the stability to oxygen of several respiratory enzymes, the most sensitive proving to be the succinate dehydrogenase, with a half-life of 3 hr. at 38° with 1 atmosphere of oxygen. This, however, is far less sensitive than cytochrome reductase, which has a half-life of only 6 min. at this temperature and pressure of oxygen.

Flavin Dissociation and Inactivation of Cytochrome b_2 by Oxygen

CYTOCHROME b_2, the L(+) lactate dehydrogenase of baker's yeast[1], is rapidly inactivated in the presence of air[1-4]. The inactivation occurs in the presence of substrate, and also with added hydrogen peroxide, and is decreased when catalase is added[2,3,5]. Hydrogen peroxide is not formed in any large amounts during short-term aerobic oxidation of lactate by cytochrome b_2 (ref. 5). Cytochrome b_2 is inactivated by cupric ion and by the sulphydryl reagent *p*-chloromercuribenzoate, as well as by oxygen[2]. With all these reagents, the enzyme becomes fluorescent. The fully active enzyme, which contains both riboflavin phosphate and protohæm as prosthetic groups, is not fluorescent[1,3,6]. The inactivation caused by oxygen or by cupric ion is apparently irreversible. Neither monoiodoacetate (10^{-2} *M*)[6] nor iodoacetamide (10^{-3} *M*)[7] causes any substantial inhibition or appearance of fluorescence at neutral *p*H values. It has been proposed that the flavin of cytochrome b_2 is bound to the enzyme by a sulphydryl group of the protein, and that this 'masked' group does not react with iodoacetate or iodoacetamide[2,4]. The following observations give further support to this hypothesis and suggest that inactivation by oxygen is due to rapid oxidation of protein thiol groups to form disulphide bonds. Unless otherwise specified, solutions were equilibrated with commercial 'oxygen-free' nitrogen and all manipulations were carried out in an atmosphere of this gas. Traces of oxygen were probably present.

Cytochrome b_2 sedimented in the 'Spinco' analytical ultracentrifuge as a single component ($S^0_{20,w}$ = 8·36 svedberg units) with a symmetrical boundary. The solution above the boundary was colourless and non-fluorescent. When the same enzyme solution was briefly exposed to air, and re-examined in the ultracentrifuge, two new components ($S_{20,w}$ approx. 11 and 15 svedberg units respectively) were observed in addition to the component mentioned above.

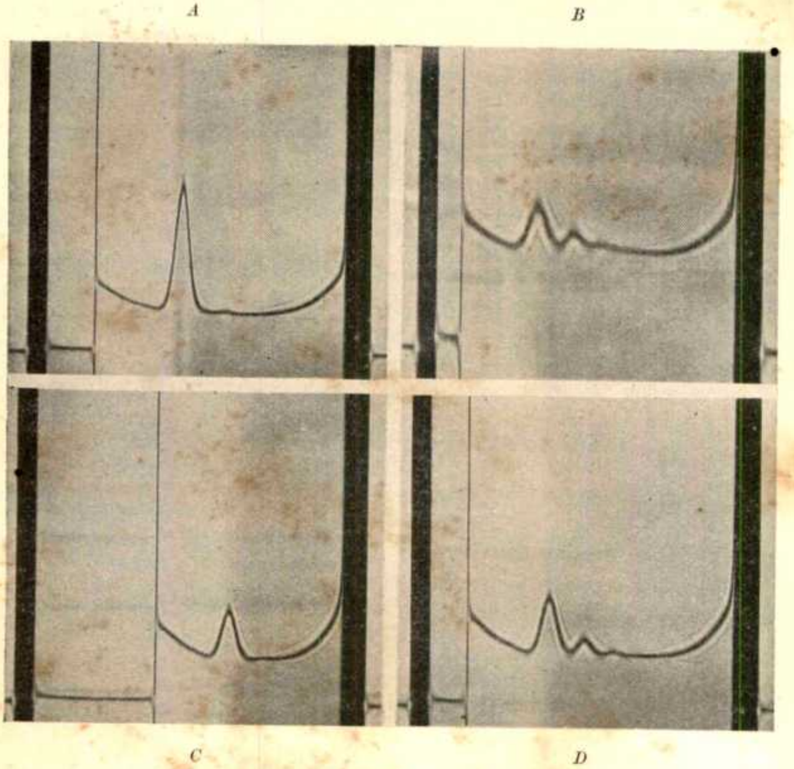

Fig. 1. Sedimentation behaviour of cytochrome b_2. Recrystallized cytochrome b_2 (0·4 to 1×10^{-4} M hæm) in 0·3 M sodium lactate, 0·05 M tetra-sodium-pyrophosphate; ethylene diamine tetra acetate, 10^{-4} M; adjusted to pH 6·8 with hydrochloric acid; ionic strength, 0·63; temperature, 2°–6° C. *A*, Under anaerobic conditions; *B*, the same preparation after brief exposure to air; *C*, preparation treated with 1×10^{-4} M p-chloromercuriphenylsulphonate and then exposed briefly to air; *D*, preparation exposed briefly to air and then p-chloromercuriphenylsulphonate (1×10^{-4} M) added. The photographs were not taken at equivalent times of centrifugation

The supernatant was yellow and had a characteristic flavin fluorescence (Fig. 1).

The addition of p-chloromercuriphenylsulphonate at about 10^{-4} M to a freshly prepared solution of enzyme (approx. $0·7 \times 10^{-4}$ M hæm) resulted in the appearance of strong flavin fluorescence after about 20 min. The enzyme sedimented as a single component with approximately the same sedimentation coefficient as intact cytochrome b_2 at the same concentration, and the supernatant was yellow and strongly fluorescent. When the enzyme treated with p-chloromercuriphenylsulphonate was exposed to air no further sedimenting components were formed (Fig. 1).

Treatment with N-ethyl maleimide (10^{-3} M) for about 45 min. caused about 45 per cent inhibition of the lactate–ferricyanide reductase activity of cytochrome b_2 and a corresponding appearance of flavin fluorescence.

It appears, therefore, that exposure of cytochrome b_2 to oxygen may cause a rapid dissociation of some of the riboflavin phosphate, accompanied by aggregation of the protein. The dissociation of flavin and the prevention of aggregation by p-chloromercuriphenylsulphonate provide further evidence that the flavin is bound to the protein by sulphydryl group(s). The aggregation caused by air is attributed to the formation of intermolecular disulphide bonds, with a concomitant displacement of the flavin group. Although it seems highly likely that the intermolecular disulphide bridge is formed by oxidation of sulphydryl groups previously masked by riboflavin phosphate, this has not yet been established with certainty. There are approximately 18 half-cystine residues/mole of hæm in cytochrome b_2 (ref. 8).

Other workers have recently shown that the flavin adenine dinucleotide prosthetic group of D-amino-acid oxidase is bound by its flavin to the protein via a sulphydryl group[9,10]. In this case, however, there is also bonding between the protein and the adenine portion of flavin adenine dinucleotide. As compared with the few known flavoproteins having riboflavin phosphate as the prosthetic group, many of the flavoproteins containing flavin adenine dinucleotide are rather stable and resist dissociation of their flavin prosthetic group.

Since the apoprotein of D-amino-acid oxidase is fairly readily reactivated by flavin adenine dinucleotide, it is possible that the oxidation of unmasked sulphydryl groups to disulphide bonds is prevented by steric effects. Theorell[11] suggested that the riboflavin phosphate of old yellow enzyme of yeast was bound to the apoprotein by a hydrogen bond involving the isoalloxazine nucleus and a tyrosine residue of the protein. In this enzyme no sulphydryl group was detected. The requirement of a p-chloromercuribenzoate-sensitive thiol group for enzymic activity has been reported for a number of other flavoproteins[12,13].

LETTERS TO THE EDITORS

COSMOLOGY

The Interpretation of Cosmology

We have to postulate that every part of the universe interacts, directly or indirectly, with every other part. We are probably justified in assuming that all fundamental interactions are propagated with the speed of light. It follows that we see all other parts of the universe in the state in which they influence our own part of the universe now. Therefore we can in principle predict the immediate future behaviour of our own part of the universe.

The situation is quite different as regards any remote part P of the universe. We see no other part of the universe in the state in which it influences P. For example, if P is 10^9 light-years away and Q is a part of the universe 10^9 light years away in the opposite direction, then, if the universe is static, whatever influence Q has on P when we observe P depends upon the state of Q at a time 2×10^9 years before Q was in the state in which we observe Q. But the universe is not static, and so we know nothing from observation about the state of Q when Q influenced the state of P in which we observe P.

Were the universe a finite system, we could overcome the situation by continuing our observations for a sufficiently long, but finite, time and then making predictions for still later times. But we almost certainly have to regard the universe as unbounded. Therefore, even in principle, we cannot predict the behaviour of a remote part of the universe with as much assurance as we can predict that of a nearer part.

This reveals a feature that ought to be built into any satisfactory theory of cosmology. Moreover, it agrees completely with our intuitive notion that we should be able to make predictions about sufficiently small parts of the universe, sufficiently near in space and time, but that we should be able to do no more than describe when we come to deal with regions so large that the uniqueness of the universe becomes relevant.

It thus appears that there is an uncertainty in cosmology, which may be said to be occasioned by the fact that the speed of light is not infinite, that is complementary to the uncertainty in atomic physics, which may be said to be occasioned by the fact that the quantum of action is not zero.

This feature is not in fact incorporated in current cosmological theory. But, if what has been said is significant, we seem to be driven to infer that the unavoidable uncertainty in any prediction about the part of the universe out to any particular distance is measured by $1 + z$, where z is the cosmological red-shift at that distance. (The usual definition is $1 + z$ = wave-length observed ÷ wave-length emitted.)

Now the difference between the predictions of evolutionary and steady-static cosmologies is only in factors $(1 + z)$, as was recently shown explicitly by P. S. Florides and me[1]. Thus an immediate consequence of the present view is that the difference between these theories loses any meaning. In fact, all problems concerning the creation of matter as hitherto formulated appear to lose significance. It is suggested that this is basically why all efforts to reach a decision between the two types of theory by observational tests have failed.

Following these ideas, the 'cosmological principle' would now assert that the universe as seen by a distant observer is like the universe as seen by us only to within a factor of uncertainty $(1 + z)$ in the description. Thus we should be asserting almost nothing about what the universe is like at great distances (in space or time). This provides a view of cosmology that essentially leaves room for endless observational surprises. It seems more satisfactory than the recent trend towards a belief that the nature of the 'whole' universe has already been discovered.

ASTROPHYSICS

Solar Limb Surges accompanied by X-Ray Emission

Sudden enhancements of atmospherics are recorded during solar flares[1]. The extra ionization of the lower D region at these times is brought about by X-rays emitted from the disturbed solar region[2].

The simultaneous observations in H_α line and records of atmospherics (27 kc./s.) carried out at our observatory indicate a pronounced coincidence in time

Table 1

	Limb surge		Sudden enhancements of atmospherics (disturbance of D region)

of sudden enhancements of atmospherics with surge appearances[3]. Projected on the disk the surges are, as a rule, connected with some bright H_α event in the underlying chromosphere (flare, plage brightening). We selected from our observations only those limb surges the disturbed underlying chromospheric region of which was behind the limb on the back side of the Sun. From these limb surges we excluded those coinciding in time with some other H_α event on the Sun, in order to eliminate ambiguity. The list of the remaining limb surges accompanied by sudden enhancements of atmospherics and eventually by radio radiation is given in Table 1.

We conclude that the sudden enhancements of atmospherics accompanying the limb surges could be interpreted as X-ray radiation emitted by the adjacent region of the solar corona.

Rocket and Satellite Observations of the Solar Ultra-violet Spectrum

THE Lyman lines of hydrogen, as well as the corresponding lines of He I and He II, are of interest both as tools for analysing the solar atmosphere and as energy sources for the terrestrial ionosphere. So far, interest in these lines has centred mainly around the Lyman-α lines because of their greater strength.

Rocket and satellite programmes are under way for the continuous monitoring of the energy-flux and the accurate determination of the profiles of the Lyman-α lines. It is the purpose of this communication to direct attention to the unusual importance of parallel observations of the Lyman-β lines.

In the Doppler core of a line, the source-function, S, may be written in the form:

$$S = \frac{\gamma B}{\rho + \beta}$$

where B is the Planck-function, γ is slowly dependent upon electron density and kinetic temperature, and β and ρ are dependent upon the opacity as well as electron density and temperature. Our interest here lies in the evaluation of ρ, which represents the net rate of radiative transitions in the line normalized to unity in the case of no absorptions.

The evaluation of ρ requires integration of the equation of radiative transfer[1]. At $\tau \approx 1$, $\rho \gg \beta$. However, the explicit value of ρ depends markedly on the temperature gradient in the regions of the atmosphere for which $1 \lesssim \tau \lesssim (3\beta)^{-1/2}$. In the case of the Lyman-α lines, $(3\beta)^{-1/2} \gtrsim 10^2$ for H and He I and $\gtrsim 10^4$ for He II. On the other hand, for the Lyman-β lines $(3\beta)^{-1/2} \approx 2$. Thus, the intensities near the centres of the Lyman-α lines are influenced by the temperature structure throughout a large range in τ, whereas the intensities near the centres of the Lyman-β lines are determined primarily by the 'local' conditions at $\tau = 1$ in the solar atmosphere. For this reason, data for the Lyman-β lines present a much stronger supplement to Lyman-α data than if the two lines behaved in the same way, and the analysis of one line will be greatly facilitated if data for the other line are available.

A more detailed report of this work will appear elsewhere.

PHYSICS

Silver-activated Nitrocellulose as Recording Material for X-Ray Microscopy

ELECTRON optical enlargement of X-ray absorption micrographs has been discussed by Pattee[1] and Asunmaa[2]. A contact micrograph is recorded on a thin layer of material sensitive to X-rays in which the absorbed radiation promotes physical or chemical changes that modify the areal electron density. For example, there may be a decomposition resulting in soluble products which are afterwards removed. A relief image with details of submicroscopic scale then shows an electron optical contrast. For electron optical enlargement of an X-ray absorption micrograph (instead of a replica of it) certain conditions are necessary, particularly if the electron micrograph is to reproduce the quantitative properties of the X-ray absorption images[2].

Most film materials thin enough for recording X-ray images with good resolution and suitable for use in transmission electron microscopy as specimens with so-called characteristic thickness are radiographically slow. Recording speed can be increased by additional absorbents and by selection of radiation-induced reactions with considerable quantum yield.

Nitrocellulose activated by a radiation trap (inorganic crystals or organic degradative dyes in alkaline or acidic media) meets the requirements for recording speed and has been found to possess other suitable properties such as reduced sensitivity after development of the X-ray record. The irradiated areas of the film are efficiently destroyed, because of the sensitivity of the β-glucosidic bond of cellulose to ultra-violet and X-ray energy, and because of the autocatalytic degradation of the cellulose nitrate, which is accelerated by radiation, to form products of low molecular weight through depolymerization, denitration and hydrolytic degradation. A subsequent fractionated extraction removes the main part of the degradation products from the polymer matrix and the small molecules diffuse readily in the solvated solid. X-ray absorption by the polymer is favoured by the uniform distribution of compounds sensitive to radiation, namely, tetrazolium chloride in previous experiments[2], or submicroscopic silver halide crystals in a so-called Goldberg emulsion, known for its fine grain in photographic processes[4] and now utilized for its nitrocellulose component.

Goldberg emulsion was produced by mixing lithium chloride and silver nitrate solutions to form silver chloride dispersed in an acidic medium of 2 per cent nitrocellulose (10·8–12·2 per cent nitrogen) in a mixture of ethanol and ether. Uniform films, about 1000 Å. thick, were cast and irradiated on a glass surface under atmospheric conditions as well as in high vacuum through test objects in direct contact with the recording film. The X-rays originated in a 10–30-μ focal spot 2 mm. from the recording material in a microfocus X-ray tube or from an electron beam ('Hitachi *HU*-10') using its diffraction stage as target holder and 20 kV. acceleration. Exposures ranging from 10 min. to 1 hr. were used, dependent on the spectrum and intensity of the X-rays. Mainly aluminium K and nickel L radiation were used.

Radiolytically reduced metallic silver gave a direct visible image, but this optical contrast does not correspond to differences in electron scattering. The electron optical contrast was produced by treatment of the film with a 2 per cent solution of sodium cyanide in 20 per cent methanol. The silver and the silver salts were removed as water-soluble cyanide complex compounds. Lithium chloride and the main fraction of the degradation products were dissolved away through the methanol-swollen film. The remaining solvent-resistant polymer produced a relief image with differences in mass thicknesses. This relief film was less sensitive to subsequent electron bombardment than the corresponding image recorded on pure nitrocellulose.

The X-ray records were magnified in an electron microscope using a low-intensity 50-kV. or a 30-kV. electron beam ('Hitachi *HU*-10'). The rendering of the edges of the X-ray records of metallic objects (bars of a 1,500/in. silver grid) and of silica diatoms was fairly sharp in the electron micrographs (Figs. 1 and 2), showing that the X-ray effect was well confined on film areas receiving radiation. An energy transfer along a polymer chain to its most sensitive links thus did not limit the resolution. Gradations of photographic density in Fig. 2 correspond to graduated X-ray dosage; this makes X-ray absorptiometry possible, if suitable calibration can be employed. Fig. 3 shows an electron optical enlargement of an X-ray absorption micrograph of one diatom hole. The submicroscopic net bars, respectively about 600 Å. and 300 Å. wide (as illustrated in Fig. 4), are resolved, so a resolution better than 600 Å. is obviously attained. These dimensions are still more than one order of magnitude larger than the electron optical resolving power applied, and the net bar images therefore are suitable for the study of scattering contrasts (*Streuabsorption*[5]).

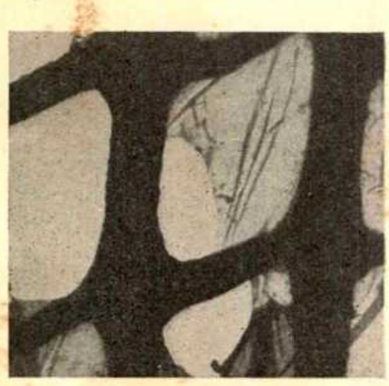

Fig. 1. Electron optical enlargement of an X-ray absorption micrograph of a 1,500/in. silver grid. Over-exposed to X-rays, supporting film broken

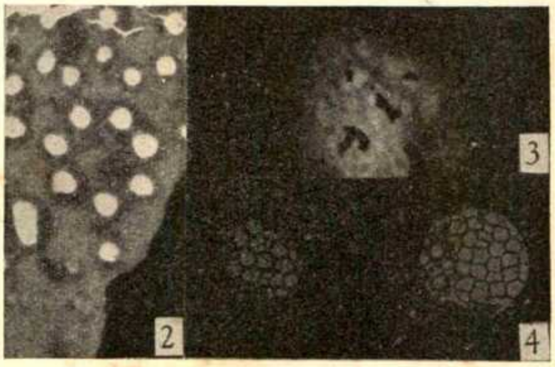

Fig. 2. Electron optical enlargement (× 1,600) of an X-ray absorption micrograph of a part of a diatom. Note the graduated X-ray effect

Fig. 3. Electron optical enlargement (× 19,000) of an X-ray absorption micrograph of a submicroscopic net in the hole of a diatom

Fig. 4. Electron micrograph (× 6,400) of submicroscopic net structures in diatom holes

The acceleration of the irradiation-induced reaction by the inorganic components is probably produced by photoelectrons and by re-radiation when silver ions trap electrons which have been liberated by X-ray absorption. Since oxidation is negligible, the method can be applied to irradiation in air as well as in high vacuum. The reduced sensitivity to radiation of the final record is probably produced by an initial overall polymerization during the induction period of the main irradiation reaction. There has been no attempt to measure the submicroscopic distortion which 'development' and irradiation processes may cause in the dimensions of the record.

I thank Prof. P. Kirkpatrick and Dr. P. V. Laakso for their interest.

Intrinsic Recombination Radiation in Diamond

DETAILED observations have been recently reported of radiation emission in germanium and silicon, which has been interpreted in terms of exciton recombination with emission and absorption of phonons[1,2]. In view of the similarities between these substances and diamond, it is of interest to look for analogous emission in the latter.

The visible luminescence spectrum of diamond consists mainly of a broad blue band, having its maximum at about 4400 Å. (2·8 eV.) and a complex, green–red system. The distribution of energy between these two regions depends markedly on the specimen, and the emission is thought to be connected with vacancies and substitutional impurities. Recent ultra-

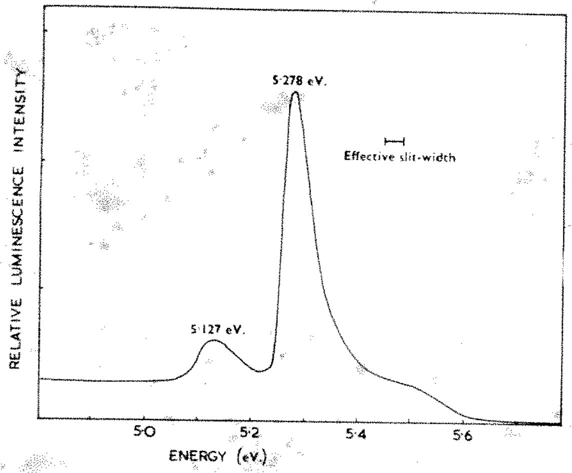

Fig. 1. Spectrum of intrinsic recombination radiation from diamond

violet absorption measurements[3] indicate that the threshold energy for indirect transitions between the valence and conduction bands is approximately 5·4 eV. at room temperature. This is some five times greater than the energy-gap for silicon, and it is to be expected that intrinsic radiative recombination will be an improbable process when compared with recombination via the centres mentioned above[4].

We have observed ultra-violet emission from a strongly blue-luminescent diamond which showed weak, ultra-violet transmission up to a quantum energy of 5·50 eV. The luminescence was stimulated by direct carrier injection, using an alternating potential of 150 volts at 50 c./s. applied between electrodes of colloidal graphite painted on to opposite faces of the crystal, which were 1·5 mm. apart. The diamond was mounted directly over the entrance slit of a Hilger medium quartz spectrometer. The spectrum was detected by a specially selected, low-noise, quartz-window photo-multiplier (*EMI*. 6256*B*) and recorded on a Brown strip-chart recorder.

The radiation emitted has a maximum energy of about 5·6 eV., and intensity maxima occur at energies of 5·278 ± 0·002 eV. and 5·125 ± 0·005 eV. The peak intensity at 5·278 eV. is of the order of 0·1 per cent of the intensity at the maximum of the blue band at 4400 Å. In view of the large effective slit-width employed, extrapolation of the low-energy sides of the intensity maxima to the energy axis is uncertain. The energies obtained in this way should be those associated with transitions involving recombination of excitons having zero velocity, with phonon emission. Analysis of the shape of the 5·278-eV. peak, using the method of Haynes *et al.*[1], indicates that the recombination probability for the excitons is proportional to $1/v^n$, where v is the exciton velocity and n lies between 1 and 2.

The visible luminescence appeared to be concentrated in a small region of diameter approximately 100μ, situated close to the crystal surface on the side facing the spectrometer slit, and it is presumed that the ultra-violet emission also originated at this point. Unfortunately, no other diamond was available which showed intense electroluminescence at voltages sufficiently low for measurements to be carried out at atmospheric pressure without interference from air discharges. However, it is hoped to carry out further investigations in the near future, using an electron beam to excite the free carriers. Attempts to assign phonon energies to the transitions will be delayed until these measurements and more unambiguous ultra-violet absorption data are available.

Detection of Negative Ions formed by Charge Transfer

We have reported recently the results of a series of measurements of the electron loss cross-section for hydrogen atoms of 5–40 keV. energy in various gases[1,2]. The method employed is capable of some precision, and the cross-sections obtained are accurate, we believe, to within 2–3 per cent. As a result we have been able to determine that in hydrogen and in carbon monoxide the cross-section does not vary smoothly with energy, but has a number of large fluctuations. In the carbon monoxide cross-section, for example, there are nine maxima in the region 8–40 keV. The magnitude of the oscillations is of the order of 10^{-16} cm.^{2} in a total cross-section of the order of 1–5 × 10^{-16} cm.^{2}.

On the other hand, the cross-section shows no such variation for argon. Thus it seems likely that the sudden increases which occur in the cross-section for electron loss are associated with a process which leaves the electron attached to the target molecule or a fragment of it after the collision rather than in a free state. The lack of resonances in argon indicates that this is the cause of the increases rather than some other inelastic process such as excitation of the target molecule, which might also reduce the chance that the electron emerge from the collision still attached to the incident proton.

Furthermore, we have constructed a model of a collision process which results in the formation of a negative ion of the target gas, and seems to give rather impressive numerical results. According to this model, an extra electron-loss channel is opened leading to the formation of negative ions when the target molecule has a positive electron affinity. As a hydrogen atom approaches a molecule the electron to be captured first makes a transition to the continuum. This leaves it travelling toward the target molecule and somewhat faster than the proton with a velocity $V_H + \Delta V$, where V_H is the initial velocity of the hydrogen atom in the laboratory. The kinetic energy of the electron in the laboratory is then $m_e(V_H + \Delta V)^2/2$, and it behaves in the rest of the collision just as a free electron. There is a high probability that it can be captured if this energy is sufficient to produce a negative ion state of the target molecule in accordance with the operation of the Franck–Condon principle. The cross-section should, however, be very much larger than the analogous free-electron process because of the proximity of the proton. Energy and momentum balance can readily be achieved.

Table 1. THRESHOLDS OF ELECTRON-LOSS CROSS-SECTION PEAKS AND CORRESPONDING ELECTRON-ENERGY COMPARED WITH EXPECTED APPEARANCE POTENTIALS FOR NEGATIVE IONS

Hydrogen energy (keV.)	Electron energy (eV.)	Appearance potentials (eV.)	
8·10	6·59		
12·55	9·71	9·66	$C(^3P) + O^-$
14·45	11·03	10 92	$C(^1D) + O^-$
16·6	12·5	12 84	$C(^1S) + O^-$
23·50	17·15	17·11	$C^* + O^-$
28·77	20 65	20·93	$C^+(^3P) + O^- + e$
32 4	23·30	23 40 or 23·63	$C^- + O^+ + e$
35·40	25 25		
36·9	26 12	26·26	$C^+(^4P) + O^- + e$

It was found that if ΔV was assumed to be a linearly increasing function of V_H—and the same function for hydrogen, carbon monoxide and water impurities in the hydrogen experiment—almost all the cross-section peaks could be associated with the various possible negative ion states of hydrogen, water and carbon monoxide. Table 1, reproduced here from a previous communication[2] for the sake of completeness, shows the predicted appearance potentials of various negative ion states of carbon monoxide, and the observed thresholds in terms of the energy of the hydrogen atom and the associated electron-energy computed on the basis of our model. A particularly notable feature of Table 1 is that the peak in the cross-section near 10 keV. must correspond to the formation of the bound molecular ion CO^- since the electron-energy is less than 9·66 eV., the dissociation energy of CO^-. It is to be remarked also that only one peak appears to correspond to the formation of C^-, namely, that at an energy of the hydrogen atom of 33·82 keV.

We have constructed a simple mass-spectrometer designed to detect whatever ions are produced in a gas through which a fast atomic or ionic beam is passed. We have found that negative ions are in fact formed in certain gases by fast hydrogen atoms. These gases are hydrogen, carbon monoxide, water and oxygen. No negative ions could be detected in helium, argon or nitrogen. In hydrogen we have detected H^-; in carbon monoxide, C^-, O^- and CO^-; in water, H^- and O^-; and in oxygen, O^-. The cross-sections for the formation of negative ions appear to be very large, as we expected. In fact in CO we have found them to be of the order of 10^{-16} cm.^{2} at the maxima and to vary in the same way as the cross-section for electron-loss for the hydrogen atoms; that is, maxima and minima occur for the same hydrogen atom energies. The relative variation is much larger in the cross-section for formation of negative ion. There are, of course, other processes which contribute to the cross-section for electron-loss.

In Table 2 we present an analysis of the ions found at various atomic beam-energies. The relative rate of formation for the various species is obtained by an extrapolation to zero carbon monoxide pressure. At most energies it was found that a weakly bound CO^- was formed which inevitably broke up into C and O^- before reaching the magnet of the mass spectrometer. This species is denoted by the symbol $CO^- \rightarrow O^-$ in Table 2. On the other hand, as predicted, the predominant ion in the 12-keV. peak is a firmly bound CO^- ion. C^- is found at one energy only, namely, at 33·82 keV., again as predicted. The total cross-sections for formation of negative ions are given where they have been measured.

Table 2. NEGATIVE IONS FORMED BY THE PASSAGE OF HYDROGEN ATOMS THROUGH CARBON MONOXIDE AT VARIOUS ENERGIES

The relative rates of production of the various species and the cross-sections for formation of negative ions where they have been measured are also given

Hydrogen energy (keV.)	Ionic species		Cross-section (cm.^{2})
12.00	CO^- (98 per cent)	O^-	1 0 × 10^{-16}
13·07	O^-	$CO^- \rightarrow O^-$	
13 75	O^- (98 per cent)	$CO^- \rightarrow O^-$	1·1 × 10^{-16}
14·34	O^- (91 per cent)	CO^-	0·22 × 10^{-16}
16·29	O^- (90 per cent)	$CO^- \rightarrow O^-$	1 26 × 10^{-16}
17 42	O^- (82 per cent)	$CO^- \rightarrow O^-$	0 33 × 10^{-16}
30 71	$m_{\text{eff}} = 20$	$CO^- \rightarrow O^-$	
33 82	$m_{\text{eff.}} = 20$	$CO^- \rightarrow O^-, C^-$	

It appears that this process is by far the most effective yet found for formation of negative ions. It ought to play an important part in the upper atmosphere—particularly during auroræ—and in stellar atmospheres. It should be noticed that such processes as:

$$H + O \rightarrow O^- + H^+$$

would also appear to be possible because of the presence of the proton. Finally, the results of the ion analysis appear to confirm the validity of the model we have presented. The nature of the events leading to the formation of the loosely bound CO^- species remains, however, unknown.

GEOLOGY

West-Pacific Stratigraphic Correlation

THE development of reliable methods of world-wide stratigraphic correlation involves the gradual replacement of empirical and traditional 'index fossils' by zonal index species selected on the basis of carefully analysed factors concerning their evolution and distribution. This approach favours abundant fossils to which statistical methods of population study can be applied, such as Foraminifera; rapidly evolving lineages, such as larger Foraminifera; and widespread forms, relatively independent of facies, such as planktonic organisms. It also necessitates a major effort to clarify stratigraphic terminology and classification which is expected to be significantly advanced soon as a result of the work of the Commission on Stratigraphy of the International Geological Congress. The framework of the conventional stratigraphic subdivisions of geological time, dating back to the time when geological knowledge began to accumulate long ago in Europe, is found to lack precision and to suffer from other deficiencies when attempts are made to accommodate in it the results of precise stratigraphic correlation in previously unknown parts of the world. Patient co-operative work of stratigraphers and palæontologists in different continents is required in order to overcome the difficulties and misunderstandings resulting from an over-extension of weakly founded terms and concepts. As Gignoux[1] has stated, it is essential first to establish local stratigraphic sequences (on a rock stratigraphic and zonal biostratigraphic basis, I might now add) and to generalize them only cautiously.

"Much of the correlation of mid-Tertiary Indo-Pacific foraminiferal assemblages depends at present on the recognition of the *Globigerinatella insueta—Globigerinoides bispherícus* zone. Its significance for the Pacific region was first recognized by Todd *et al.*[2], who found it represented on Saipan. The subsequent publication of the geology of Saipan by Cloud *et al.*[3] now enables the stratigraphic relations of this fauna to be examined more closely[4]." In a recent contribution to a stratigraphic handbook[5] I mentioned briefly an alternative view of the relations of this zone fauna from the Mariana Islands which links the Tertiary of the West Pacific with that of the West Indies. It appears now that the original assumptions have led to confusion in the interpretation of important further discoveries. A brief discussion of the problem and its solution is therefore here presented. The *G. insueta*-fauna was found in tuffs (later named the Fina-Sisu formation) which were stated to dip beneath sub-horizontal limestones (Tagpochau Limestone) that contain larger Foraminifera considered to be of Tertiary *e* (early Miocene) age. The fauna found in the vicinity of the tuff outcrops, as quoted in the original paper by Todd *et al.* and later described by Cole[6], does not contain restricted *e*-stage species. Only *Cycloclypeus eidae* Tan, "*Eorupertia semiornata* (Howchin)" (not figured from this locality), *Lepidocyclina sumatrensis* (Brady), *L. verbeeki* Newton and Holland, *Miogypsina thecideaeformis* Rutten, *Gypsina mariannensis* Hanzawa and *Marginopora vertebralis* (Quoy and Gaimard) occur at the relevant localities. This is definitely not an *e*-stage but an *f*-stage assemblage, in terms of the letter-classification of the Indonesian Tertiary. Older faunas were found elsewhere in the Tagpochau Limestone, and for this reason Cole placed the entire formation in the *e*-stage which he considered as Lower Miocene. The tuffs representing the zone of *Globigerinatella insueta* were accordingly placed in the Oligocene. This dating agreed with the then accepted correlation of this unit in the zonal sequence of the West Indies, but disagreed with subsequent revisions of the dating of the Tertiary of the West Indies by Eames, Drooger and others, according to whom the *insueta*-zone is either upper Aquitanian[7] or upper Vindobonian. This disagreement disappears if the Fina-Sisu tuffs in the southern part of Saipan are considered, as they should be on the evidence of published data, as overlain not by the basal part of the Tagpochau Limestone (this was assumed implicitly by Todd *et al.*) but by its highest portion which is to be placed in the *f*-stage. Interbedding of tuff and limestone is an alternative which does not appear to be inconsistent with the detailed map[3].

A close association of the planktonic Foraminifera of the *G. bispherica* zone with *f*-stage larger Foraminifera has just been described by Cole, Todd and Johnson[8] from Yap in the Caroline Islands. The previous assignment of these two groups of fossils to different zones, stages and even series on Saipan made it necessary for the authors to consider carefully possible alternatives, but these did not include a revision of the field relations, and their concluding statement (p. 91) reads as follows: "These rejected possibilities leave us with scarcely anything more than the conclusion that we cannot explain the conflicting evidence of age from the larger and smaller Foraminifera on Yap". Actually, the evidence from Saipan as re-interpreted here, together with new data from Australia and old records from Borneo[9], indicate that the distinctive benthonic larger Foraminifera characterizing the *f*-stage and the planktonic smaller Foraminifera of the *G. bisphericus* zone (= upper *Globigerinatella insueta* zone) are closely associated throughout this region. They also indicate the post-Aquitanian age of these assemblages[4]. A discussion of the discrepancy between this dating and the placing of the same zone in the Aquitanian[7] must await publication of fuller details.

GEOCHEMISTRY

Exposure Ages for Iron Meteorites

THE rare gases in iron meteorites induced by cosmic rays can be used to obtain estimates of the exposure ages of the meteorites[1–3]. The rare-gas nuclides are formed by the nuclear reactions induced by high-energy cosmic-ray particles at a presumably constant rate in time and space. The rate is, however, dependent on the depth at which the sample being investigated is below the surface of the meteorite in its flight through space. This depth is dependent on the absorption of the cosmic-ray particles by the meteorite.

In general, in order to estimate an exposure age, one needs a rate of production of a given nuclide and its total content in the meteorite. The activity-level of a radionuclide with a half-life short compared to the exposure age (usually 100–1,000 × 10^6 years) furnishes a measure of the rate of production; while modern mass-spectrometric techniques make possible the measurement of the rare-gas content of meteorites using of the order of 0·1 gm. per sample. However, the present methods being used for detection of radioactive products require of the order of 100 gm. per sample. As a result there are considerably more rare-gas measurements than radioactivity measurements. Recently such rare-gas measurements have been used to estimate exposure ages[1] by assuming all meteorite specimens are in the same cosmic flux. That is, it is assumed that the depth of a sample in the original body in space is never sufficiently large to cause a great variation in the production-rate of cosmic rays. While there is some evidence that this is the case for stone meteorites, it is certainly not the case for the iron meteorites, and any estimate based on a constant production-rate can, in a given case, be in error by more than an order of magnitude. It would clearly be desirable to have a method of estimating the production-rate from the rare-gas contents alone. Helium is formed with good yield by low-energy reactions while a product such as neon or argon is only found by relatively high-energy interactions. For this reason a ratio such as helium-3/argon-38, for example, is dependent on the ratio of high- to low-energy particles producing the interactions. In turn, this ratio is dependent on the depth below the surface. With increasing depth, relatively more low-energy secondaries are formed. In this way a ratio such as helium-3/argon-38 will furnish a measure of the depth.

There is a complication; if the meteorite should contain calcium, the argon-38 would also be produced in good yield by low-energy secondaries. However, one has available in addition to this ratio the ratio helium-3/neon-21 and helium-3/helium-4, both of which should show a similar dependence on the depth below the surface. Again, each of these ratios can be affected by the presence of an impurity. The presence of magnesium will alter neon-21 production markedly, while the presence of lithium or uranium will alter the ratio helium-3/helium-4. If the ratios helium-3/helium-4, helium-3/argon-38 and neon-21/argon-38 are used to derive a scale of depth, then it should be possible to pick out ratios that are anomalous.

It is thus possible to establish a scale of the production-rate of a given nuclide as a function of a rare-gas ratio. For example, the production-rate of helium-3 can be estimated from the ratios helium-3/argon-38 and the measurements of argon-39 and chlorine-36[4-6] for meteorites, the rare-gas contents of which have been determined on adjacent pieces, that is, at the same depth. The relations involved are:

(1) Production-rate of helium-3 = production-rate of chlorine-36 : $(^3\text{He}/^{38}\text{Ar})\dfrac{\sigma(^{38}\text{Ar})}{\sigma(^{36}\text{Cl})}$

(2) Production-rate of helium-3 = production-rate of argon-39 : $(^3\text{He}/^{38}\text{Ar})\dfrac{\sigma(^{38}\text{Ar})}{\sigma(^{39}\text{Ar})}$

where $(^3\text{He}/^{38}\text{Ar})$ represents the ratio of the rare-gas content of the meteorites. The ratios of cross-sections are obtained from the bombardment by high-energy protons of iron (see ref. 7, also Fisher and Schaeffer, unpublished work). These cross-sections are not very sensitive to the energy and so should be practically independent of the depth of the sample in the meteorite.

When the results in the literature are treated in this way, one can obtain the plot shown in Fig. 1. While the data show the usual spread when accumulating results from a number of independent laboratories, there is none the less a definite change in the production-rate with the ratio helium-3/argon-38. It should be possible to use this figure to interpret some of the results on the rare-gas contents of iron meteorites.

Table 1. METEORITES LISTED IN ORDER OF INCREASING DEPTH

Meteorite	Helium-3 $\times 10^{-8}$ (c.c. N.T.P./gm.)	Helium-3 / Helium-4	Helium-3 / Argon-38	Neon-21 / Argon-38
Washington Co.	193 ± 20	0·067	26	0·28
Tucson	13 ± 1	0·09	25	1·5
Forsyth Co.	48 ± 6	0·32	23	0·28

Santa Rosa	47 ± 5	0·26	21	0·19
Santa Catherina	57 ± 6	0·25	22	0·19
Tombigbee River	4·7 ± 1	0 14	7·4	0·12

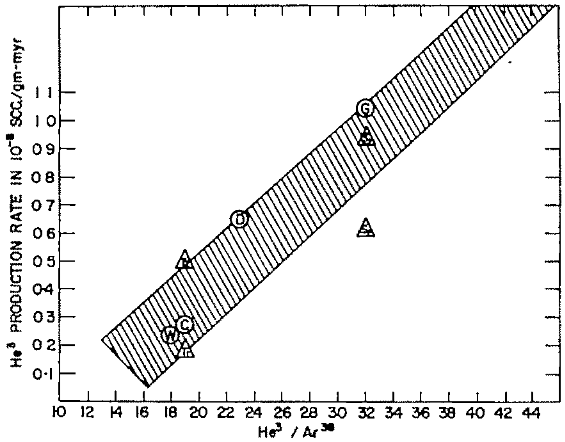

Fig. 1. Production-rate of helium-3 plotted against ratio of helium-3/argon-38. The circles are calculated from chlorine-36 data, the triangles from argon-39 data. *G*, Casas Grandes (ref. 5); S_1, Sikhote-Alin (ref. 5); S_2, Sikhote-Alin (ref. 4); *D*, Canon Diablo (ref. 5); *C*, Carbo (ref. 5); T_1, Treysa (ref. 10), T_2, Treysa (ref. 4); *W*, Williamstown (ref. 5)

Recently the rare-gas contents of several meteorites have been measured[8]. These are listed in Table 1 in order of increasing depth as determined from the ratios helium-3/helium-4, helium-3/argon-38 and neon-21/argon-38.

It can be seen that not all the ratios vary uniformly, and it is suggested that the presence of small amounts of impurities may be influencing the ratios. For example, the low values of the ratios helium-3/helium-4 in the Washington County and Tucson meteorites are probably due to the presence of radiogenic helium from uranium or primordial helium[8,9]; while the high ratio neon-21/argon-38 in Tucson is probably due to the production of neon-21 from magnesium and silicon, which are known to be present to the extent of several per cent in this meteorite.

Table 2. COSMIC-RAY EXPOSURE AGES

Meteorite	Age (million years)	Meteorite	Age (million years)

† From the data of Gentner and Zähringer (see ref. 12).
‡ From the data of Kistner (see ref. 6).

By the use of Fig. 1, the ratio helium-3/argon-38 and the helium-3 content, it is now possible to

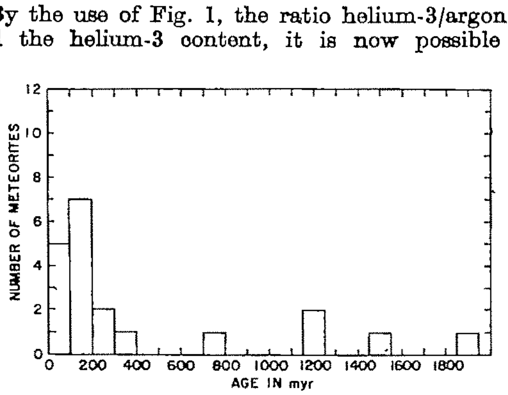

Fig. 2. Cosmic ray exposure ages of the iron meteorites

estimate ages for all the meteorites in Table 1, as well as a number which have been reported in the literature. These are tabulated in Table 2.

The data have been arranged in a histogram in Fig. 2, from which it can be seen that the exposure ages show a variation extending to nearly two thousand million years, with a most probable value near 100–200 million years. This can be interpreted as characteristic of a continual breaking-up process of bodies in space, leading to freshly exposed surfaces.

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

CHEMISTRY

Effect of Solvent Polarizability on the Ultra-Violet Spectral Shifts of Aromatic Compounds

IT is generally recognized that non-polar solvents cause a long wave-length shift of the optical spectral maxima of absorbing solutes, and that this shift tends to increase with the polarizability of the solvent. Bayliss[1] has proposed that:

$$\Delta\nu(\text{cm.}^{-1}) = \frac{3e^2}{8\pi^2c^2m} \cdot \frac{f}{\nu a^3} \cdot \frac{n^2-1}{2n^2+2} \qquad (1)$$

where $\Delta\nu$ is the long wave-length shift, compared to the dilute vapour spectral position, f is the oscillator strength (that is, the number of 'classical' absorbing electrons), a is the radius of the absorbing molecule, n is the refractive index of the solvent, and the other symbols have their usual significance. Longuet-Higgins and Pople[2] have proposed the relationship:

$$\text{red shift} = \frac{1}{6}\,\alpha_B z\bar{R}^{-6}\left(\frac{1}{4}\,E\alpha_A + M\right) \qquad (2)$$

where the shift is expressed in energy (frequency × h); α_A and α_B are the molecular polarizabilities of the solute and solvent, respectively, and M and E are the dipole moment and energy of the transition. Each solute molecule is regarded as being surrounded by z solvent molecules at a mean distance $\bar{R}$. This relationship predicts that the long wave-length shift will be proportional to $(n^2-1)/(n^2+2)$. Both equations predict that $\Delta\nu(\text{cm.}^{-1})$ or $\Delta\lambda$ ($\Delta\lambda = \lambda_s - \lambda_0$, where the subscripts refer to solvent and vapour respectively; over the very short wave-length range to be considered here, $\Delta\lambda = \Delta\nu\lambda^2$ to a high degree of approximation) will approach zero only in the vapour state, and that in any solvent a substantial shift should be observed. Similar but more elaborate theoretical treatments have been given by Ooshika[3] and McRae[4].

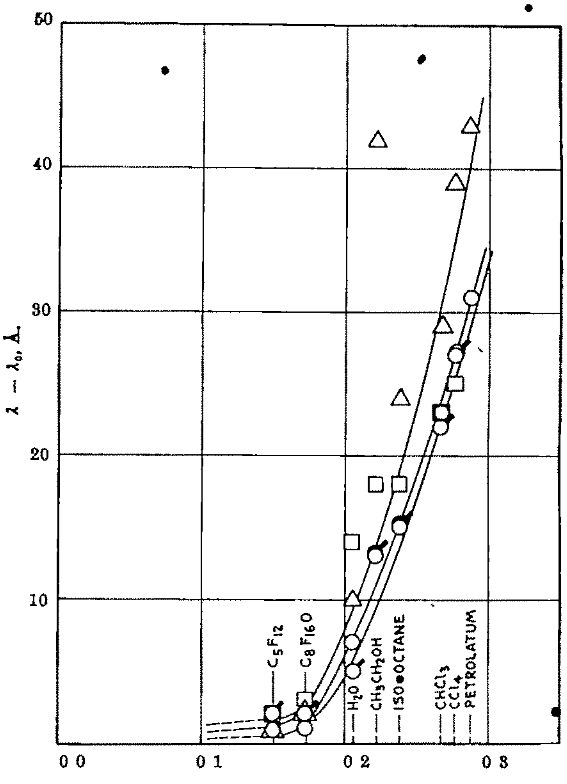

Fig. 1. The long wave-length shift $\lambda_s - \lambda_0$ (Å.), compared to vapour, of the ultra-violet spectral maxima of four aromatic compounds in solvents of refractive index n, plotted as a function of $(n^2-1)/(n^2+2)$; ○, benzene; △, phenol; ♂, fluorobenzene; □, benzotrifluoride

There appear to be very few data on ultra-violet and visible spectral shifts in non-polar solvents which permit a test of these equations. Lauer and Oda[5] found the shift of the benzene spectrum tended to increase with solvent refractive index, but the scatter of their data is too large to permit a test of any definite relationship. In addition, the reported vapour maxima positions are in error. Shepard[6] presented data for a merocyanine dye in four solvents. A linear plot of $\Delta\lambda$ vs. n appeared to pass through the origin; but the extrapolation was rather long. A recalculation of these data by Bayliss[1] gave a plot of $\Delta\nu(\text{cm.}^{-1})$ vs. $(n^2-1)/(2n^2+1)$ which did not pass through the origin; a similar plot for solutions of bromine likewise did not pass through the origin. Phibbs[7] observed that solutions of atomic mercury in water and several organic solvents did not obey Bayliss's relationship. Ham[8] found that complexes of iodine with benzene, mesitylene, and hexamethylbenzene gave shifts which were linear in $(n^2-1)/(2n^2+1)$, and McRae[4] observed similar behaviour for phenol blue, but in both cases the vapour position is indeterminate.

In the course of an investigation of the ultra-violet spectra of proteins and protein models[9], we have had occasion to measure carefully the ultra-violet spectral shifts of benzene, phenol, fluorobenzene, and benzotrifluoride in solvents of varying polarity and polarizability. A particular feature of this study is the inclusion of two solvents of very low polarizability: a cyclic perfluoro-C_8 ether, $C_8F_{16}O$, manufactured by Minnesota Mining and Manufacturing Co. ($n_D^{25} = 1{\cdot}2775$), and perfluoropentane ($n_D^{25} = 1{\cdot}2390$). This enables the relationship of $\lambda_s - \lambda_0$ to n to be extended to considerably lower n than in previous studies. A Cary model 11 spectrophotometer was employed, 1-cm. cells with quartz windows being used for all solutions and a 5-cm. cell for vapour samples. The solution of benzene in petrolatum was measured using quartz plates with 0·015-cm. glass spacers; the refractive index of the petrolatum was 1·4858. The spectrum of a 5 per cent solution of benzene in the cyclic perfluoro-C_8 ether was recorded using a thin liquid film squeezed between quartz plates without spacers.

In Fig. 1 are shown the long wave-length shifts $\lambda_s - \lambda_0$ (in Å.) for benzene (0·0050 *M*, 2529 Å. vapour band), fluorobenzene (0·00115 *M*, 2644 Å. vapour band), phenol (0·00080 *M*, 2685 Å. vapour band[10]) and benzotrifluoride, (0·00390 *M*, 2645 Å. vapour band) in perfluoropentane, cyclic perfluoro-C_8 ether, water, ethanol, *iso*octane, chloroform, carbon tetrachloride and petrolatum, plotted vs. $(n^2 - 1)/(n^2 + 2)$. The refractive indices of the solvents and their positions along the abscissa of Fig. 1 increase in the order given. The spectral shifts for benzene lie on a nearly straight line which appears to extrapolate to an intercept of about 0·18 on the abscissa. Fluorobenzene shows very similar behaviour. Benzotrifluoride, which is quite polar ($\mu_D = 2{\cdot}63$ D.U.) but presumably does not form hydrogen bonds, shows somewhat larger shifts in water and ethanol, for which there appears to be no obvious explanation. Phenol shows a very large shift in ethanol (probably largely the result of hydrogen bonding, with the phenol acting predominantly as the hydrogen donor) but a 'normal' value in water[9] (where it may act equally as donor and acceptor). The slope of the line for phenol is somewhat greater than that for benzene and fluorobenzene, corresponding to its greater oscillator strength. All four give approximately straight lines for the solvents of higher refractive index, but the curve evidently bends sharply below about 0·15–0·17 on the abscissa, since it appears that it must pass through the origin. Therefore, none of the proposed relationships between $\lambda_s - \lambda_0$ (or $\Delta\nu$) and n is even approximately correct, at least for these systems.

The apparently nearly zero polarizability of the fluorocarbon solvents with respect to these aromatic solutes is of some interest, and is probably quite general. Although it is well recognized that the polarizability of fluorocarbons is relatively low, it is clear that it is far from zero. For example, the van der Waals forces between fluorocarbon molecules are large enough so that their boiling points do not differ greatly from those of the corresponding hydrocarbons[11]. The van der Waals forces between fluorocarbon and hydrocarbon molecules are apparently peculiarly low, as judged by their low mutual solubility[12]. The very small spectral shifts may be in part another aspect of this anomalous behaviour. The problem seems to be broader than this, however, for the observed shifts for all the other solvents lie close to the same nearly straight line, which does not have the slope or origin indicated by theory.

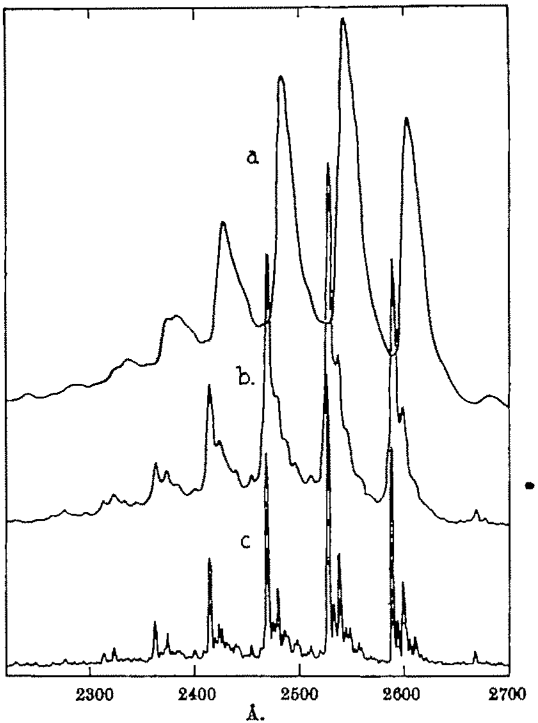

Fig. 2. The ultra-violet spectrum of benzene in *iso*octane (*a*), cyclic perfluoro-C_8 ether (*b*), and vapour (approximately 70 mm.) (*c*)

The fluorocarbon systems represent in an accentuated and striking form an anomaly which is to some degree shared by the other systems.

A possible explanation for these results is that in dilute solutions the solute molecules may exist in part in cavities or holes in the solvent, and that therefore the factor $\bar{R}$ in equation (2) may be larger than expected. Since the shift is predicted to be dependent on $\bar{R}^{-6}$, only a relatively small cavity would need to be postulated. The equilibrium distribution of solute between cavities and the 'true' solvent medium might be imagined to favour the 'true' solvent medium increasingly with increasing solvent polarizability. For fluorocarbons, the solute might then be thought of as being almost entirely in the cavities. We have found, however, that for a 5 per cent solution of benzene in cyclic perfluoro-C_8 ether the spectral maxima are unchanged in position compared to the 500-times more dilute solution represented in Fig. 1. It appears most unlikely that cavities could be provided for these many solute molecules.

In Fig. 2 are compared the spectra of benzene vapour (approximately 70 mm.) and of benzene solutions in cyclic perfluoro-C_8 ether and in *iso*octane. It is of interest experimentally and theoretically that, because of the small interaction between solute and solvent, the spectrum in the fluorocarbon solvent shows a marked increase in resolution over that observed for the hydrocarbon solution; many features of the vibrational fine-structure visible in the vapour spectrum are clearly seen. Fluorocarbon solvents may thus provide vapour spectral positions and considerable fine structure for relatively non-volatile substances for which it would be inconvenient or impossible to obtain a true vapour spectrum.

We wish to acknowledge the able experimental assistance of Mrs. Lucy Klos and Mr. Floyd Vincent.

We are also grateful to Dr. G. V. D. Tiers for several stimulating discussions.

Note added in proof. After this paper had been submitted, Dr. John Foss (University of Oregon) directed our attention to a paper by Sverdlova[13] in which similar data are presented for benzene and chlorobenzene. In general, these data agree with ours; but they are plotted in such a way as to obscure the disagreement with theoretical prediction.

Absorption Spectra of Diatomic Radicals containing Boron or Silicon

Various workers have used methods of time-resolved absorption spectroscopy to study the formation and decay of free radicals produced in pulsed electric discharges. These investigations have been confined to the use of a single parent substance which normally flows through the discharge tube at a rate such that the parent substance is not completely replenished before each discharge pulse. In this way the absorption spectra of OH (ref. 1), CN (ref. 2) and of several halides such as BBr, BCl, AlBr, AlCl, AlI and SiCl[3,4] have been observed. The main limitation in this work was low intensity of the background sources used, and a large number of exposures were needed to obtain an adequate record with both high dispersion and good time resolution. The use of a flash tube filled with an inert gas as background source greatly reduces the number of exposures needed to obtain an adequate record and this removes the difficulty of studying systems where the discharge tube has to be refilled after each exposure.

An apparatus of this type has been constructed, and has been used for studying the absorption spectra of free radicals which have not previously been detected in absorption and which would be expected to have appreciable concentrations at the temperatures reached when a pulse electric discharge is passed through a suitable gas mixture at low pressure. In typical experiments a 1–5 μF. condenser at 10 kV. is discharged between tungsten electrodes 25 cm. apart in a 5-cm. diameter glass tube containing the parent mixture at a few mm. mercury pressure. A 100 *J* argon-filled quartz capillary flash tube with a duration of 7 μsec. is used to photograph the absorption spectrum on a 3-metre grating spectrograph. The firing of this lamp is controlled by an electronic delay circuit which is initiated by light from the discharge. With the optical arrangement used, the amount of light reaching the spectrograph from the discharge is small enough by comparison with intensity of the spectroscopic flash to make the use of shuttering unnecessary at wave-lengths above 2800 Å.

To date experiments have been concentrated on systems containing boron or silicon. For the former, either boron trichloride or trimethyl borate has been used, either alone or mixed with oxygen, nitrogen or hydrogen. In these systems, the absorption spectra of BCl ($A^1\Pi - X^1\Sigma$), BH ($A^1\Pi - X^1\Sigma^+$), BN ($^3\Pi - {}^3\Pi$), BO ($A^2\Pi - X^2\Sigma^+$)[5] and the "boric acid fluctuation bands"[6] have been observed. Of these, the observation of the triplet but not the singlet bands of BN (ref. 7) in absorption is of particular interest, since they suggest strongly that BN has a $^3\Pi$ ground-state, whereas the iso-electronic species C_2 has recently been shown to have a $^1\Sigma^+$ ground-state with its configurationally excited $^3\Pi$ state only about 610 cm.$^{-1}$ higher[8]. This difference in behaviour can be attributed to the fact that ground-state B(^2P) and N(^4S) atoms can only give triplet and quintet states, whereas singlet, triplet and quintet states can arise from two normal carbon atoms (^3P). Attempts are being made to observe the gas-phase absorption spectrum of BeO which is iso-electronic with BN and C_2 with the view of determining the relative positions of its lowest singlet and triplet states.

Preliminary experiments with silicon tetrachloride either alone or mixed with hydrogen or nitrogen have yielded the absorption spectra of SiCl ($B^2\Sigma - X^2\Pi$), SiH ($A^2\Delta - X^2\Pi$) and SiN ($B^2\Sigma^+ - X^2\Sigma^+$)[5]. In addition to observing most of the $B^2\Sigma - X^2\Pi$ bands of SiCl listed by Jevons[9], the (2,1) and (3,1) bands have been identified. The identification of these bands and the strong appearance of the (2,0) and (3,0) bands in these experiments confirm Jevons's assignments, about which he expressed some doubt. Under conditions when the $^2\Delta - {}^2\Pi$ band of SiH was most intense, a weak, slightly diffuse system appeared in absorption between 3900 and 3750 Å. This spectrum has been tentatively identified as the $^2\Sigma^- - {}^3\Pi$ transition of SiH to be expected in this region by analogy with CH. An attempt is being made to obtain this spectrum with enough intensity to permit a rotational analysis. No band system of SiH corresponding to the 3143 Å. $^2\Sigma^+ - {}^2\Pi$ transition of CH has yet been detected.

It can be seen that this technique provides a relatively simple method of studying the absorption spectra of species likely to be present at high temperatures without the use of large quantities of material or of elaborate apparatus to produce the high temperatures. A detailed account of this work is being prepared for publication.

I wish to thank Prof. R. G. W. Norrish for helpful discussions and the Government Grants Committee of the Royal Society for a grant, part of which was applied to this work

Analysis of Anæsthetic Mixtures by Gas Chromatography

During anæsthesia, and in respiratory research, there is a need to analyse mixtures of permanent gases and organic vapours on a routine basis. Physical methods are being increasingly used for this type of work, but the equipment required tends to become complex when the analysis of several components is desired. Chromatographic analysis is discontinuous in nature, but, provided that this can be tolerated, the use of gas chromatography offers several advantages of which simplicity and versatility are the most important.

For the separation of oxygen and nitrogen we have employed a column 12 in. long and ¼ in. internal diameter packed with 52–60 *B.S.* mesh Linde *5A* molecular sieve at room temperature. Samples can be analysed at 30-sec. intervals.

Carbon dioxide and nitrous oxide are commonly encountered in respired anæsthetic mixtures since the majority of anæsthetics are based on nitrous oxide and oxygen. None of the common adsorbents, such as silica gel, alumina and charcoal, will give an adequate separation of these gases. However, we have found that a *G.L.C.* column 24 ft. long by ¼ in. internal diameter packed with 28·6 per cent of propylene carbonate on 52–60 *B.S.* mesh 'SIL-O-CEL' firebrick will separate these gases at room temperature. A mixture of oxygen, carbon dioxide and nitrous oxide can be analysed in about 2½ min. on such a column. By overlapping the samples the analysis may be repeated every 2 min. Recently we have found that dimethyl sulphoxide is an even better stationary liquid for this work. A 20-ft. by ¼-in. column containing 20 per cent of dimethyl sulphoxide on 52–60 mesh 'SIL-O-CEL' at 20° C. will separate a mixture of oxygen, nitrous oxide and carbon dioxide in 1 min.

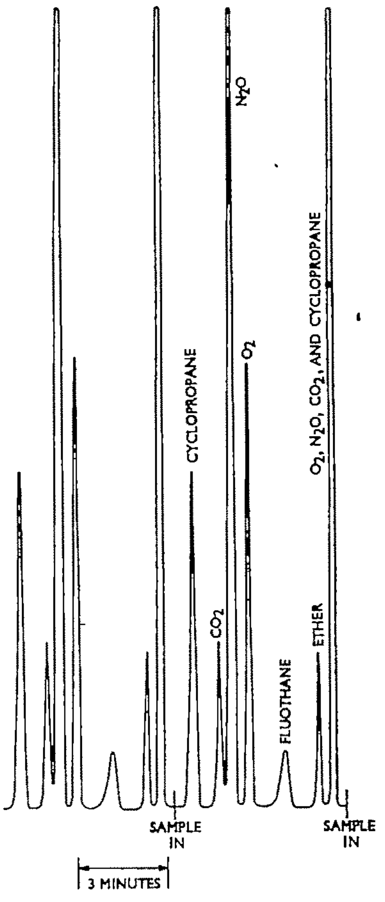

Fig. 1. Chromatogram of a respired anæsthetic mixture. Column 1, 20 ft. × ¼ in. 20 per cent dimethyl sulphoxide on 52–60 mesh 'SIL-O-CEL' at 20° C.; inlet pressure 280 mm. mercury. Column 2, 2 ft. × ¼ in. 15 per cent dinonyl phthalate on 52–60 mesh 'SIL-O-CEL' at 75° C.; inlet pressure 40 mm. mercury. Flow-rate, 30 ml./min. H_2 in both columns

When ether and fluothane are present, a 2-ft. by ¼-in. column containing 15 per cent of dinonyl phthalate on firebrick is used in parallel with the dimethyl sulphoxide column. Automatic valves[1] inject different-sized samples simultaneously into both columns. The dinonyl phthalate column is heated to 75° C., allowing the light gaseous components to pass through unresolved but retaining ether and fluothane long enough to give complete separation. The gases and vapours from the two columns pass through opposite channels of a thermistor thermal conductivity detector. The recorder in the bridge circuit is modified so that a negative signal actuates a reversing switch and consequently all the peaks on the recorder chart are in the same direction. Fig. 1 shows the separation of a respired anæsthetic mixture analysed in this way in approximately 4½ min.

We wish to thank Prof. R. F. Woomer, of the Royal College of Surgeons, and the Directors of "Shell" Research, Ltd., for their encouragement, and for permission to publish this communication. We also wish to thank colleagues at the Koninklijke/Shell-Laboratorium, Amsterdam, who suggested the use of dimethyl sulphoxide as a stationary liquid.

RADIATION CHEMISTRY

Radiative Life-time of the Pyrene Dimer and the Possible Role of Excited Dimers in Energy Transfer Processes

The absorption spectra of certain dye solutions exhibit a marked dependence on concentration over a range in which the corresponding fluorescence spectrum remains unchanged; this is attributed to absorption by non-fluorescent dimeric complexes at higher concentration which reduces the overall fluorescence yield of the solution[1]. The relative intensities of absorption by the dye in its monomeric and dimeric forms suggest that the radiative lifetimes of the corresponding excited species are both of the order of 10^{-8}–10^{-9} sec. (ref. 2).

On the other hand, Förster and Kasper[3] have observed that, whereas the absorption spectrum remains unchanged, the violet fluorescence of dilute solutions of pyrene is replaced by a blue emission at higher concentrations; in this case the excited dimer responsible for the blue fluorescence is formed

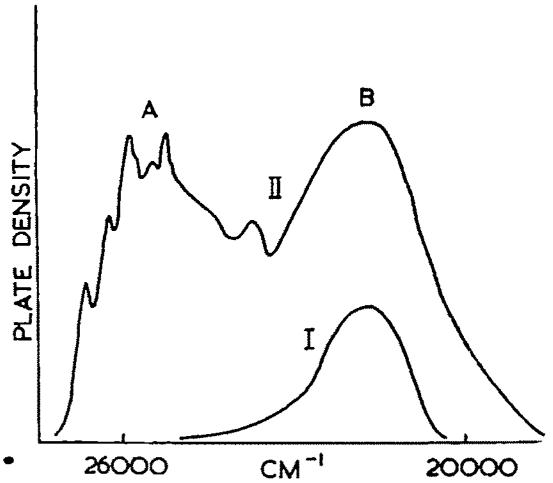

Fig 1. Spectrum of slow fluorescence of pyrene in solution photographed through phosphoroscope (I), and of total fluorescence (II) consisting of violet (monomer) and blue (dimer) bands *A* and *B*

collisionally from excited and unexcited pyrene molecules and, according to cryoscopic data, does not exist in the ground-state. Since measurement of the delay between absorption and emission observed in the vapours of pyrene and other aromatic hydrocarbons indicates that excited dimers formed in this way have a life-time of the order of 10^{-3} sec. even at temperatures of more than 200° C. (ref. 4), it would not be surprising if the radiative life-time of the pyrene dimer in solution were at least of the same order.

We thoroughly outgassed a $10^{-3} M$ solution of pyrene (Light's, white puriss.) in B.D.H. spectroscopically pure *cyclo*hexane in a 'Pyrex' cell and, using the flash photometric technique, observed a first-order emission component with a life-time of $1 \cdot 8 \pm 0 \cdot 2 \times 10^{-3}$ sec. To confirm that this component originates from the excited pyrene dimer, the fluorescence of the same solution in the same cell was excited by a 250-W. high-pressure mercury arc and photographed through a locally constructed phosphoroscope on a small Hilger quartz spectrograph. Fig. 1 shows a microdensitometer tracing of the exposed plate together with the total unsectored emission excited by the mercury 313 mμ line in the same solution.

A theoretical treatment[5] of the optical properties of dimers of this type shows that the radiative transition between excited and unexcited states is orbitally forbidden if the complex has a centre of symmetry, which accounts for the magnitude of the radiative life-time observed here. Consequently the corresponding absorption would be extremely difficult to detect even if the dimer exists to an appreciable extent in its ground-state, and the independence of the absorption spectrum of concentration is clearly no criterion for the non-existence of excited dimers at higher concentrations. On the contrary, an absorption spectrum independent of concentration indicates that any excited dimers formed are of the long-lived variety which will not be detected in emission or absorption if non-radiative processes leading to self-quenching compete successfully with fluorescence. In this case the evidence for their existence must be based on self-quenching itself[6], extremely efficient sensitization, a case of which has recently been suggested[7], or perhaps the appearance of unidentified bands observed in flash absorption spectroscopy of which a recently reported case may be an example[8]. Their reversible formation in the vapour phase at pressures as low as 0·5 mm. (~ 10^{-5} mol./litre) satisfactorily accounts for the negative temperature-coefficient of self-quenching[9] and the phenomenon of delayed fluorescence[4].

The observation of an emission of this duration in concentrated pyrene solutions illustrates the remarkable resistance of the emitting species to collisional deactivation by the monomer or by solvent molecules. These properties of the collisionally formed excited dimer which has virtually the life-time of a triplet state and the multiplicity of a singlet state[5] are those of an ideal sensitizer, and it is not unlikely that it plays an important part in the physical processes associated with photosynthesis and with phenomena dependent on concentration observed in aromatic solutions. Since it is not a primary product of absorption and does not apparently exist in the ground-state, we suggest the term 'excimer' be used to distinguish it from the short-lived dimer excited directly in solutions exhibiting an absorption spectrum dependent on concentration.

We wish to express our thanks to Prof. G. J. Hoijtink and Dr. R. N. Dixon for enlightening discussions, and to the Royal Society for a grant-in-aid and the Safety in Mines Research Establishment for the loan of a spectrograph. One of us (E. H.) is grateful to the Department of Scientific and Industrial Research for the award of a maintenance grant.

BIOCHEMISTRY

Effects of Fatty Acids on the ^{32}P-Adenosine Triphosphate Exchange Reaction in Rat Liver Mitochondria

ATTENTION has been focused in recent years on the effects of fatty acids on phosphate metabolism. In 1956 it was shown[1] that decanoate uncouples oxidation from phosphorylation in rat kidney and brain mitochondria. It was also shown, in the same year[2], that fatty acids stimulate the latent adenosine triphosphatase activity of rat liver mitochondria, myristic acid being the most effective. Results of recent work[3] have shown that the phosphorus-32 turnover in Ehrlich ascites cells is markedly decreased in the presence of potassium decanoate; however, that of rat liver slices is more sensitive to decanoate than is the process of oxidative phosphorylation in rat liver mitochondria[4]. In isolated rat kidney and brain mitochondria, 0·6 mM decanoate is needed to decrease the P : O ratio by 50 per cent[1], and preliminary experiments with rat liver mitochondria have indicated that decanoate is approximately as active in this system.[4] In work with rat liver slices, 1·33 mM decanoate inhibited phosphorus-32 turnover in adenosine triphosphate by 75 per cent, but the oxidation of decanoate-1-^{14}C proceeded at a high and constant rate for 3 hr. at this concentration, indicating that there was still sufficient adenosine triphosphate for the initial activation step. It was therefore of interest to determine if the decrease in the rate of labelling of adenosine triphosphate with phosphorus-32 in liver slices is due to a decreased rate of synthesis of the triphosphate, or whether it is due to the fact that labelling takes place by a process which is particularly sensitive to the presence of fatty acids. The adenosine triphosphate–phosphorus-32 exchange reaction[5] might constitute such a process, and the effects of fatty acids on this reaction were investigated.

The methods used were essentially those described by Dawkins, Judah and Rees[6], and a summary of the results obtained is given in Table 1. At low concentrations, all the fatty acids investigated cause an increased rate of labelling of adenosine triphosphate with phosphorus-32, and at somewhat higher concentrations they give rise to increasing inhibitory effects. Decanoate, at a concentration of 0·05 mM, brings about a 57 per cent stimulation of the rate of exchange of phosphorus-32 with adenosine triphosphate. Increase in decanoate concentration to 0·2 mM leads to a decrease of 42 per cent. It appears, therefore, that the process of labelling of adenosine triphosphate with phosphorus-32 in rat liver mitochondria is more sensitive to decanoate than is the oxidative synthesis of adenosine triphosphate. This is in agreement with the observations reported above that the process of labelling of adenosine triphosphate in rat liver slices is more sensitive to decanoate than is oxidation of this fatty acid, a process which is known to be dependent on the continued oxidative synthesis of adenosine triphosphate. The labelling of adenosine triphosphate by phosphorus-32 in rat liver slices, therefore, probably occurs more rapidly by the adenosine triphosphate–phosphorus-32 exchange reaction than by true synthesis of the triphosphate, and it is the former process which is inhibited on addition of relatively low concentrations of decanoate to rat liver slices in the presence of phosphate-^{32}P.

Incubations were carried out for 20 min. at 20° C. in the medium described by Dawkins *et al.*[6] with mitochondria equivalent to 125 mgm. wet weight of rat liver tissue. Under these conditions, the exchange reaction in the control vessels followed a linear course for a period of more than 30 min. The reaction was terminated by the addition of 2 ml. of 10 per cent trichloracetic acid to the 2 ml. incubation medium. The radioactivity present in the adenosine triphosphate was determined as described by Dawkins *et al.*[6]. All figures in Table 1 refer to percentages of the control values obtained in the absence of added fatty acid and are averages of 2–6 separate determinations. The average value for the control in fourteen experiments was 28·0 µmoles ^{32}P-phosphate exchanged in 20 min./gm. original wet weight of liver.

Table 1. EFFECTS OF VARIOUS FATTY ACIDS AT DIFFERENT CONCENTRATIONS ON THE ADENOSINE TRIPHOSPHATE – PHOSPHORUS-32 EXCHANGE REACTION IN ISOLATED RAT LIVER MITOCHONDRIA

Fatty acid concentration (mM)	C_6	C_7	C_8	C_9	C_{10}	C_{11}	C_{12}	C_{13}	C_{14}	C_{15}	C_{16}
0	100	100	100	100	100	100	100	100	100	100	100
0·005								112	111	118	
0·01						115	127	100	118	119	
0·015					150						
0·02						139	112	83	105	145	
0·03				189	189	129	112	68	95	106	
0·04						107		18	54	93	
0·05				204	157		54		54		115
0·075				141			11				
0·08						33		5		66	78
0·1					114		9				
0·15			161		64	14			12	36	47
0·2				123	58						
0·25		124	183								
0·3	164	190	178	90	15						
0·45			161								
0·5	204	160	116	52							
0·6				32							
0·75		105	105								
0·9			76								
1·0	193	55	39								

The greatest inhibitory effect on the exchange reaction occurs with the C_{13} fatty acid, the effects of the C_{14}, C_{15} and C_{16} fatty acids being approximately equivalent to the C_{12}, C_{11} and C_{10} fatty acids respectively (Table 1). This may be correlated with the observation of Pressman and Lardy[2] that optimal stimulation of latent adenosine triphosphatase activity occurs with myristic acid (C_{14}).

The present results are of further interest in view of the recent report that the '*U*-factor', which is present in normal tissues and is capable of uncoupling oxidation from phosphorylation, has the properties of a fatty acid[7]. A rapid and extensive swelling of rat liver mitochondria is brought about on addition of 3 µM oleate[7]. It is possible that the increased rate of labelling of adenosine triphosphate in the present experiments at the lower concentrations of fatty acids (5 µM in the case of tridecanoate) may be due to an increase in mitochondrial permeability to phosphate or adenosine triphosphate consequent upon the swelling of the mitochondria under these conditions.

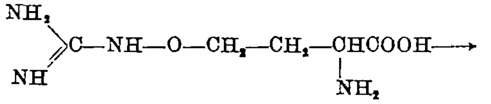
Chemical Degradation of Canavanine to Canaline

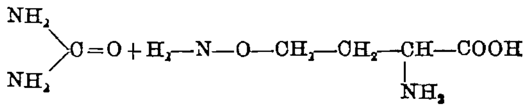
THE biologically interesting amino-acid, canaline, has been obtained by enzymatic cleavage of canavanine, a naturally occurring constituent of the Jack bean[1].

No chemical method capable of effecting this step has, however, been reported so far. While arginine, a close structural relative of canavanine, is impervious to acid hydrolysis, the latter undergoes cleavage to homoserine lactone (α-aminobutyrolactone) on heating with strong acids[2]. Canavanine, on the other hand, exhibits extraordinary stability in alkaline medium[3] while arginine is decomposed to ornithine by alkaline hydrolysis. In view of recent interest in canaline, it appeared desirable to re-examine the possibility of chemical degradation of the commercially available canavanine to canaline.



$$(NH_2)(NH{=})C\text{—}NH\text{—}O\text{—}CH_2\text{—}CH_2\text{—}CH(NH_2)COOH \longrightarrow$$

Canavanine



$$(NH_2)_2C{=}O + H_2\text{—}N\text{—}O\text{—}CH_2\text{—}CH_2\text{—}CH(NH_2)\text{—}COOH$$

Canaline

Accordingly, an attempt was made to force this reaction by vigorous alkaline hydrolysis. 1·37 gm. D,L-canavanine sulphate was heated with 25 per cent barium hydroxide for 48 hr. under refluxing conditions. The excess barium hydroxide was removed by addition of ammonium carbonate and filtration of the resulting barium carbonate. The reaction mixture was then evaporated to dryness in order to remove excess ammonia and redissolved in 100 ml. boiling water containing two mole equivalents of picric acid. The solution was allowed to cool to 25° and the beautifully crystalline dipicrate of canavanine (2 gm.) which had separated was filtered. On standing overnight, the mother liquors deposited a second crop of crystalline material (0·55 gm.) which was identified as D,L-canaline dipicrate, m.p. 189–191° after recrystallization from water. Analysis: calc. for $C_{16}H_{17}N_8O_{17}$: N, 18·92 per cent; found N, 19·0 per cent.

Treatment of canavanine with barium hydroxide under refluxing conditions for five days did not improve the yield of canaline. In order to prepare the free amino-acid, canaline dipicrate was dissolved in 70 volumes of hot water containing 2·5 mole equivalents of sulphuric acid. The picric acid was now removed from the solution by two successive extractions with nitrobenzene and ether. An excess of 'Dowex-3 *X*-4' resin (free amine form) was added to the colourless solution, the mixture filtered and the filtrate evaporated to dryness under reduced pressure. The residue when triturated with *iso*propanol yielded a solid which upon recrystallization from *iso*propanol–water gave D,L-canaline, m.p. 195–198° dec. Analysis: calc. for $C_4H_{10}N_2O_3$: N, 20·89 per cent; found N, 20·82 per cent.

Paper chromatograms of this product obtained by the small-scale technique of Rockland and Underwood[4] gave R_F values of 0·67 in the methyl-butynol–formic acid–water (69·5 : 1 : 29·5) system[5] and 0·78 in the ethanol–acetic acid–water (65 : 1 : 34) system and indicated the presence of a trace of impurity. L-Canaline obtained by enzymatic cleavage of L-canavanine exhibited chromatographic behaviour indistinguishable from that of the above product.

My thanks are due to Mr. J. Bush of these Laboratories for the preparation of L-canaline.

Maintenance of α-Ketoglutarate and Succinate Oxidation in E-Deficient Liver Homogenates by α-Tocopherol, a Tocopherol Metabolite, Menadione and Diphenylphenylenediamine

RATS on a *Torula* yeast diet deficient in vitamin E and factor 3 show a metabolic disturbance in liver slices, termed respiratory decline, 1–2 weeks prior to succumbing to necrotic liver degeneration[1]. Dietary supplementation of vitamin E as well as intraportal injection of the vitamin prevents the disturbance, whereas dietary factor 3 (and also selenite) alleviates the decline without, however, preventing it fully. The effects following dietary, intraportal, and *in vitro* application of a number of antioxidants have been analysed. A tocopherol metabolite[2] as well as diphenylphenylenediamine[3] are effective, *in vitro*, in preventing the respiratory failure of liver slices. While mitochondria of the deficient livers show an accelerated diminution of succinate oxidation in the presence of dinitropyridine nucleotide[4], homogenates of such livers, in previous work, did not show decline with glucose as substrate and optimal supplements of adenosine triphosphate and dinitropyridine nucleotide[1]. In this communication, a different homogenate system is described which shows respiratory decline with α-ketoglutarate or succinate as substrates. The preventive effects, *in vitro*, of tocopherol, the tocopherol metabolite (kindly supplied by Dr. Eric J. Simon of New York University College), menadione and diphenylphenylenediamine are demonstrated.

Weanling rats of the Fischer 344 strain were fed a basal 30 per cent *Torula* yeast diet described elsewhere[5]. Vitamin E was supplemented as 50 mgm. of D,L-α-tocopheryl acetate per 100 gm. ration. Factor 3 was introduced by the addition of 15 μgm. per cent of selenium (as sodium selenite). Some controls were fed McCollum's wheat casein diet[6]. The 10 per cent liver homogenates were made up in 0·25 *M* sucrose. The equivalent of 50 mgm. of tissue was added to 2·5 ml. of a medium containing the following ingredients: 300 μmoles sodium chloride, 12 μmoles potassium chloride, 40 μmoles of a sodium phosphate buffer at *p*H 7·4, and 4 μmoles of magnesium sulphate. The final volume was 3 ml. Water-insoluble supplements were added to the medium in ethanol (⩽ 0·02 ml.). In a separate series increased potency of tocopherol was achieved by rehomogenization of the vitamin with the liver homogenate. The additions, including substrates, were added at the expense of the medium and amounted to no more than 0·2 ml.

Under the experimental conditions described, oxygen consumption declines by approximately 69 per cent with α-ketoglutarate and 61 per cent with succinate as substrates (Table 1). This is completely prevented by dietary vitamin E if α-ketoglutarate is used. In this instance a slight, significant increase of oxidation is seen over the 1½-hr. incubation. It is important that fresh homogenates be used, since ageing in ice for several hours will nullify the protective effect of dietary tocopherol, so that decline will ensue. In contrast to the effect of tocopherol, dietary selenium is without effect in these systems.

Supplementation, *in vitro*, of α-tocopherol, the tocopherol metabolite of Simon *et al.*[7], menadione and diphenylphenylenediamine prevented the decline of α-ketoglutarate oxidation (Table 2). As little as 0·1 μgm. diphenylphenylenediamine afforded complete protection. When added directly to the medium, tocopherol was required at levels of about 50 μgm.

Table 1. EFFECT OF DIETARY α-TOCOPHEROL AND SELENITE ON DECLINE OF OXIDATION

Conditions and definitions are the same as in Table 1.

to prevent the phenomenon, and about 20 μgm. for a 50 per cent protective effect. Rehomogenizing of tocopherol with the liver homogenate produced a markedly higher activity. In this case, tocopherol prevented the respiratory lesion completely at about 5 μgm., and approximately 2–3 μgm. gave a 50 per cent effect. Whether this improvement is due only to a better distribution of the vitamin, to a subsequent activation, or to a metabolic alteration (formation of an active metabolite) remains to be clarified. The amount of tocopherol necessary to prevent this respiratory lesion is much less than that required for other *in vitro* systems[8,9] and more nearly approaches physiological quantities. The other supplements used did not require rehomogenization for maximal activity. When added directly to the medium, the tocopherol metabolite of Simon, 2-(3-hydroxy-3-methyl-5-carboxy)-pentyl-3,5,6-trimethylbenzoquinone, was approximately as active as tocopherol after it had been rehomogenized. Menadione, added directly, was approximately as active as tocopherol or its metabolite, in spite of the fact that the animals did not seem to suffer from a vitamin K deficiency (their prothrombin times, kindly assayed by Dr. A. Leitner, were normal). Coenzyme *Q* was without effect on this system.

With succinate as substrate, the same general picture is found. However, even in homogenates from normal controls (McCollum's wheat-casein diet) oxygen consumption shows a slow decline (< 30 per cent), probably related to accumulation of oxalacetic acid[10]. By dietary application of tocopherol as well as by addition of tocopherol, the tocopherol–metabolite of Simon, menadione or diphenylphenylenediamine to vitamin E-deficient homogenates, the decline of succinate oxidation is brought back from about 61 per cent to this level of less than 30 per cent. However, for these *in vitro* effects on succinate oxidation, much higher quantities of the supplements were required than with α-ketoglutarate. This may be related to the particulate nature of the succinate system.

Iodination of Specific Sites on Bovine Serum Albumin

SERUM albumins have been widely studied with respect to their ability to bind a wide range of substances[1–3]. Of particular interest are the nature of the binding sites and the question of whether the same sites are involved in binding different substances. Attempts have been made to elucidate the nature of the binding sites by determining the effect of chemical alteration of the serum albumin molecule on its binding properties[3,4]. Unfortunately direct chemical alteration does not permit evaluation of whether loss of binding is due to an alteration of the site itself or some non-specific alteration of the molecule elsewhere, resulting in either a subsequent disruption of the site or to a non-specific effect on the site.

In the case of antibodies against certain haptens, we have been able to show conclusively that the antibody site itself is affected by iodination. This was done by comparing antibody activity after iodination in the presence and absence of specific hapten[5]. Koshland *et al.*[6] have recently presented supporting evidence.

We have now been able to prove that iodination affects the actual sites on bovine serum albumin which are capable of binding *p*-iodobenzoate ion. This was done by iodinating bovine serum albumin in the presence and also in the absence of *p*-iodobenzoate ion. The latter has been shown to be bound by bovine serum albumin[7]. The bovine serum albumin used was the 'Pentex' crystallized product. The iodination was carried out in the presence or absence of iodobenzoate ion in glycine buffer of *p*H 9 by adding a solution of hypoiodite labelled with iodine-131 in the same buffer[8]. After iodination the protein solutions were dialysed against four changes of 10 l. of buffer at 5° over a period of 4 days to remove unbound iodide and *p*-iodobenzoate ion. Binding of *p*-iodobenzoate or methyl orange to bovine serum albumin preparations were carried out at *p*H 8·0 in the same manner as described previously for binding to anti-azobenzoate antibody[9]. Protein concentration was determined by Nessler reaction. Binding of iodobenzoate and methyl orange was determined by radiolabile[9] and spectrophotometric[10] methods respectively. Radioactive *p*-iodobenzoate was described previously[11]. The results are shown in Table 1.

When iodination was carried out in the absence of *p*-iodobenzoate so that an average of 43·8 iodine atoms were fixed per bovine serum albumin molecule, there was a marked decrease in the ability of the protein to bind *p*-iodobenzoate ion. However, when iodination was carried out in the presence of 0·02 *M* *p*-iodobenzoate to essentially the same extent, that is, 44·8 groups per bovine serum albumin molecule, the ability of the protein to bind *p*-iodobenzoate remained essentially unchanged. These results show that the part of the bovine serum albumin molecule which binds *p*-iodobenzoate ion is affected by the iodination process and contains an amino-acid remnant capable of being iodinated or oxidized by iodine since the site can be protected against alteration by carrying out the iodination in the presence of *p*-iodobenzoate ion. The facts that iodination was carried to the same extent for both preparations, and that essentially no effect on the binding of *p*-iodobenzoate was found when iodination is carried out in the presence of iodobenzoate, prove that the loss of binding power cannot be due to a non-specific effect of iodination on the protein molecule as a whole.

Table 1. BINDING ACTIVITY OF IODINATED BOVINE SERUM ALBUMIN – SPECIFIC PROTECTION OF SITES CAPABLE OF BINDING *p*-IODOBENZOATE*

Treatment of bovine serum albumin	Iodine atoms per bovine serum albumin molecule	Iodobenzoate bound†,‡		Methyl orange bound†,§	
		Concentration ($M \times 10^5$)	Moles per mole protein	Concentration ($M \times 10^4$)	Moles per mole protein
Untreated	0	3·8	1 1	1·53	4·7
Iodinated in presence of 0 02 *M* iodobenzoate	44·8	3 2	1·0	0 96	2 9
Iodinated without protection	43·8	1·5	0 5	0 96	2·9

* Bovine serum albumin or iodinated bovine serum albumin concentration, 2 mgm./ml.

† All samples were dialysed against common outer reservoir.

‡ Free iodobenzoate concentration, 1·2 × 10^{-5} *M*.

§ Free methyl orange concentration, 1 17 × 10^{-4} *M*.

It is of interest that the ability to bind methyl orange dropped appreciably and to the same extent (with these experimental conditions) during iodination regardless of whether the iodination was carried out in the presence or absence of *p*-iodobenzoate ion. Iodination experiments were not carried out in the presence of methyl orange.

The fact that the binding activity of both preparations for methyl orange was decreased equally indicates that methyl orange is bound at sites other than those at which the *p*-iodobenzoate is bound, and is a further indication that the binding of various substances to bovine serum albumin does not always involve the same sites.

5-Hydroxyindoles in Human Cerebrospinal Fluids

A MODIFICATION of the method described by Weissbach, Waalkes and Udenfriend[1] has been used for estimating the concentration of 5-hydroxyindoles in human cerebrospinal fluid. This is an estimation by fluorescence after protein precipitation using zinc hydroxide.

The first series of observations was made on two groups of patients on ventricular drainage in a neurosurgical ward. Group 1 of these patients (Table 1) were all hydrocephalic and had been previously showing high concentrations of protein in the cerebrospinal fluid for long periods of time. The 5-hydroxyindole concentrations were extremely high. Group 2, consisting of patients with a history of brain injuries or brain operations, had not been showing prolonged high protein concentrations in the cerebrospinal fluid and the 5-hydroxyindole figures were significantly lower than in group 1.

In one of the samples of cerebrospinal fluid from group 1 it was possible to identify 5-hydroxyindolyl-3-acetic acid by paper chromatography, colour reactions and fluorescence characteristics. Attempts at detecting 5-hydroxytryptamine were made in three

Table 1

Type of patient	No. of patients	Mean concentration 5-OH indoles ngm./ml.	Significance of difference
Group 1	4	313 ± 51*	$P < 0{\cdot}001$
Group 2	4	83 ± 15	

* ± *S.E.* of the mean.

instances with negative results (concentration < 1 ngm./ml.).

A second series of investigations is in progress on the 5-hydroxyindole concentration in lumbar cerebrospinal fluids. A comparison has been made between neurological patients requiring diagnostic air encephalography and psychiatric patients suffering from depressive psychoses. Table 2 shows a significantly lower concentration of 5-hydroxyindoles in the latter group.

Table 2

Type of patient	No. of patients	Mean concentration 5-OH indoles ngm./ml.	
Neurological patients	10	32·2 ± 2·8*	Significance of difference
Depressive psychoses	9	13·2 ± 2·5	$P < 0{\cdot}001$

Detection of N-Oxides of the Pyrrolizidine Alkaloids

Reagents for the detection of alkaloidal N-oxides on paper chromatograms are few and are usually rather insensitive or of low selectivity. Reaction with acetic anhydride, which is known to produce highly coloured by-products with the N-oxides of many alkaloids[1], provides sensitive and characteristic tests for those of the pyrrolizidine series.

Paper chromatograms are dipped in acetic anhydride/benzene/petrol ether (1 : 4 : 5 v/v), hung at room temperature for not longer than 2 min., and then placed in an air oven at 90–100° C. N-oxide spots become fluorescent in ultra-violet light and also develop visible colour.

The fluorescence is excited by ultra-violet lamps having maximum emission either at 3650 or at 2536 Å.; but background fluorescence is less with the former and so sensitivity is greater. Maximum fluorescence results after heating usually for 10–15 min., and thereafter lessens either in the oven or at room temperature. N-oxides of alkaloids derived from heliotridine or retronecine produce a golden-yellow fluorescence detectable with 2–3 μgm./cm.^{2}; those of supinine a medium brown, of sarracine a bluish-white and of anagyroidine (after 30 min.) a light yellow fluorescence, all detectable at 5 μgm./cm.^{2}.

The visible colour becomes maximal after the same period of heating but is permanent. With N-oxides of alkaloids derived from heliotridine or retronecine, it is dark brown, detectable at 5–10 μgm./cm.^{2}. Supinine N-oxide yields a warm brown with greater sensitivity and sarracine and anagyroidine N-oxides, light browns with less sensitivity.

Epilupinine N-oxide, not of the pyrrolizidine series, gives a bluish-white fluorescence and a weak orange-brown colour, and it is likely that N-oxides of some other alkaloidal groups would also be detectable.

(+) S-Methyl-L-Cysteine Sulphoxide: an Inhibitor of Aspartic Acid Utilization in *Leuconostoc mesenteroides*

The dextro (+) form of S-methyl-L-cysteine sulphoxide has been isolated from turnips[1] and from cabbages[2], and its widespread occurrence in crucifers has been inferred from chromatographic evidence[1,2]. The next higher homologue, methionine sulphoxide, acts as an inhibitor of glutamic acid utilization by *Lactobacillus arabinosus*[3,4]. This structural relationship suggested that S-methyl-L-cysteine sulphoxide might act as an inhibitor of aspartic acid in an analogous manner. The two diastereoisomeric sulphoxides of S-methyl-L-cysteine ((+) and (–) S-methyl-L-cysteine sulphoxide) were tested as aspartic acid antimetabolites in *Leuconostoc mesenteroides*. The natural isomer (+) S-methyl-L-cysteine sulphoxide inhibits the utilization of aspartic acid, but (–) S-methyl-L-cysteine sulphoxide has no measurable activity. On several counts this system can be contrasted with the methionine sulphoxide–glutamic acid system.

L. mesenteroides (*ATCC* 8042) was maintained on liver tryptone agar between trials and on liver tryptone broth prior to use. The complete medium of Steele *et al.*[5] with the exclusion of aspartic acid and asparagine was used in inhibition studies. In general, the final volume per tube was 9 ml. and growth was measured by titrating the acid produced after 72 hr. incubation at 37° C. Over a range of 0–25 μgm. aspartic acid per tube-growth is linear.

With (+) S-methyl-L-cysteine sulphoxide, consistent growth inhibition was apparent from turbidity observations and acid measurements, whereas (–) S-methyl-L-cysteine sulphoxide had no detectable effect. An equimolar mixture of the (+) and (–) forms had an activity equivalent to the (+) form

Table 1. Effect of S-Methyl-L-Cysteine Sulphoxide (MCSO) on the Utilization of L-Aspartic Acid by *Leuconostoc mesenteroides*. Each figure represents the mean of three determinations

L-aspartic acid μmoles	Molar ratio sulphoxide : aspartic	Ml. of 0·02 *N* acid produced			Inhibition by (+) MCSO (per cent)
		Control	(+) MCSO	(–) MCSO	
0·11	100 . 1	5·98	5·50	6·25	8
0·15	133 : 1	8·87	7·49	8·71	15
0·11	1,000 : 1	5·98	2·75	6·05	54

Table 2. EFFECT OF L-ASPARAGINE AND METHYL CYSTEINE SULPHONE ON THE UTILIZATION OF L-ASPARTIC ACID BY *Leuconostoc mesenteroides*

Additions	Amount	Growth*
Aspartic acid	0·1 μmole	6·38
Aspartic acid + MOSO	0 1 μmole 100 μmole	2 06
Aspartic acid + asparagine	0·1 μmole 0·1 μmole	7 52
Aspartic acid + asparagine + MOSO	0·1 μmole 0·1 μmole 100 μmole	2 33
Aspartic acid + MOSO$_2$	0·1 μmole 100 μmole	7 58

* Ml. of 0 02 *N* acid produced in 72 hr. incubation at 37° C.; final volume. 10 ml. per tube.

alone. The inhibition of growth by (+) S-methyl-L-cysteine sulphoxide was overcome by the addition of more L-aspartic acid. Some typical results which show the magnitude of inhibition are summarized in Table 1. A molar ratio of 1,000 : 1 is required for 54 per cent inhibition.

In the Borek and Waelsch system[6], methionine sulphoxide, in 35 : 1 ratio, inhibits glutamic acid utilization to the extent of 88 per cent. In direct contrast to the system described in the present communication, the (−) form of methionine sulphoxide possesses the greater activity; however, it is only 2½ times as active as the (+) isomer[7].

Another difference between these two systems is encountered in comparing the relative activities of the sulphone derivatives. In the aspartic system, methyl cysteine sulphone has shown no inhibition at a ratio of 1,000 : 1 (Table 2); whereas Borek and Waelsch[6] observed that methionine sulphone, in 84 : 1 ratio, gave a 72 per cent inhibition of glutamic acid utilization.

With *L. arabinosus* the growth inhibition by methionine sulphoxide is completely eliminated by replacing the glutamic acid with an equivalent amount of glutamine[4]. It has been concluded that methionine sulphoxide affects the amidation of glutamic acid. In the *L. mesenteroides* system asparagine has no growth-promoting effects in the absence of aspartic acid; however, the different manner in which aspartic acid and glutamic acid are utilized may be due to differences in the organisms. If an equivalent amount of asparagine is added in the presence of aspartic acid there is no sparing effect on the aspartic acid inhibition by (+) S-methyl-L-cysteine sulphoxide (Table 2). In the *L. mesenteroides* system (+) S-methyl-L-cysteine sulphoxide is evidently affecting some reaction other than the amidation of aspartic acid.

PHYSIOLOGY

Non-Identity of Triosephosphate Dehydrogenase of Adult Male and Nymph Development Stages of *Triatoma infestans*

WHILE studying the mode of action of 2,2-*bis*-(*p*-chlorophenyl)-1,1,1-trichloroethane (DDT) on *Triatoma infestans* it was found that an *in vivo* dose of both DDT and 2,2-*bis*-(*p*-chlorophenyl)-1,1-dichloroethylene (DDE) which inhibited triosephosphate dehydrogenase derived from male adult specimens of *T. infestans* was without effect on the enzyme derived from nymph specimens (our unpublished observations). This different behaviour of triosephosphate dehydrogenase derived from two different stages in development of the same insect has been also observed *in vitro*. Extracts for enzymatic assay were prepared as follows. The thoraces and legs of male or nymph specimens were ground in a mortar with 0·15 *M* potassium chloride and extracted during 60 min. at 2°; the resulting brei was filtered through cheese-cloth to remove pieces of cuticle and the filtrate centrifuged at 20,000*g* for 60 min. at 2°; the supernatant fluid was finally filtered through Whatman No. 1 paper and used as such as a source of enzyme. Triosephosphate dehydrogenase was assayed as described elsewhere[1].

Table 1 shows that DDT or DDE added in acetone, at a final concentration of $2 \cdot 8 \times 10^{-5} M$, produced 26 and 28 per cent inhibition respectively of adult male triosephosphate dehydrogenase, while no effect was observed on the nymph enzyme. These observations suggested that although adult male and nymph triosephosphate dehydrogenase catalyse similar reactions, they may not be identical with each other. Evidence supporting this view was obtained by the use of specific antibodies. Specific antisera were prepared according to Freund *et al.*[2]. The antiserum against male adult triosephosphate dehydrogenase markedly inhibited the activity of male triosephosphate dehydrogenase; by contrast, the antiserum against nymph triosephosphate dehydrogenase did not affect the activity of the male enzyme, but strongly inhibited the activity of the nymph enzyme (Fig. 1).

Table 1. EFFECT OF DDT AND DDE ON TRIOSEPHOSPHATE DEHYDROGENASE ACTIVITY OF ADULT MALE AND NYMPH EXTRACTS OF *Triatoma infestans*

Additions	Male extracts	Nymph extracts
	Change in optical density/min./mgm. protein	
None	0·300	0 119
DDT	0·223	0·123
DDE	0·216	0·130

System: 100 μmoles pyrophosphate buffer, *p*H 8·5; 2 4 μmoles diphosphopyridine nucleotide; 10 μmoles magnesium chloride; 10 μmoles arsenate; 10 μmoles 1-cysteine; 0·5 μmole 3-phosphoglyceraldehyde to start the reaction; DDT and DDE added in 10 μl. acetone, final molarity, $2\ 8 \times 10^{-5} M$; 0 05 ml. male extract and 0·1 ml. nymph extract: the cuvettes without DDT or DDE had 10 μl. acetone as control; the blank cuvettes contained the same components as the experimental cuvettes with the exception of 3-phosphoglyceraldehyde. Final volume, 3 0 ml.

While studies on the effect of DDT on various enzymatic systems have so far failed to clarify the mode of action of DDT, the above observations may have some bearing on the problem of the resistance towards DDT, since adult male specimens of *T. infestans* are quite susceptible to DDT, whereas nymphs are relatively resistant.

This work was supported by grant *E*-2300 of the Division of Research Grants and Fellowships of the

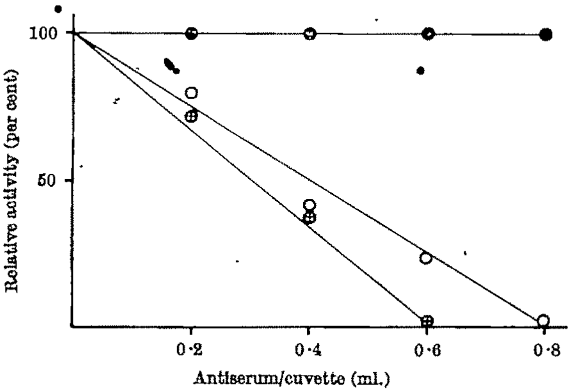

Fig. 1. The effect of specific antisera on the triosephosphate dehydrogenase of male and nymph specimens of *T. infestans*. System: 100 μmoles pyrophosphate buffer, *p*H 8 5; 2·4 μmoles diphosphopyridine nucleotide; 10 μmoles magnesium chloride, 10 μmoles arsenate; 10 μmoles 1-cysteine; male or nymph extracts to give a change in optical density of about 0 040 per min. All components were incubated in the presence of variable amounts of antiserum, as shown, during 20 min. at room temperature (25°) and then the reaction started by the addition of 0·5 μmole 3-phosphoglyceraldehyde. Adequate controls with normal serum were carried out. Final volume, 3·0 ml.

Xanthine Dehydrogenase in the Silkworm, *Bombyx mori* L.

Although considerable amounts of uric acid have been demonstrated in the silkworm larva, *Bombyx mori*[1,2], very little is known about the intermediary purine metabolism in insects[3-5]. In the formation of uric acid it is the xanthine enzyme system which catalyses the oxidation of purine derivatives xanthine and hypoxanthine to the acid.

Recent studies on purine metabolism[5] have disclosed that the xanthine enzyme system in the silkworm moth behaves as dehydrogenase just like that of chicken liver[6]. It is highly probable that in the silkworm xanthine dehydrogenase plays an active part in uric acid formation.

The experiments described here were performed to establish the principal sites of xanthine dehydrogenase activity of the various organs and tissues in silkworm larvæ, demonstrating the existence of purine metabolic system.

Samples of the insect tissues were dissected out and washed to free them from adhering particles, and after removing the water with filter paper the tissues were weighed, then homogenized in 0·1 *M* pyrophosphate buffer (*p*H 8·3) to obtain 10 per cent homogenate.

As the xanthine enzyme catalyses the oxidation of xanthine by molecular oxygen and by other hydrogen acceptors such as methylene blue, both the aerobic manometric method and the anaerobic Thunberg method are suitable for the measurement of the enzyme activity.

Table 1. OXYGEN CONSUMPTION AND URIC ACID FORMATION FROM XANTHINE IN THE TISSUES (5TH INSTAR)

Materials	Oxygen uptake (μl./ml./hr.)		Uric acid formation (optical density/ml./hr.)	
	With methylene blue	Without methylene blue	With methylene blue	Without methylene blue
Digestive organ	10·90	1·60	0·232	0·016
Malpighian tube	15·70	0·20	0·258	0·001
Fat body	39·10	3·40	0 308	0·016
Integument	3 00	0·90	—	—
Blood	4·00	0 70	0 011	0 003

For the aerobic measurement[6-8], 1 ml. of the tissue homogenate was added to the main compartment of a Warburg flask containing 0·2 ml. of either distilled water or methylene blue (0·0113 *M*), the side arm and centre well of which carried 0·3 ml. of 0·025 *M* xanthine solution in 0·005 *M* sodium hydroxide and 0·2 ml. of 20 per cent solution of potassium hydroxide respectively, making the total fluid volume 1·7 ml. Oxygen uptake was measured manometrically at 37° C. with air as gas phase. Xanthine solution in the side arm was tipped in after 10 min. temperature equilibrium. Readings were taken every 10 min. for 60 min., and thereafter the reaction mixture was adopted to estimate the uric acid formation by Brown's methods[9].

For the anaerobic measurement[10-12], the enzyme activity in the tissues was measured using the anaerobic reduction of the colourless dye 2,3,5-triphenyl tetrazolium chloride in a Thunberg tube. The reaction was carried out by mixing the following solution (maintained at 37° C. for 40 min.): 1 ml. of 0·1 *M* pyrophosphate buffer (*p*H 8·3) and 1 ml. of tissue homogenate in the body of Thunberg tube, and 1 ml. of 10^{-3} *M* 2,3,5-triphenyl tetrazolium chloride solution and 1 ml. of xanthine (0·025 *M*) in the side arm. The reaction was stopped by 0·2 ml. of 20 per cent trichloroacetic acid, and the enzyme activity was expressed in optical density of the red formazan extracted with ethyl acetate.

Table 1 shows the xanthine dehydrogenase activity of the various tissues. The result clearly was demonstrated that the enzyme activity occurred in the digestive organ, Malpighian tube and fat-body preparations with methylene blue, but not without methylene blue.

However, little or no activity could be detected in the integument and blood with or without methylene blue. The enzyme activity of fat body was high in comparison with that of the digestive organ and Malpighian tube. Further, the tissue preparations described above could transform xanthine into uric acid only when methylene blue was used as hydrogen carrier. It is suggested that the enzyme in larvæ, like that of the silkworm moth, is essentially of dehydrogenase nature rather than oxidase.

The rate of reduction of 2,3,5-triphenyl tetrazolium chloride using xanthine as substrate is presented in Table 2. The result indicates that the homogenate from the digestive organ, Malpighian tube and fat-body reduced the 2,3,5-triphenyl tetrazolium chloride, except that from blood and integument. Xanthine dehydrogenase activity in these tissues is in general agreement with the experiment shown in Table 1 with methylene blue, using an aerobic procedure.

The 2,3,5-triphenyl tetrazolium chloride used in a Thunberg tube was demonstrated to be a satisfactory receptor of the xanthine dehydrogenase system in the

Table 2. REDUCTION OF 2,3,5-TRIPHENYL TETRAZOLIUM CHLORIDE BY THE XANTHINE DEHYDROGENASE IN THE TISSUES (5TH INSTAR)

Materials	Endogenous (*E*)	With substrate (*E*)
Digestive organ	0 030	0 086
Malpighian tube	0 097	0 301
Fat body	0·025	0·467
Integument	0·090	0 096
Blood	0 167	0·119

silkworm. The name of xanthine oxidase in chicken liver has been proposed as xanthine dehydrogenase by Remy, Richert and Westerfeld[6], only because the catalysis from xanthine to uric acid reacts more slowly with molecular oxygen than with methylene blue. Thus, in addition to the previous result it is further substantiated that the xanthine enzyme system in the silkworm is of a dehydrogenase character.

I wish to express my thanks to Prof. K. Hasegawa (Sericultural Laboratory) and Mr. A. Yoshida (Food and Nutrition Laboratory) for valuable advice and help throughout this work.

Body-Weight and Age in Relation to the Metabolic-Rate of the Young Pig

AN animal's maturity at birth is manifested in part by its degree of dependence on its environment, and by its changes in metabolic-rate with age as distinct from changes caused by its increasing size and varying body temperature. Some animals tend towards poikilothermy in the period immediately after birth, while others are only weakly homoeothermic[1]. Mount[2,3] has shown that new-born pigs, on the other hand, of ages from 1 hr. onwards, react to exposure to a temperature of 4° C. with a marked rise in metabolic-rate, thus showing characteristics of the adult homœotherm. Mount's findings, however, were not in agreement with those of Holub, Forman and Ježková[4], who concluded that thermogenesis in response to cold does not begin to appear in the young pig until the ninth day after birth.

The question to be considered here is whether oxygen consumption varies with age independently of concomitant changes in body-weight. Holub, Ježková and Forman[5] have found oxygen consumption per unit body-weight to be closely correlated both with age and with body-weight. Because of the high correlation between body-weight and age, however, it is necessary to consider these variables simultaneously to determine whether oxygen consumption varies with age independently of body-weight. In interpreting the results of the experiment described below, therefore, multivariate regression analyses[6] were used so that the relation with age could be studied when body-weight was held constant; variations in rectal temperature were also taken into account.

Table 1. PARTIAL REGRESSION COEFFICIENTS AND THEIR STANDARD ERRORS FOR LOG (TOTAL OXYGEN CONSUMPTION ML. PER MIN.) ON LOG (BODY-WEIGHT), RECTAL TEMPERATURE, AND AGE

	log (body-weight, kgm.)	Rectal temperature (° C.)	Age (hr.)
30° C. first week	0·610 ± 0 064	0·157 ± 0 035	0·000748 ± 0 000403
4° C. first week	0 562 ± 0 186	0 105 ± 0·029	0·001106 ± 0·000763
30° C. 1–5 weeks	0 684 ± 0 083	0 150 ± 0 038	−0 000372 ± 0 000126

The experiment involved 98 pigs in the first five weeks after birth. Oxygen consumption was used as the index of metabolic-rate and the investigation was carried out on three groups of pigs, differing in respect of the ambient temperature for the measurement, and age; these groups will be referred to as 30° C. first week, 4° C. first week and 30° C. 1–5 weeks. Log (total oxygen consumption per min.) was examined in relation to age, rectal temperature and log (body-weight). The partial regression coefficients and their standard errors for each of the three variables are given in Table 1, and the expressions for oxygen consumption-rates for single animals are given below for the three groups (1) 30° C. first week, (2) 4° C. first week and (3) 30° C. 1–5 weeks:

$$(1)\ 0{\cdot}0442\ B.W.^{0\,610}\ e^{0\,157\,R.T.}\ e^{0\,000748\,\mathrm{age}}$$

$$(2)\ 0{\cdot}7134\ B.W.^{0\,562}\ e^{0\,105\,R\,T}\ e^{0\,001106\,\mathrm{age}}$$

$$(3)\ 0{\cdot}0598\ B.W.^{0{\cdot}684}\ e^{0\,150\,R.T.}\ e^{-0\,000372\,\mathrm{age}}$$

where *B.W.* = body-weight (kgm.) and *R.T.* = rectal temperature (°C.); oxygen consumption-rate was measured in ml./min. and age in hours.

The relative effects of body-weight and age on oxygen consumption have been examined by calculating from the above expressions the effects of differences in body-weight for pigs of a given age, and the effects of differences in age for pigs of a given body-weight (rectal temperature was held constant at 39° C. in all cases). The age–weight regression shows

Table 2 (*a*). EFFECTS OF DIFFERENCES IN BODY-WEIGHT ON OXYGEN CONSUMPTION OF PIGS AT A GIVEN AGE

	Age (constant)	Body-weight (kgm.)	Oxygen consumption (ml./min.)	Difference
30° C. first week	3 days	1·50	27·6	
		1·86	31·5	3·9
4° C. first week	3 days	1 50	58·5	
		1·86	65 9	7 4
30° C. 1–5 weeks	3 weeks	3·83	43·6	
		5 68	57·0	13·4

Table 2 (*b*). EFFECTS OF DIFFERENCES IN AGE ON OXYGEN CONSUMPTION OF PIGS OF A GIVEN BODY-WEIGHT; THE AGE DIFFERENCES USED CORRESPOND TO THE WEIGHT DIFFERENCES IN TABLE 2 (*a*)

	Body-weight (constant)	Age	Oxygen consumption (ml./min.)	Differences
30° C. first week	1 68 kgm.	2 days	29·0	
		4 days	30·1	1·1
4° C. first week	1·68 kgm.	2 days	60·7	
		4 days	64 0	3·3
30° C. 1–5 weeks	4·75 kgm.	2 weeks	53 8	
		4 weeks	47·4	−6·4

that during the period between 2 and 4 days after birth, body-weight increased from 1·50 to 1·86 kgm. (mean = 1·68 kgm.). Thus the difference in oxygen consumption between 3-day-old pigs of weights 1·50 and 1·86 kgm. was compared with the difference in oxygen consumption between pigs aged 2 and 4 days but the same weight, 1·68 kgm. A similar procedure was adopted for the older pigs (1–5 weeks). The results of these calculations are given in Tables 2*a* and 2*b* and show that differences in body-weight had at least double the effect on oxygen consumption of corresponding differences in age. Indeed, during the first week, it is not certain whether age affected oxygen consumption at all; the individual partial regression coefficients for the first two groups shown in Table 1 were not significant but, taken together, there is a suggestion that oxygen consumption increases slightly with age (body-weight and rectal temperature fixed). From 1 to 5 weeks, the reduction in oxygen consumption with age (body-weight and rectal temperature fixed) was significant; possible reasons for this comparatively small effect will be discussed in a later paper.

As a result of this experiment, it appears that the changes in the oxygen consumption-rate of the young pig with age are of only minor importance when body-size and body-temperature changes have been taken into account. This conclusion considered in conjunction with the vigorous metabolic response of the newly born pig to cooling of its environment reported by Mount[3] suggests that thermogenesis is well developed at birth.

We are indebted to Dr. J. H. Gaddum for discussion of the statistical analysis of this investigation.

Determination of Small Rapid Volume Changes in a Muscle during Activity

A METHOD has been developed for measuring small rapid volume changes occurring in a muscle during a single twitch. In order to achieve the necessary sensitivity and speed of response, a capacitance transducer has been developed which uses a commercially available detector-amplifier circuit (the 'Dynagage', from Photocon Products). The changes are displayed on a cathode-ray oscilloscope. Single gastrocnemius and sartorius muscles from *Rana pipiens* are used.

Following a stimulus applied through a multi-electrode assembly, volume changes occur after a short latent period. An initial apparently small increase in volume precedes the main decrease of volume (Fig. 1), which is about 1·6 × 10^{-5} c.c./gm. in gastrocnemius and 5 × 10^{-6} c.c./gm. in sartorius muscle.

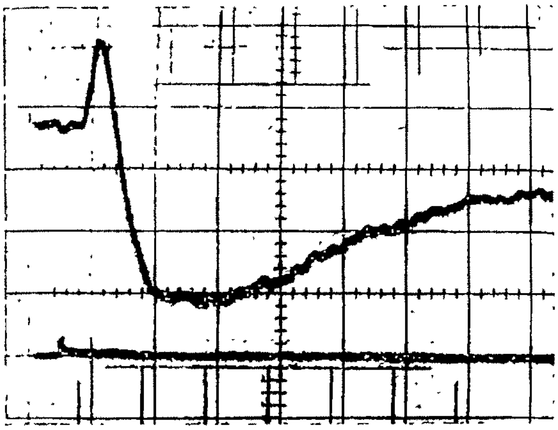

Fig. 1. Record of volume changes at 18° C., in single frog sartorius muscle. The muscle is held isometrically at reference length and is stimulated with a single shock. The stimulus point is indicated below the volume record. Each large division represents 20 msec. on the abscissa and 0 3 × 10^{-6} c.c. on the ordinate. Uncorrected for delay

Analysis to correct for delays in the chamber using a step-function volume-change from a loudspeaker coil movement showed that the early increase is actually almost as large as the later decrease in volume, and has almost the same time course as latency relaxation (Sandow, 1944) and as early transparency changes in a twitch (D. K. Hill, 1953).

The increase in volume is rapidly reversed and the maximum decrement in volume is reached appreciably before the peak of isometric tension. At the end of relaxation a decrease in volume persists (Fig. 1), and at 0° C. almost no volume recovery occurs in sartorius muscle. It therefore seems unlikely that these volume changes result from internal pressure changes due to muscle tension (A. V. Hill, 1948), and perhaps the time course of decrease in volume reflects that of the developing active state.

In view of the continuing inability to demonstrate chemical changes during a single contraction, it may be well to re-estimate the information, which measurements such as volume and opacity changes can provide, on the events both of the excitation coupling and on protein organization in contraction.

HÆMATOLOGY

A Hæmoglobin-binding β-Globulin in Human Serum

A NUMBER of human serum proteins have the property of forming definite compounds with hæmoglobin. The term haptoglobin has been applied to them by Jayle[1,2], who was able to isolate them by salt fractionation and characterize them as α_2-globulins by electrophoresis. In several studies using paper electrophoresis, hæmoglobin-binding proteins have been detected in the α_2 region. Hæmoglobin has also been found in the β-globulin region, especially when large amounts are present, but since free hæmoglobin itself migrates as a β-globulin, it has been assumed that this represents uncombined hæmoglobin. Neale, Aber and Northam[3] found that a discrete band in the β-globulin region reacted with benzidine reagents, but did not appear to be free hæmoglobin. They suggested that a β-globulin binds hæmoglobin as well as an α_2-globulin.

The technique of immuno-electrophoresis[4] has certain advantages in investigating the problem since the effect of free hæmoglobin may be largely ruled out. After the anti-serum diffusion stage, excess protein was removed by washing the agar extensively with water and the preparations stained for hæmoglobin with benzidine, using sodium nitroprusside as a stabilizing agent[5]. Two lines stained blue with benzidine, one in the α_2 region and one in the β region (Fig. 1). The α_2 line can just be seen to be doubled in some individuals. Combination with hæmoglobin does not noticeably affect the electrophoretic mobility of these components, since the same lines can be seen in the same place in hæmoglobin-free serum. The α_2 line or lines appear to correspond with the now well-known haptoglobins 1 and 2 of Smithies[6], while the fact that only two lines can be detected lends some support to the hypothesis of Allison[7] that the numerous haptoglobins found in some individuals by starch-gel electrophoresis are polymers, either of the type 2 haptoglobin with itself or with type 1.

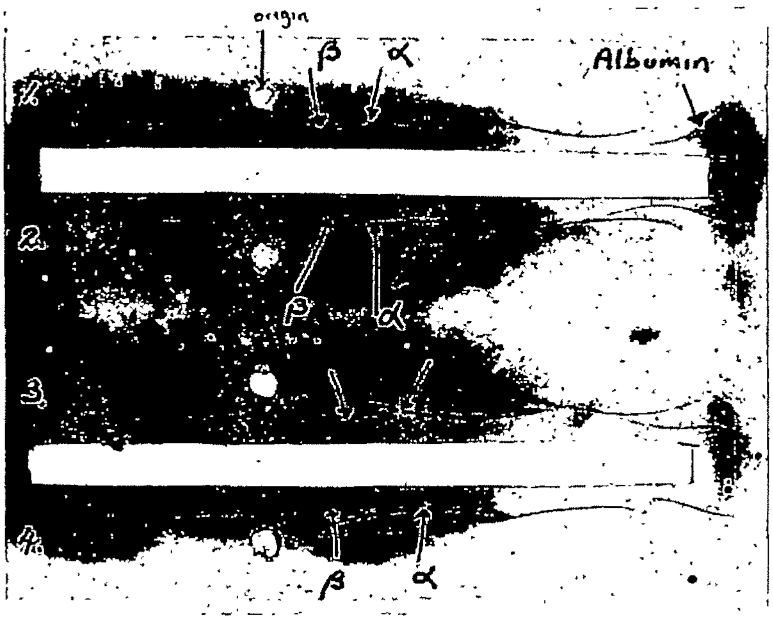

Fig. 1. Immunoelectrophoresis patterns of four different sera after benzidine staining. Each serum contained 200 mgm. hæmoglobin per 100 ml. The two lines which stained blue with benzidine are marked α and β

The line in the β region cannot be due to free hæmoglobin, both because it is readily seen in serum which contains no hæmoglobin and because hæmoglobin itself gives no precipitin line with the anti-serum used (horse anti-human serum, Institut Pasteur, Paris). Burtin *et al.*[8] have reported that on storage the α_2-haptoglobins become transformed into a component with β mobility. The hæmoglobin-binding β-globulin detected in immuno-electrophoresis does not represent this converted form of the α_2-haptoglobin since it is present in fresh serum. Furthermore in very old sera the α_2-haptoglobin has a much lower electrophoretic mobility than in fresh sera, but gives a precipitin arc quite different from that shown by the hæmoglobin-binding β-globulin. It is possible that the β-globulin-antibody complex, when formed in the presence of free hæmoglobin, is capable of binding it, while the β-globulin alone does not. Other arcs formed in the presence of free hæmoglobin do not show binding, however, and it is most unlikely that this was the source of the benzidine staining found.

These results suggest strongly that there is a β-globulin in human serum capable of binding hæmoglobin, in addition to the well-known α_2-globulins. Studies in which increasing amounts of hæmoglobin have been added to serum indicate that the β-haptoglobin has a lower affinity for hæmoglobin than the α_2-haptoglobins, and it does not start to bind hæmoglobin until the α_2-haptoglobin is substantially saturated. It has been detected in each of thirty sera and two cord sera so far examined, and unlike the α_2-haptoglobins it does not show marked individual variation, at least by this technique. It is not transferrin, since it forms an arc just inside that of transferrin in immunoelectrophoresis. However, its electrophoretic mobility on paper and in starch gels, solubility in ammonium sulphate (just soluble in half saturated) and its behaviour on ion-exchange cellulose columns are all closely similar to those of transferrin.

Although the β-globulin described appears to have a much smaller capacity for hæmoglobin than the α_2-haptoglobins, which are undoubtedly the major haptoglobins quantitatively, its existence should be taken into account in determining the hæmoglobin-binding capacity of serum; some existing methods appear to exclude it. It may also take a significant physiological role in those individuals who normally have a very low level of α_2-haptoglobin. In one such case the β-haptoglobin was present but did not appear to be elevated.

I am much indebted to the British Empire Cancer Campaign for financial support and to the Photographic Department for Fig. 1.

Fibrinogenolysis in Joints

THE following observations were made in the course of an investigation into the reasons for the apparent failure of blood to clot when shed into synovial joints.

Growing rabbits, 3–4 months old, were used. Plasma was prepared from citrated blood (two volumes 3·8 per cent sodium citrate to eight of blood). Veterinary nembutal was used as anæsthetic. The rabbit's knee joint was injected with plasma until full (2·0–2·5 ml.). A control specimen was placed in a siliconed tube in a water-bath at 37° C. At pre-set intervals 0·25-ml. samples of fluid were aspirated for fibrinogen estimations. At the end of the experiment the animal was killed by excess nembutal or bleeding. The knee joint was then opened, free fluid collected and clots thoroughly searched for. Any clot found was retained for estimation of fibrin content.

Fibrinogen estimations were carried out in duplicate using King's Nesslerization method[1] modified only by the use of thrombin (Maw's, 10–20 units) to precipitate the fibrin instead of simple recalcification. The duplicate results were averaged. Plasma clots recovered from the joints were washed in saline once, and in distilled water three times, with firm expression of the contained fluid between glass slides at each stage. The fibrin content was estimated by Nesslerization.

The findings in fifteen experiments are exemplified in Fig. 1. The fibrinogen-level falls to zero in 1–1¼ hr. Plasma incubated *in vitro* shows no fall or only a relatively slight drop in fibrinogen-level over the same period.

Recovery of the full volume of plasma injected was not achieved, about half leaking out of the joint during the experiment. In three experiments no clot was found in exploring the joint. Analysis of the residual clot when present in no instance revealed enough fibrin to account for the observed fall of fibrinogen-levels in the volume of fluid recovered, let alone in that injected. In the experiment illustrated 0·33 mgm. fibrin was recovered from the joint as clot. The loss of fibrinogen observed in the volume of fluid recovered was equivalent to 1·29 mgm. fibrin. As fibrinogen was lost almost certainly from a greater volume of plasma than that recovered by aspiration, the total fibrinogen to be accounted for is greater than this figure.

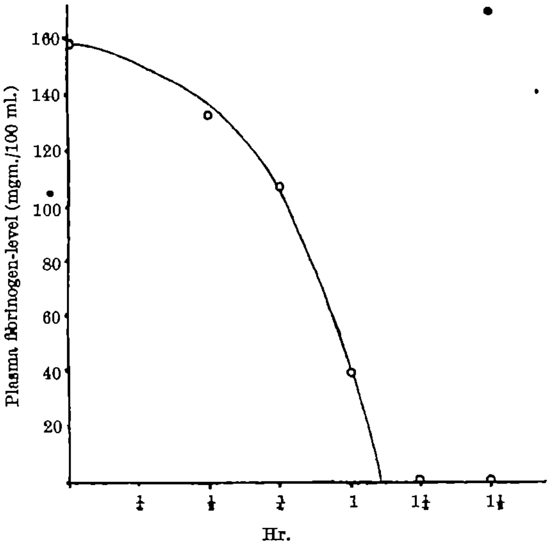

Fig. 1. Fibrinogen-levels of citrated plasma in the knee joint of the rabbit

Although it was difficult to avoid the entry of thrombin and the formation of small clots, it seemed that the greater part of the fibrinogen in the joint was destroyed by lysis.

In further experiments it was found that fibrinogenolysis does not occur in the dead animal; it is much slower in fully grown animals than in the young; it is completely inhibited by heparin (5 units/ml.) and is inhibited by crystalline soya bean trypsin inhibitor at a concentration of 1 mgm./ml., but not at 0·13 mgm./ml.

These experiments suggest that, in contrast to most *in vitro* experiments, *in vivo* conditions may exist in which fibrinogenolysis occurs quite rapidly while, at the same time, fibrinolysis occurs but slowly, if at all. The possibility that fibrinogenolysis is caused by the activation of plasmin is supported by the observed inhibitory effects of heparin and soya bean inhibitor. The presence of plasmin activators in joint tissues has already been reported[2,3].

Intra-articular fibrinogenolysis could be one factor responsible for the partial failure of blood to clot when shed into synovial joints.

HISTOLOGY

Localization of Amino-acids for Histochemical Estimation

SERRA[1] attempted to determine total amino-acids in frozen tissue sections with alloxan and ninhydrin. However, the coloured products diffused rapidly from their original sites so that localization was not possible. Other methods have also been found to be unsatisfactory for the same reason[2,3]. Certain amino-acids have been successfully fixed *in situ*[1,4,5], but these probably cannot be used as a reliable indication of total amino-acids in the tissues.

To circumvent the above difficulties, the following method was developed which prevents diffusion of the acids and their ninhydrin products from their original sites. Kill, dehydrate and fix the tissue with anhydrous, peroxide-free dioxane (1,4-diethylene dioxide). Be sure that the dioxane is entirely peroxide-free because even traces of peroxides depress colour development. Fix the tissue in three changes of dioxane under partial vacuum over a period of 24 hr. or longer, depending upon the size of the piece of tissue. Clear in steps with mixtures of dioxane and chloroform to pure chloroform. Infiltrate with 'Tissuemat'. Section to desired thickness and mount adjacent sections on duplicate slides covered with a thin film of Haupt's adhesive[6,7]. Duplicate slides containing adjacent sections are necessary to distinguish between the relative contribution of protein and free amino-acids to the overall colour density after the ninhydrin reaction. Deparaffinize the sections in two changes of xylol. For determining protein only, dissolve out the amino-acids on one slide by taking the slide through absolute ethanol to 70 per cent ethanol and then to dioxane. For total amino-acids plus protein, take the second slide directly from xylol into dioxane. Change the dioxane once, and after 5 min. allow the slide to stand for 2 min. in a 1 per cent solution of ninhydrin in dioxane. Drain off the excess solution and place the slide in a covered Coplin jar preheated to 100° C. and containing a little ethanol at the bottom to keep the atmosphere in the jar saturated with ethanol. Develop the colour for 45 min. in an oven at 100° C. Take care that the sections are not immersed in the ethanol since this results in diffusion of the ninhydrin products. Clear the sections in two changes of xylol and mount in Fisher 'Permount'.

The colour density of one cell or a group of cells is determined microphotometrically with a simplified apparatus of the type used by Pollister and Moses[8], using a 570-mμ filter. Measurements may be made at any time up to 24 hr. After 24 hr. the colour produced by amino-acids begins to fade; but that produced by protein is stable for 7 days or longer (Fig. 1).

The relationship between colour density and concentration was determined with glycine to test the feasibility of the procedure. Glycine solutions at 200, 400, 600 and 1,000 p.p.m. were prepared. Sections were deparaffinized and the endogenous amino-acids were removed with 70 per cent ethanol. The slides were drained thoroughly, air dried and then the sections were infiltrated with glycine at each of the above concentrations. The glycine was then fixed in the tissue with dioxane and taken through the whole procedure. The amino-acid concentration was determined in cortical and procambial cells, along with comparable control sections containing only protein background. The values after correction for protein background are plotted in Fig. 2. The results show that the optical density after correction for protein background is directly proportional to the amount of amino-acid in the infiltrating solution.

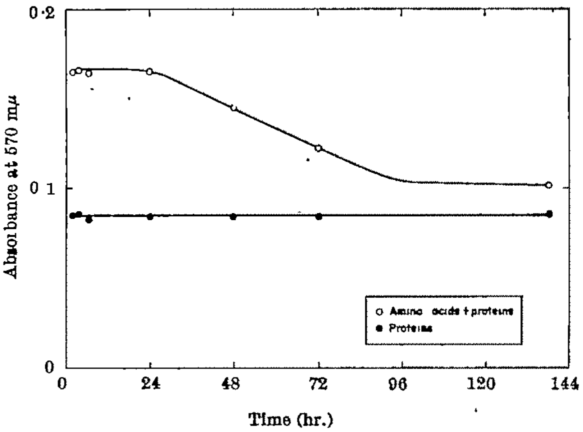

Fig. 1. Relationship between time and colour density of ninhydrin reaction products of amino-acids and proteins in tomato root sections

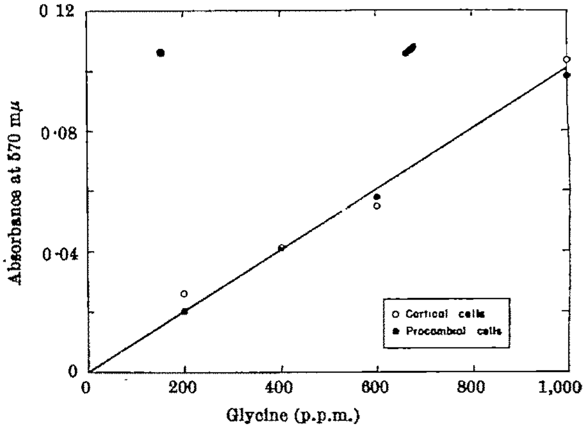

Fig. 2. Relationship between colour density of the ninhydrin reaction product and the concentration of glycine in the solution added to tomato root sections. Infiltrating, fixing and reaction procedures are described in the text

Since tissue sections contain a mixture of amino-acids in different proportions, and ninhydrin products with different extinction coefficients at 570 mμ, standards cannot be calculated directly to determine actual amounts in the cells. However, protein and amino-acid concentrations in different cells and tissues within the same section can be compared.

PATHOLOGY

Precipitating Antibody in Trypanosomiasis of Cattle and Other Animals

PRECIPITATING antibody has been demonstrated in sera from animals which have been infected with trypanosomes, or given a course of injections of material of trypanosome origin, by means of a modified technique of double diffusion in agar gel[1].

Plates were prepared to a depth of 3–4 mm. from 1 per cent New Zealand agar in 0·85 per cent saline containing 0·02 per cent sodium azide, and wells 6 mm. in diameter were cut and lined with a thin film of agar. The distance between centres of adjacent wells was varied from 9 to 11 mm. to suit the system being investigated. Plates were left on the bench at room temperature (20–28° C.) and the wells were refilled at 24 hr. if necessary. Precipitation was usually present at 24 hr. and maximum in 4 days.

Antigens have been prepared from *Trypanosoma vivax*, *T. brucei* and *T. gambiense*. Trypanosomes were separated by centrifugation from citrated blood

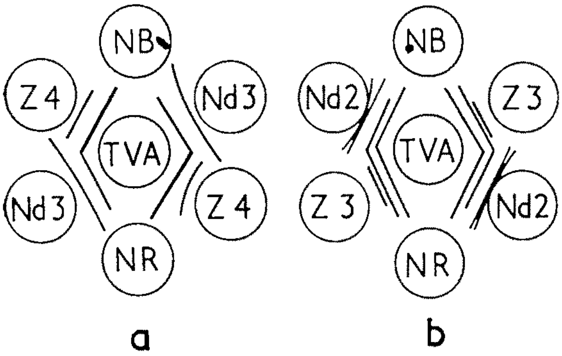

Fig. 1. Examples of precipitation patterns obtained at 24 hr. with *T. vivax* antigen reacting with sera from infected animals and normal (uninfected) controls. *a*, *T. vivax* antigen (*TVA*) against sera from an infected N'dama (*Nd.* 3), an infected Zebu (*Z*.4), a normal bovine (*NB*) and a normal rat (*NR*). *b*, The same antigen reacting with sera from two other infected animals, an old re-challenged N'dama (*Nd*.2) and a Zebu with a chronic *T. vivax* infection (*Z*.3); the same controls as above are also included

of rats showing massive infections. All traces of rat serum were removed by repeated washing with 0·85 per cent saline. Two volumes of saline were added to one volume of packed, serum-free trypanosomes and the suspension was shaken for 30 min. with glass ballotini (No. 12) in a Mickle disintegrator. The cellular debris in the homogenate thus obtained was deposited by centrifugation and the concentrated, opalescent supernatant used as antigen. A satisfactory antigen from trypanosomes of the *congolense* group has not yet been successfully prepared.

Serum samples from infected Zebu and N'dama cattle have given positive reactions; sera from uninfected cattle have been consistently negative.

The period between the beginning of a parasitæmia and the appearance of precipitating antibody to *T. vivax* antigen has been determined in four instances. Two calves, a Zebu (*Z*.1) and an N'dama (*Nd*.1) when first infected by *Glossina morsitans* carrying a mixed infection of *T. vivax* and *T. congolense*, showed precipitating antibody 25 and 39 days respectively after trypanosomes appeared in the blood. Serum from a Zebu bull (*Z*.2) which was exposed to the same challenge contained antibody after 21 days of parasitæmia. An old N'dama bull (*Nd*.2) which had not been exposed to infection for a period of 2 years and showed no chronic infection was rechallenged; antibody appeared after 11 days of parasitæmia.

After treatment of the infections with ethidium bromide, antibody disappeared from the serum of the calves *Z*.1 and *Nd*.1 in 28 days. Precipitating antibody may persist in the serum of an infected, untreated animal even when no trypanosomes can be found in the peripheral blood. The serum of a Zebu bull (*Z*.3) which showed clinical signs of trypanosomiasis in the form of emaciation, enlarged superficial lymph nodes and anæmia, consistently gave a strong reaction with *T. vivax* antigen over a period of 8 months. *T. vivax* has been detected in the blood of this animal in only seven of the wet films examined daily throughout this period. The sporadic parasitæmia, persistence of antibody and the observed clinical signs correspond closely with the findings of Fiennes[2] in cryptic trypanosome infections.

Great variation in the pattern of precipitation occurs in the reactions of sera from individual cattle with antigen obtained from a single source. Fig. 1*a* illustrates the reaction between sera from a Zebu (*Z*.4) and an N'dama (*Nd*.3) and *T. vivax* antigen. Both animals have been repeatedly exposed to tsetse flies carrying a mixed trypanosome infection at intervals during a period of 2 years and are still suffering from trypanosomiasis. They have been treated several times with ethidium bromide when dangerously ill. Fig. 1*b* illustrates the reaction between the same antigen and the serum of the re-challenged N'dama (*Nd*.2) which now has a *T. congolense* infection and the serum of the Zebu (*Z*.3) which has a pure chronic *T. vivax* infection. The differences shown may be due either to the species of infecting organism or to the previous history of the animals or to breed peculiarities.

Antibodies in the serum of an animal with a pure infection have been shown to react with antigenic material from several species of trypanosome. In these cross-reactions the lines of precipitation are characteristically reduced in number, less distinctly defined, and may take longer to reach maximum development.

Serum samples from experimental rabbits, a horse and a duiker have also given positive results after pre-infection samples were negative. Precipitating antibody has been detected by this method in three out of five cases of human sleeping sickness caused by *T. gambiense*. This work is being continued and extended.

I am grateful to several of the senior staff of this Institute for their help: to Dr. K. C. Willett for his constructive criticism, to Drs. J. Williamson and R. S. Desowitz for technical advice and encouragement and to Dr. L. E. Stephen for sera from several of his experimental animals.

Non-Protein Sulphydryl Group in the Original Strain and Sub-line of the Ascites Tumour resistant to Alkylating Reagents

I HAVE succeeded in establishing resistant variants of the Yoshida ascites sarcoma and ascites hepatoma (*AH* 13 and *AH* 7974) to methyl-*bis*-(β-chlorethyl)-amine N-oxide, one of the alkylating agents, by passing tumour cells through animals treated with the reagents[1]. These resistant variants were proved to be cross-resistant to the other alkylating reagents, but not cross-resistant to the unrelated reagents[2]. Furthermore, no difference could be detected in cytological features of tumour cells between the original and resistant sub-lines. Details concerning the biological properties of these resistant sub-lines are to be found in previous papers[1–3]. The mechanism of development of resistance to this reagent is not yet clear. However, it is well known that nitrogen mustard inactivates sulphydryl groups. Also a preferential affinity of methyl-*bis*-(β-chlorethyl)-amine N-oxide to sulphydryl groups has already been reported by Torigoe[4] and Ishidate[5]. From this point of view, I attempted to study the non-protein

Table 1. CONTENT OF NON-PROTEIN SULPHYDRYL GROUP IN THE ORIGINAL STRAIN AND RESISTANT SUB-LINE OF THE YOSHIDA ASCITES SARCOMA AND ASCITES HEPATOMA

	μM per gm. based on wet weight*		
	Yoshida ascites sarcoma Mean ± *S.E.*	Ascites hepatoma *AH* 13 Mean ± *S.E.*	Ascites hepatoma *AH* 7974 Mean ± *S.E.*
Original strain	2·54 ± 0·27	3·11 ± 0·31	3·96 ± 0·48
Resistant sub-line	5·71 ± 0·48	5·31 ± 0·30	5·53 ± 0·32
Probability	$P < 0{\cdot}001$	$P < 0{\cdot}001$	$P < 0{\cdot}01$

* Each value indicates average of nine rats.

sulphydryl content of tumour cells in the original strain and resistant sub-line.

In this work, the Yoshida ascites sarcoma, *AH* 13, *AH* 7974, and their resistant sub-lines were used. All these resistant sub-lines were successfully transmitted in the absence of the reagent. A total of 54 rats of mixed breed and weighing about 130 gm. were used, each receiving an intraperitoneal inoculation of 0·5 c.c. of undiluted tumour ascites in the state of nearly pure culture, that is, the tumour cells of each original strain or resistant sub-line were inoculated into nine rats respectively. They were highly susceptible to these tumours. The tumour ascites were withdrawn from the peritoneal cavity when the state of nearly pure culture after inoculation with the tumour was reached, washed immediately with saline, and centrifuged for 3 min. at 3,500 rev./min. Tumour cells thus obtained were weighed, and with the use of about 500 mgm. of tumour cells in wet weight, non-protein sulphydryl group was determined according to the amperometric method described by Weissman *et al.*[6] and Goldzieher *et al.*[7].

Results are shown in Table 1. A difference of mean value between each original strain and its resistant sub-line was tested statistically. The average content of non-protein sulphydryl in the original strain of the Yoshida ascites sarcoma was 2·54 μmoles/gm. and that in the resistant sub-line was 5·71 μmoles/gm.; that is, the average content in the resistant sub-line was more than twice that in the original strain. Furthermore, also in the ascites hepatoma, *AH* 13 and *AH* 7974, the average content of non-protein sulphydryl in the resistant sub-line was found to be increased as compared with that in the corresponding original strain. The difference between the original strain and its resistant sub-line in both *AH* 13 and *AH* 7974 was statistically significant (Table 1). From these results it is evident that the sub-line resistant to methyl-*bis*-(β-chlorethyl)-amine N-oxide, which was established by passing tumour cells through animals treated with the reagents, showed a significant increase in non-protein sulphydryl content as compared with the original strain, whether the Yoshida ascites sarcoma or ascites hepatoma.

Since alkylating reagents show an affinity for sulphydryl groups, it seems to be most probable that tumour cells containing a large amount of non-protein sulphydryl group are more endurable, owing to counteracting the action of the reagents, than those containing a smaller amount. As a matter of course, many factors might be related to the mechanism of resistance to alkylating reagents. However, it is considered that the non-protein sulphydryl group of tumour cells plays an important part in the mechanism of resistance to alkylating reagents, at least in that of induced resistance as revealed in this work.

I wish to express my thanks to Prof. T. Yoshida for supplying the tumour strains and for his encouragement in many ways, and to Dr. Y. Sakurai and Dr. K. Kaziwara for supplying methyl-*bis*-(β-chlorethyl)-amine N-oxide. I am also indebted to the Department of Bacteriology, Nagoya University, for providing laboratory facilities.

The work was aided by a grant from the Japanese Cancer Society.

Enhanced Resistance of Mice to Infection with *Pasteurella pestis* following Vaccination with Fractions of Phenol-killed Tubercle Bacilli

THE growing recognition that the immunological responses initiated by certain micro-organisms are not necessarily limited in their scope, but may be manifested towards taxonomically and antigenically heterologous organisms[1], raises the question of whether many states of specifically acquired immunity rest entirely on specific mechanisms. The increased resistance which accrues to survivors of a first infection, or which follows a specific immunization procedure, may not always be based on specific immunological reactions, that is, those involving antibody or tissue hypersensitivity, but may result from the same non-specific effects which underlie the development of heterologously orientated changes in immunity.

This may be true not only of diseases immunity to which has never been proved to be associated with a classical immune response, but also of those where heightened resistance is accompanied predictably by the formation of antibody: the antibody response may be incidental to, not causative of, the acquisition of the immunity. An analysis of the area and mechanisms of the non-specific immunological abilities of a micro-organism may therefore contribute as well to an understanding of its homologously directed activity.

Such a comparative approach to the problem of the mode of action of specifically acquired immunities requires a determination of whether the microbial moieties responsible for the homologous effects are the same as, or distinct from, those exerting an immunological influence of wider implication. In the course of a study of the mechanisms of acquired resistance to tuberculosis, an investigation was accordingly undertaken to ascertain whether fractions of the tubercle bacillus which show homologous immunogenicity are related to those reported to affect resistance to other diseases[2,3].

Table 1

Vaccine	No. of animals per group	Deaths* on following days after *Pasteurella* infection: 4	5	6	7	8	9	12	13	14	15	No of survivors†
Methanol extract, in saline	10	0	0	0	2	0	0	4	0	0	0	4 of 10
Methanol extract, in adjuvant	13	0	0	0	1	0	1	0	0	0	1	10 of 13
Saline (control)	18	0	3	4	6	2	1	1	0	0	0	1 of 18

* All animals dying after infection were found to have extensive lesions of the spleen, liver and mesenteric nodes.

† All animals surviving past the fifteenth day appeared normal; experiment terminated on twentieth day.

Initial experiments were designed to establish the range of experimental infections of laboratory animals which could be influenced by previous vaccination with components of chemically killed tubercle bacilli. Early in the course of this investigation it was found that certain crude fractions which have been shown capable of enhancing the resistance of mice and guinea pigs to tuberculous infection[4,5] bestow a marked degree of heightened resistance on mice against infection with a strain of *P. pestis*, *EV* 76[6,7]. Also of interest was the observation that, unlike many of the hitherto reported instances of non-specific resistance to infections, this immunity was still discernible even when the experimental *Pasteurella* infection occurred some weeks or months after vaccination with tubercle bacillus substances. This communication reports on two experiments illustrating these findings.

Experiment 1. Groups of Swiss albino mice (Rockefeller strain) were injected intraperitoneally with 1·0 mgm. quantities of a crude methanol-soluble extract of phenolized bacilli of the *B.C.G.* strain[5], suspended in saline or in incomplete Freund's adjuvant. Two months later, these animals, and a saline-injected control group, were given an intraperitoneal injection of 1 × 10⁷ living organisms of the *EV* 76 strain of *P. pestis*. The post-infection survival time of the animals is shown in Table 1.

Experiment 2. Groups of mice received intraperitoneal injections of one of the following, in 0·5 c.c. quantities: distilled water; a young 'Tween'-albumin culture of the *B.C.G.*-Phipps strain; 1·0 mgm. of the bacterial residue of a methanol extraction of phenolized *B.C.G.* organisms. Three weeks later, the animals were challenged by the intraperitoneal route with 3 × 10⁷ organisms of the *Pasteurella* strain. The post-infection survival-time of the animals is shown in Table 2.

The lower degree of survival protection bestowed by living *B.C.G.* and extraction residue does not necessarily indicate their inferiority *vis-à-vis* methanol extract in initiating this non-specific immunity, but might be accounted for by the larger challenge dose, or by the shorter vaccination-challenge interval, in the second experiment.

Table 2

Vaccine	No. of animals per group	Deaths* on following days after *Pasteurella* infection: 3	4	5	6	7	8	11	12	13	14	15	No. of survivors†
Extraction residue	23	0	4	3	3	2	0	1	1	2	0	0	7 of 23
Living *B.C.G.*	21	0	8	2	3	1	0	1	2	0	0	0	4 of 21
Distilled water (control)	22	0	19	0	1	0	0	0	0	0	0	0	2 of 22

* All animals dying after infection were found to have extensive lesions of the spleen, liver and mesenteric nodes.

† All animals surviving beyond the fifteenth day appeared normal; experiment terminated on twentieth day.

More extensive experiments on the extent and conditions of the effects of substances derived from tubercle bacilli on the resistance of laboratory animals to other infections, and to tumour transplants, are now in progress, and will be reported in detail elsewhere.

I wish to acknowledge the help of Mr. Salvatore Margherita in certain phases of this work.

[6] It has been reported previously that tuberculous and leprous diseases confer resistance on man and on laboratory animals against plague infection (Girard, G., and Grumbach, F., *C.R. Soc. Biol., Paris*, 152, 280 (1958); Rep. Internat. Plague Conf., Mukden, 1911).

[7] The *EV* 76 strain of *P. pestis* is relatively avirulent (Walker, D. L., *et al.*, *J. Immunol.*, 70, 245 (1953)), but kills mice when given in large numbers.

Zinc Sulphate Treatment of Parakeratosis in Cattle

UNDERWOOD[1], discussing the nutritional significance of trace elements, states "zinc deficiency has never been observed in man or in farm stock, under either naturally occurring or experimental conditions. It seems very unlikely that such a deficiency could ever arise in grazing or stall fed sheep or cattle, because of the normal high content of zinc in plant materials". Symptoms indicating zinc deficiency conditioned by high dietary calcium have, however, been reported in pigs.

During the period 1957–59 we have observed, in cattle on the Berbice savannahs, lesions closely resembling those described in rats fed on diets deficient in zinc. In the more acute cases, parakeratosis spreads rapidly over about 40 per cent of the body surface. The following areas are affected, usually in the order given: muzzle (except when this is black in colour), vulva, anus, top of tail, ears, back of hind limbs, 'knee fold', flanks and neck. On this Station, these symptoms have occurred seasonally, namely, March–June; during this period in 1958 there were about six cases, and in 1959 upwards of twenty among 1,000 cattle. The over-all body condition of cows affected has been generally below average; yearlings have shown little or no live-weight gains for some months whereas very young calves have been otherwise normal. The stock affected, other than the young calves, have been born and reared under range conditions; the soils are poor and sandy. Some of the yearlings had been transferred to planted, fertilized pastures of pangola grass (*Digitaria decumbens*), 2–4 weeks before symptoms were observed.

During April and May 1959 some affected animals have been given zinc sulphate either orally (2 gm./

week) or by injection (1 gm./week); similar animals kept as controls have been treated later. The skin of two cows and four yearlings treated early showed new hair growth one week after treatment commenced, and were normal after three weeks, while three cows and one yearling untreated for periods ranging from 2 to 8 weeks deteriorated during this period, but again, after treatment, recovery was rapid. In one yearling which finally became weak and had to be destroyed, the skin condition responded to zinc administration. On June 23, one cow with a newly born calf and seven in-calf cows were removed from Range 2, where most cases had occurred, to pangola grass pastures. This calf and four others born to the cows during June all shed the bulk of the hair from large areas of the body; this was accompanied by hyperkeratinization along the mid line of the back. The hair and skin rapidly returned to normal after oral administration of zinc sulphate. The dams of these calves showed no lesions nor were there any cases among other calves born on these pastures during the same period. Two of the cows moved from the Range on June 23 calved during July and August; one had quite normal hair and skin and the other only very slight parakeratosis.

In pot trials on these soils in which the plant grown had been the tomato, growth responses have been obtained from the application of zinc (Spector, J., private communication). The zinc content of various grass species is given in Table 1. The plant material, collected after the first cases of parakeratosis were observed, consisted of leaf cut about 1 in. above ground-level.

Table 1. Zinc Content of Grass Samples collected at Ebini, 1959

Date collected	Description of pasture	Species	Zinc content (p.p.m. of D.M.)
May 14	Fertilized pasture No. 15	Pangola (*Digitaria decumbens*)	34
June 11	,,	,,	42
June 27	,,	,,	42
June 13	Fertilized pasture No. 16	,,	30
June 27	,,	,,	38
May 16	Range 2	*Trachypogon polymorphus*	22
June 26	,,	,,	18
June 28	Range 12	,,	20
May 15	Range 2	*Axonopus strogalus*	26
June 26	,,	,,	28
June 28	Range 12	,,	36

Radiochemical balance studies indicate that the absorption of zinc from the alimentary tract in steers is not greater than 50 per cent[3]. These absorption studies and the low zinc content of the fibrous *Trachypogon* indicate that cattle in these conditions may not always receive adequate zinc in the diet. Our observations add support to this view.

We are indebted to the Director of Agriculture, Georgetown, for the facilities for making these observations and to Dr. H. Evans of Bookers Sugar Estates, Ltd., for carrying out the zinc assays.

RADIOBIOLOGY

The Sigmoid Survival Curve in Radiobiology

A strictly exponential form of survival curve is much more rarely encountered in radiobiology than might be supposed from statements sometimes made. The form of survival curve illustrated by Fig. 1 (which would be sigmoid on a linear plot) has been established, with varying degrees of accuracy, for many single-cell populations, ranging from bacteria to mammalian cells.

It has become common practice to describe such curves as 'multihit' or 'multiple-target' curves; and to regard the existence of the initial shoulder as inevitably implying the existence of a 'multiplicity' or 'target-number' or 'hit-number' of discrete morphological sites or entities, the number of which may be determined by extrapolating the exponential portion of the curve back to zero dose and measuring the intercept on the ordinate plotted on a logarithmic scale. While it is useful to have a name for the number so derived, we consider that those commonly used carry an unjustifiable implication as to the mechanism of radiation damage to cells. This has become particularly undesirable in view of recent work which has shown that this number may in some cases depend, over a wide range, on conditions imposed after irradiation[1-3]. Conditions before irradiation have long been known to produce such changes in survival curves[4], and it may be that in such cases the change in 'multiplicity' of the survival curve corresponds to a real morphological change in the cell. But when cells irradiated as one population demonstrate survival curves with different 'multiplicities', depending on how they are treated after irradiation, the concept that such curves imply a multiple number of discrete morphological sites becomes very strained.

We propose, therefore, in our future publications to use the term 'extrapolation number' to refer to the intercept e, or the ratio e', shown in Fig. 1. We do

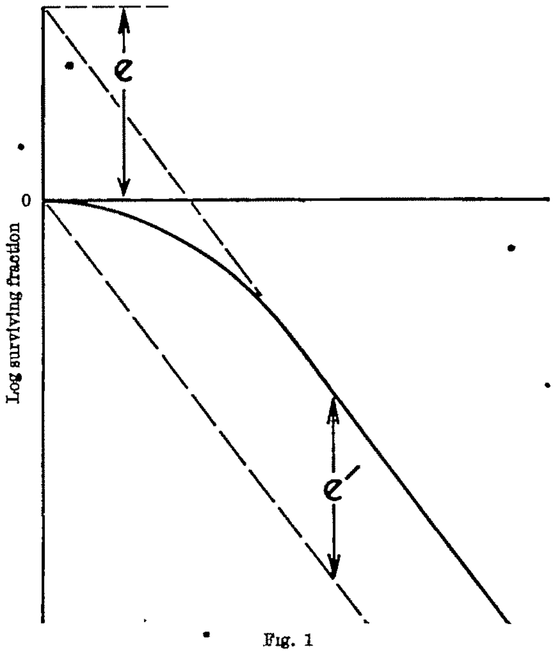

Fig. 1

not abandon the postulate that this number may refer to a multiplicity of some sort, and we concede that in some instances it may be identifiable with a number of specific morphological entities[5]; but we would suggest that the number in question should be referred to as a 'target' or 'hit' number only when such identification can be made.

An Assessment of the Quantities of Fission Products likely to be found in Milk in the Event of Aerial Contamination of Agricultural Land

THERE is considerable evidence that the most widespread hazard which could result from the deposition of fission products on agricultural land would be the contamination of milk with the isotopes of iodine and strontium[1]: other fission products which might in certain circumstances contribute to this hazard are barium-140 and cæsium-137.

In the initial period after the release of fission products the first information on the extent of deposition which is likely to be available will be the results of gamma monitoring, from which the deposition per unit area of land can be estimated on the basis of an assumed composition of the released material. It is therefore of considerable practical importance to consider the relationships which may occur between the quantity of radioactivity deposited per unit area after a single incident and the level in the milk.

The transfer of certain fission products from the diet of cows to their milk has been studied experimentally in this laboratory: results are now available from 28 experiments with iodine-131 on 20 animals, 16 experiments with strontium-89 on 12 animals, 5 experiments with barium-140 on 5 animals, and 4 experiments with tellurium-132 on 3 animals. Preliminary accounts of part of this work have been given[2,3] and detailed reports will be published elsewhere. Studies with cæsium-137 have not been made, but results from experiments on 5 animals are available in the literature[4].

Under field conditions the extent to which fission products deposited upon grazing land will enter milk may vary greatly depending upon many factors including: (1) the extent to which the deposited material is initially retained on edible herbage; (2) the extent to which the initially contaminated herbage is 'diluted' with new growth; (3) the extent to which the fission products are removed by rain from the edible tissues; (4) the method of animal management.

In order to make some estimate from the experimental data of the maximum level of contamination in milk likely to be encountered in the field, the following conditions have been assumed: (*a*) that 25 per cent of the deposited material is initially retained on edible herbage; (*b*) that the activity on herbage decreases only as a result of the decay of radioactivity; (*c*) that animals have unrestricted access to grazing and receive no supplementary food; (*d*) that animals consume 20 lb. dry matter a day and that the yield of edible herbage is 500 lb. dry matter per acre. Estimated values for levels in milk following continuous grazing for 21 days when the initial total deposition of individual fission products from a single incident is 1 $\mu c./m.^2$ are given in Table 1.

The assumptions made are considered to represent the worst case likely to occur under conditions of British agriculture. There are many factors which, in normal circumstances, would probably reduce the quantity of fission products transferred to milk. Thus the combined effect of the growth of new grass and the removal of activity from edible herbage by rain should normally cause the extent of contamination of herbage, and hence the contamination of milk, to fall considerably more rapidly than is suggested in Table 1. Further, should an accident occur at a time when grazing is poor, derivation of most of the food from uncontaminated supplementary feeding-stuffs would considerably reduce the animals' intake of fission products. However, mitigating factors of this kind cannot be predicted, and hence no allowances can be made for them in the early stages after an accident. The figures given are therefore put forward as being of value in the preliminary planning of control measures following the release of radioactivity: any steps to be taken thereafter must be based upon measurements made upon the milk itself.

Table 1. ESTIMATED ACTIVITY IN MILK ($\mu c./l.$) FOLLOWING AN INITIAL TOTAL DEPOSITION OF 1 $\mu c./m.^2$

Inability of Methionine to affect Lethality in Mice and Rats exposed to X-Rays

NERURKAR *et al.*[1] have shown that administration of methionine either before or after X-irradiation decreases the damage caused to nucleic acid synthesis in irradiated rats. Post-irradiation administration of methionine appears to be more effective. Other assays have shown a lower increase in nitrogen, uric acid and in creatinine excretion in irradiated rats injected with methionine after irradiation[2]. The increase in uric acid excretion suggests excessive breakdown of nucleic acids as a result of cellular destruction. Treatment with methionine also results in a beneficial influence on the rate of growth after irradiation.

The present communication shows that the administration of methionine, apparently effective in slowing down the fall in nucleic acid levels caused by a single exposure to ionizing radiations, affords no decrease in the mortality of mice (*C*57 black) and rats (Wistar albino) irradiated with 700 or 800 r. of X-rays.

220 male black *C*57 mice, weighing 20–25 gm., were divided into eight groups. Each irradiated group consisted of fifteen controls injected intraperitoneally with 0·9 per cent sodium chloride and fifteen animals injected intraperitoneally with an aqueous solution of L-methionine (Sigma) (5 mgm., 25 mgm., and 250 mgm./kgm.) 5 min. before or 30 min. after irradiation respectively. One irradiated group received one injection 30 min. after irradiation and two daily injections of methionine (5 mgm./kgm.) during the five days following irradiation. A control group, injected with methionine (250 mgm./kgm.), was not irradiated.

Table 1. EFFECT OF INTRAPERITONEAL INJECTION OF L-METHIONINE BEFORE AND AFTER TOTAL-BODY X-IRRADIATION OF 700 R. ON MORTALITY MOUSE BLACK *C*57 STRAIN.
kV., 200; m.amp., 20; d.f., 42 cm., 0·5 copper; dosage-rate, 84 r./min. in air

Dose of L-methionine	No. of animals	Total mortality at 15 days (per cent)	Average time of survival (in days) ± *S.D.*
Methionine 5 min before 700 r.			
Controls	15	100	8 00(±2 17)
5 mgm./kgm.	15	100	8 33(±2 16)
Controls	15	100	8 93(±1·39)
25 mgm./kgm.	15	100	10 06(±1 58)
Controls	15	100	9·33(±2·41)
250 mgm /kgm.	15	100	8 60(±2 29)
Methionine 30 min. after 700 r			
Controls	15	100	7 60(±3 34)
5 mgm./kgm.	15	100	6·80(±1·22)
Controls	15	100	8 06(±1 87)
25 mgm./kgm.	15	100	7 20(±2 78)
Controls	15	100	7·69(±2 23)
250 mgm./kgm.	15	100	8 06(±2 52)
Chronic treatment			
Controls	15	100	8 40(±1 88)
5 mgm./kgm. × 11	15	100	7·13(±1 60)

Methionine does not significantly affect the mortality after irradiation ($P < 0\ 01$).

Table 2. EFFECT OF INTRAPERITONEAL INJECTION OF METHIONINE (5 MGM./KGM.) AFTER A SINGLE TOTAL-BODY X-IRRADIATION OF 800 R. ON MORTALITY MALE WISTAR ALBINO RATS.
(kV., 200; m.amp., 20, d.f., 55 cm., 0 5 copper; dose-rate, 50 r./min. in air

Dose of methionine	No. of animals	Total mortality at 30 days (per cent)	Average time of survival (in days) ± *S.D.*
Controls	30	96·6	8·16(±4·70)
5 mgm./kgm.	30	100	8 96(±4·55)

Methionine does not affect significantly the mortality after irradiation ($P < 0\ 01$).

Sixty male Wistar rats, weighing 175–225 gm., were divided into two groups of thirty animals each. The first group served as control and received an intraperitoneal injection of 0·9 per cent sodium chloride; the second group, an injection of L-methionine 30 min. after a total-body X-irradiation of 800 r.

Physical factors of irradiation are given in Tables 1 and 2. All the mice irradiated with 700 r. and 96 per cent of rats irradiated with 800 r. died between the fourth and fifteenth days after irradiation. The same mortality was observed in the groups treated with methionine before or after irradiation (Tables 1 and 2). L-Methionine is not toxic, at the above-mentioned doses, to our mice or rats. In previous investigations, Bacq *et al.*[3] have observed that methionine does not protect mice against X-irradiation. The present results confirm these findings.

According to Nerurkar *et al.*[1,4] there is after irradiation a lack of available methionine, and the injection of methionine should help the restoration of the nucleic acid-synthesizing mechanism. But, in our opinion, this effect of methionine is not sufficiently important to affect the mortality.

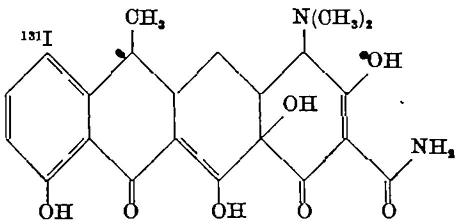
Radioactive 7-Iodo-6-Deoxytetracycline in Tumour Tissue

THE observation[1,2] that several of the tetracyclines are localized in various tumour tissues for prolonged periods of time suggested the possible utility of a tetracycline labelled with iodine-131 in the detection of neoplastic disease by the use of external body-scanning techniques. In a recent communication[3] from this Laboratory, the preparation of 7-iodo-6-deoxytetracycline was described; this was the first report of an iodotetracycline of unequivocal chemical structure. A labelled iodo (131) derivative was prepared by essentially the same method, by the reaction of N-iodosuccinimide[4] (^{131}I) and 6-deoxytetracycline in concentrated sulphuric acid:



The radioactive preparation was administered intravenously at a dose of 15 mgm./kgm. to dogs that had well-developed, spontaneous mammary tumours. The level of radioactivity at marked areas on selected portions of the dog was then determined at various intervals of time.

Some of these results are shown in Fig. 1. It can be seen that in the first three hours there is a pronounced difference in the degree of radioactivity in the areas of the various organs and tissues. The area over the liver gave the highest reading, followed by the tumour and kidney. The muscle and skeletal readings were considerably lower than that of the tumour tissue.

The differences in the radioactivity after 24 hr. were much less pronounced, and some considerable changes appeared in the relative ranking of the various areas measured.

There appeared to be no preferential retention of radioactivity in the tumour during a period of 24 hr.–6 days, but some small preferential retention was noted in the thyroid region. Although it has been shown that some of the other tetracyclines are not metabolized by animals[5], it is possible that de-iodination *in vivo* may have occurred to some small extent, and any iodide liberated would be taken up by the thyroid.

Other areas surveyed, but not shown in Fig. 1, include the occipital bone, last sacral, mid-shoulder back, knees and thyroid. During the first three hours, the level of radioactivity for these locations was generally less than that of the thigh muscle.

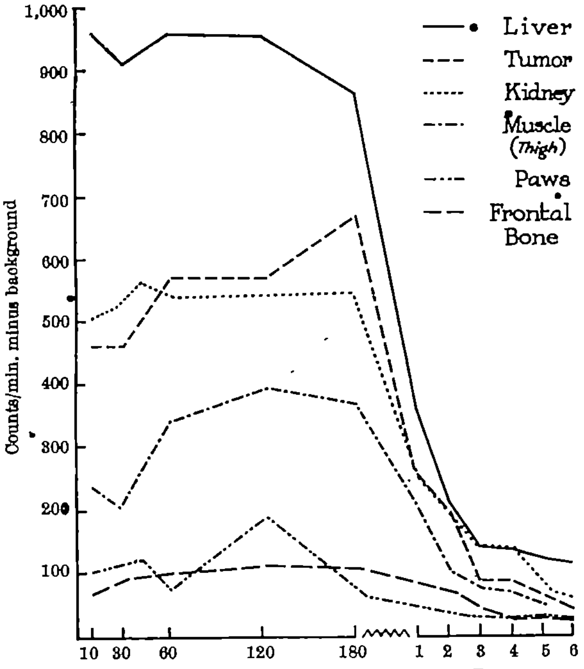


Fig. 1

Direct radiometric readings were made on various tissues removed from a dog (with a mammary tumour) 10 min. after an intravenous administration of the radiolabelled compound. As was expected in this short period, the liver, kidney, spleen and blood contained the highest levels of radioactivity. However, the tumour contained three or four times the counts per minute per milligram of muscle or bone. Healthy tissue, adjacent to and more highly vascularized than that of the tumour, contained only one-half of the radioactivity, on a counts per mm./mgm. basis, of the tumour. The iodotetracycline has also been studied in mice containing spontaneous mammary tumours, but no pronounced selective localization or retention was found with this type of tumour.

Although the biological work with this compound is in an early development stage, it appears that the differential localization of 7-iodo-6-deoxytetracycline in tumour tissue, relative to that of other tissue, may be sufficient to allow the use of this compound as a diagnostic aid in the location of cancerous growths.

A therapeutic application by the internal irradiation of selected tissues, either with a tetracycline derivative containing a pre-formed radioisotope, or by the induction of irradiation by a procedure such as neutron activation, is a possibility but will require much additional work.

We thank Dr. J. H. Boothe, Dr. A. W. Vogel and Dr. S. Kushner for their helpful suggestions, and Mr. D. Colucci for technical assistance.

BIOLOGY

Dependence of the Sex Ratio at Birth on the Age of the Father

SZILARD's conjecture about the effect of paternal age on the sex ratio, which his figures for man support[1], might perhaps be capable of further confirmation in horses. Unlike the ages of man and wife, those of mare and stallion are uncorrelated, and both are commonly bred into old age. I investigated the effects of paternal age on foal longevity[2], which is also germane to Szilard's theory, and found no appreciable decline in the vigour of the fillies of old stallions, judged by life-spans in the "General Stud Book"—no records of colt longevity are available. My material gives some figures for the sex ratio, though the numbers are too small to do more than suggest the absence of any gross age effect. The ratio of males to females was exactly 100·00 for the

446 live progeny born during 1885–96 of a group of stallions known to be more than twenty years old at covering, against 100·47 for all foals in the same period. Masculinity in thoroughbred horses is less than in man, and the ratio has been reasonably stable for a century or more (1853–68 $R = 100 \cdot 32$; 1869–80 $R = 99 \cdot 18$; 1885–96 $R = 100 \cdot 47$; 1925–40 $R = 99 \cdot 31$).

We may attempt to predict the expected change in R for thoroughbreds if Szilard's assumptions hold good. Their last decile survival is reached at about 30 years against 90 in man, but the proportionate 'weight' of the Y chromosome will be less, since for horses $2n = 66$, say 1·4 per cent. Other things being equal the change in the value of R would therefore be about 2·8 per decade, approaching $R = 106$ per cent for stallions more than twenty years of age. A difference of this order could probably be detected from siring records, and this appears worth attempting in spite of the number and variety of the other numerical assumptions which Szilard's theory requires.

Purification of a Specific Inducer of the Male Sex Organ in Certain Fern Species

A NATURALLY occurring, highly specific substance has been found which induces vegetative cells of gametophytes of certain fern species to differentiate and organize the male sex organ or antheridium. Döpp[1] showed that a water extract of mature prothalli of the common bracken fern *Pteridium aquilinum* hastened the formation of antheridia in young prothalli of this and of another fern species. He was inclined to interpret his findings to indicate that antheridia were initiated by way of non-specific growth inhibition. Naf[2] reported that the promotion of antheridium formation by the extract was due to a specific antheridium-inducing factor rather than to non-specific growth inhibition. The biologically active factor was found to induce antheridium formation in representatives of 7 of the 9 sub-groups of the family Polypodiaceae listed by Eames[3] as well as in *Dennstaedtia punctilobula*, a member of the family Dicksoniaceae[4]. It appeared likely, therefore, that a relatively simple chemical substance is capable of directing morphogenesis in a highly specific way. In view of its unique properties, an attempt was made to isolate and characterize chemically the biologically active material. The present report describes a procedure for the purification of this substance.

Quantities of antheridium-inducing factor for chemical isolation were obtained batchwise by seeding 1,000 125-ml. Erlenmeyer flasks containing 33 ml. of Moore's synthetic medium with sterile spores of *Pteridium aquilinum*. The cultures were grown under continuous illumination for a period of 7 weeks. Using this procedure, about 30 l. of culture filtrate with a dilution end-point of about 1 : 10,000 were obtained from most batches.

The progress of the isolation of the biologically active substance was followed using young gametophytes of the sensitive fern *Onoclea sensibilis* as the test object according to the assay method described by Näf[2]. Prothalli of this species failed to form antheridia spontaneously under the conditions of culture employed, but produced numerous antheridia after exposure to the biologically active factor. This made it possible to test with certainty the antheridium-inducing activity of any preparation.

The 30 l. of culture filtrate used as starting material for each isolation contained about 1 mgm. of solids per ml. This solution was concentrated *in vacuo* in a circulating evaporator, below 45° C., to a volume of 1 litre and stirred at room temperature for 1 hr. under nitrogen with 10 gm. of 'Norite *A*' which had been boiled with dilute acetic acid and washed with boiling water. This treatment removed more than 99 per cent of the activity from the concentrated culture filtrate. The charcoal was removed by filtration, washed twice with 500 ml. of water, and the washings discarded. The active material was eluted from the charcoal by stirring for 15 min. with 100 ml. of methanol. No more activity was removed after three such treatments. 10 µgm. of material obtained in this way induced antheridium formation at a maximum dilution of 1 : 4,000, representing a fortyfold increase in activity over the original culture filtrate.

The combined methanol eluates were concentrated *in vacuo* to remove methanol and made up to a volume of 50 ml. with ice-cold 0·01 M phosphate–citrate buffer adjusted to pH 7·2. This solution was extracted three times with cold ethyl acetate, removing inert material amounting to about 40 per cent of the dry weight of the methanol eluate. The pH of the cold buffer solution was lowered to 5·1 with hydrochloric acid, and the active material was removed by extracting three times with ethyl acetate. This fraction contained about 20 per cent of the dry weight of the methanol eluate and all the antheridium-inducing activity. 10 µgm. induced antheridium formation at a maximum dilution of 1 : 20,000, representing two-hundredfold increase in activity over the original culture filtrate. An average yield of 3 mgm. was obtained from 30 l. of culture filtrate.

Final purification was made by concentrating the ethyl acetate extracts to a small volume and subjecting the material to a 50-tube counter-current distribution between normal butanol and 5 per cent ammonium acetate buffer pH 6·65. Almost all the activity was distributed as a single peak with a maximum in tube 23. An exact quantitative determination of activity was difficult since more than one-half of the starting weight remained in the first three tubes or migrated completely into the last four or five tubes of the series. A very small amount of activity was also found in the last few tubes. When tubes 19 and 32 of this series were redistributed in the same solvent system, only a single peak of activity was found with a maximum in tube 23, in each case. Thus, the active material purified in this way appeared to be homogeneous. Because of the difficulty of weighing the tiny quantities obtained, it was not possible to determine the specific activity on a dry-weight basis. However, it was apparent that this purified material would induce antheridium formation in *Onoclea sensibilis* at a concentration of less than 1 part in 10,000,000,000 (10^{-4} µgm. per ml.).

As indicated by the manipulations used in the isolation procedure, the antheridium-inducing factor behaves as a weak acid. It is relatively stable in acid solution, but is readily inactivated at pH above 7. It is also readily inactivated by oxidizing agents, and dry preparations quickly darken and lose activity on exposure to air. The factor is readily soluble in a number of alcohols and esters, slightly soluble in ethers, and relatively insoluble in aliphatic and aromatic hydrocarbons or chlorinated aliphatic hydrocarbons. Activity is strongly adsorbed on activated alumina from alcohol solutions, from which it can be partially eluted by glacial acetic acid. The factor can be chromatographed on filter paper in a variety of alcohol/water solvent systems. Good resolution was obtained in descending chromatography on Whatman filter paper No. 1, using (1 : 4) *iso*propanol/water, where the factor has an $R_F = 0 \cdot 8$.

It is not possible at the present point in this investigation to state that antheridium-inducing factors other than that described here are not present in the culture filtrate or gametophytes of *Pteridium aquilinum*. However, it is clear that a single, homogeneous, relatively simple chemical substance is capable, at extremely low concentration, of directing cellular differentiation and organization. Studies on the chemical constitution of the antheridium-inducing factor described here will be continued.

This work was supported in part by a research grant (NSF Grant No. *G*-6144) from the National Science Foundation.

Manganese Toxicity in *Grevillea robusta*

Grevillea robusta A. Cunn. is commonly grown as a shade tree in East African tea plantations. Seedlings are usually raised in nurseries and transplanted to the field when about 4 in. high. Failure of the plants has been reported when they are transplanted into the red, highly acid soils characteristic of some tea areas, of which the *p*H may be as low as 4·2.

Some such seedlings, which had died within three weeks of transplanting, were sent for examination from a Kericho estate. Two specimens (on the dry-weight of leaf plus stem) contained 1,940 and > 4,000 p.p.m. of manganese respectively, and those of a healthy seedling had 880 p.p.m.

On another estate, *Grevillea* seeds had been nursery planted, some in a red soil (*p*H 4·6) and others in a less-acid soil (*p*H 5·4). Seedlings from the former soon died (dry weight of the aerial portion of the plants about 0·05 gm.), and one specimen had a manganese content of 3,650 p.p.m., while a healthy plant from the less-acid soil had 262 p.p.m. of dry weight.

Local applications of basic slag were recommended when transplanting into acid soil. F. Haworth[1] notes that in Ceylon basket plants of *G. robusta* and *Albizia moluccana* are potted in a soil limed to a *p*H value of between 6·0 and 7·0.

Monoxenic Cultivation of an Enchytræid Annelid

A CULTURE of *Enchytræus fragmentosus* Bell, 1959 [1], was kindly sent us by Prof. A. W. Bell of Los Angeles City College in May 1959. We have been able to grow it without difficulty since that date, on rolled oats kept on moistened filter paper, and can now report success in putting it into monoxenic culture (that is, growing in the presence of a single species of associated organism—in this instance *Escherichia coli*).

A single specimen of *E. fragmentosus* from a xenic culture (that is, growing in the presence of a mixed microbial flora) was transferred to a Petri dish of 'Difco Nutrient Agar' previously seeded with enough *E. coli* to yield a thin continuous bacterial layer. It was allowed to migrate there and, on an average of every other day over a period of a month, was transferred to a fresh Petri dish of agar and *E. coli*. The track of the worm during each stay could be readily seen; it is thus possible to say that, because of its relatively sluggish movement under the conditions described, it seldom looped back over its path. Only after the thirteenth transfer (one month) was it found to have fragmented into several pieces. This long period without fragmentation suggested a nutritionally unfavourable state. Three short pieces were then put on to a single agar slant streaked with *E. coli*, where they grew into long worms within two weeks. A subculture was next made with one worm, followed by additional fragmentation into two.

Repeated bacteriological checks of both slants revealed only *E. coli*. We can therefore conclude that the original worm was effectively monoxenized merely by migrating for an extended period in successive thin layers of *E. coli* growing on nutrient agar.

Subsequent work has shown that nutrient agar with *E. coli* is not satisfactory by itself for indefinite subculture of *E. fragmentosus*. But grains of autoclaved rolled oats dropped on the surface of the slant provide for continued vigorous growth, and the combination so established appears satisfactory for indefinite monoxenic cultivation of the annelid.

More recently we have sometimes found it possible to axenize *E. fragmentosus* directly from xenic culture by a method based on that applied to the planarian *Dugesia dorotocephala* by Miller and Johnson[2]. In one instance, after three days of washing about 40 worms in initially sterile (sintered-glass-filtered) pond water, starting with four brief washes and continuing with two longer washes (24 hr. and 48 hr. respectively), we selected 25 worms and transferred them to a solution of antibiotics similar to that used by Miller and Johnson (exceptions: penicillin *G*, 1,000 U./ml.; streptomycin sulphate, 100 γ/ml.; filipin, omitted). Worms left for 2 days thus and then washed six times in sterile pond water were found not to have been axenized. But one out of three worms put through another wash of 2 days (totalling 5 days of washing) and then 7 days in the foregoing antibiotic mixture was afterwards found to be free of bacteria.

With a number of animal organisms, both protistan and metazoan, monoxenic culture has been a preliminary to successful axenic culture (that is, to growing in the absence of living organisms of any other species)[3]. Our aim with *E. fragmentosus*, as it was with rhabditid nematodes[4] and is at present with rotifers and gastrotrichs[5], is to put it into axenic culture and thus make it available for nutritional and metabolic studies. The organism is of particular interest because of its extensive regenerative powers (in sharp contrast to the inability to regenerate exhibited by the aschelminths—nematodes, rotifers, gastrotrichs).

To the best of our knowledge this is the first time an annelid has been put into monoxenic culture. The axenic cultivation of an annelid has yet to be achieved. It is our next goal with *E. fragmentosus*.

We wish to thank the National Science Foundation for partial support of this work (through Grant *G*-6018).

Life-like Preservation of Cytoplasmic Detail in Plant Cells

BIOCHEMICAL and physiological data from plant material are reported frequently as the amount or activity of matter per cell, yet remarkably few such studies are made directly on the cells. Thus, for example, in a large number of publications on the chemistry and physiology of cell differentiation, very few have included any cytochemical investigations. That this is a general phenomenon is due, very largely, to the fact that no method exists by which plant cells may be investigated both for structure and for chemical activity, without the introduction of gross artefacts[1]. Animal cytology has advanced more rapidly because of the technique which involves freezing and drying the tissues, which are then embedded directly in paraffin wax and sectioned[2]. The wax is removed with xylol and the cells are fixed in absolute alcohol. This procedure has failed when applied to plant cells; moreover, the use of fat solvents is to be avoided at any stage.

The present communication describes a new procedure for producing sections of plant tissues in which the cytological detail is retained, apparently as in life. Thus, for example, sections of meristematic cells from roots have been obtained which resemble the living cells isolated from similar roots, as described previously[3]. Moreover, this method can be used in as routine a manner as is the usual technique which involves embedding the tissue in paraffin wax.

The tissues are treated first for about 2 hr. with a 5 per cent (w/v) aqueous solution of polyvinyl alcohol (Bush, Beach and Guest, *PVA*, type *MO*5/140). They are then frozen at between − 40° and − 70° C. in small glass specimen tubes (2 in. × 1 in.); freezing should be complete, as judged by eye, within 5–10 sec. This can be effected most simply by cooling the tubes first, for some hours or overnight, in solid carbon dioxide. The frozen material can be stored at − 40° C. or at lower temperatures, or it can be sectioned directly at between − 20° to − 25° C. by means of a refrigerated freezing microtome[4]. The sections are dried under vacuum in a desiccator containing phosphorus pentoxide and maintained at below − 20° C.

The function of the polyvinyl alcohol is to stabilize delicate cellular structures, for which purpose it has been used in other work[5]; it may be dispensed with where such labile organelles do not occur. Very low temperatures are to be avoided as they seem to damage plant cells, while gross ice crystal artefacts are apparent if the temperature of freezing is nearer 0° C., or if freezing is slow for any other reason, for example, if the tissue does not make immediate contact with the chilled wall of the tube.

It will be noted that this procedure differs markedly from the conventional freezing and drying method for animal tissues in that it depends on relatively slow freezing, as compared with the rapid quenching at the temperature of liquid nitrogen used in the latter. The reasons for this difference are twofold; first, because the results indicate that plant cells require such treatment, and secondly, because whenever tissue is to be maintained alive in a frozen condition it is cooled slowly[6]. This latter reason has been strengthened further by work such as that of Asahina[7], who observed, and photographed, living plant cells at temperatures below 0° C. He, and many other workers[8], suggest that when the cells are cooled at an optimal rate, the extracellular water freezes first and desiccates the intracellular protoplasm; for this to happen, the cell membrane must remain intact as it acts as a barrier to the extracellular ice-crystals. The complete lack of intracellular ice-crystal artefacts makes it reasonable to suppose that at these temperatures the protoplasm either never freezes, remaining in a supercooled condition, or that, possibly at very low temperatures, it may freeze but has too low a concentration of water to cause much damage. It is probable, however, that under the conditions used in the present technique, the former condition occurs; this seems likely in view of the gross distortion which can be produced by having the knife too blunt or set at the wrong angle.

The method has been used satisfactorily on root tips of *Allium cepa*, on roots and stems of *Vicia faba*, on leaves of *Ranunculus repens*, *Narcissus poeticus*, *Sorghum* and on leaves of the ferns *Ceterach officinarum* and *Dryopteris filix mas*. In the roots there was no sign of deformation so that cell lineages could be decided easily, the cytogenerative centre being very obvious (Fig. 1). Most striking, however, was the excellent preservation of the very delicate cytoplasmic granules in the active meristematic cells, which are almost never retained by other procedures[1] (Fig. 2). Normal Feulgen-stained preparations can be produced from such sections although the granules are acid-labile. In the leaves, too, no deformation was seen, as demonstrated by the good preservation of guard cells and of the cells lining the air space below. Weak birefringence has been observed in the chloroplasts and strong birefringence in all cell walls, not only in those of secondarily thickened elements. In the cells of leaves, too, more cytoplasmic detail was preserved by this procedure than by any other used previously by us[8]. Some leaves were grown in the presence of carbon dioxide labelled with carbon-14, and water-soluble substances were demonstrated in autoradiographs prepared by the apposition technique (Gahan, P. B., unpublished work) used on such frozen, sectioned and dried sections. This technique has also made possible a study of the effect of drought on plant tissues since the dried cells were chilled, sectioned and examined dry, without water or other fluids having been used at any stage of the preparation.

It seems likely, therefore, that this may be the method of choice for future studies in plant cytology and cytochemistry. It appears to give plant cytologists the equivalent of the freezing and drying technique, which has assisted so greatly the study of animal cells, yet it is simple to perform and considerably quicker than are the usual methods.

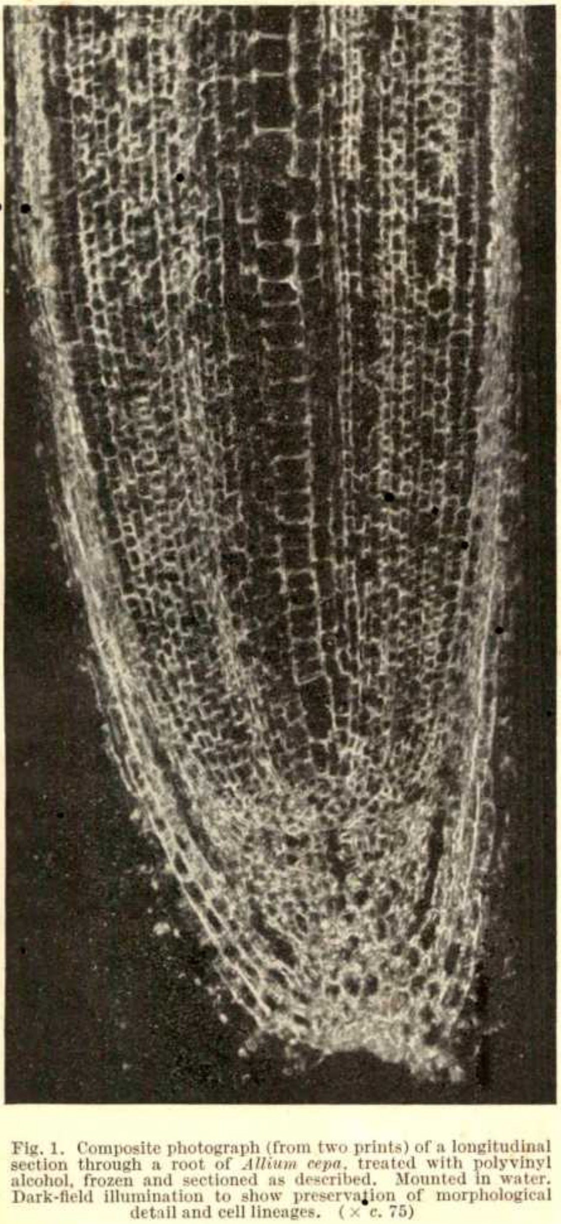

Fig. 1. Composite photograph (from two prints) of a longitudinal section through a root of *Allium cepa*, treated with polyvinyl alcohol, frozen and sectioned as described. Mounted in water. Dark-field illumination to show preservation of morphological detail and cell lineages. (× c. 75)

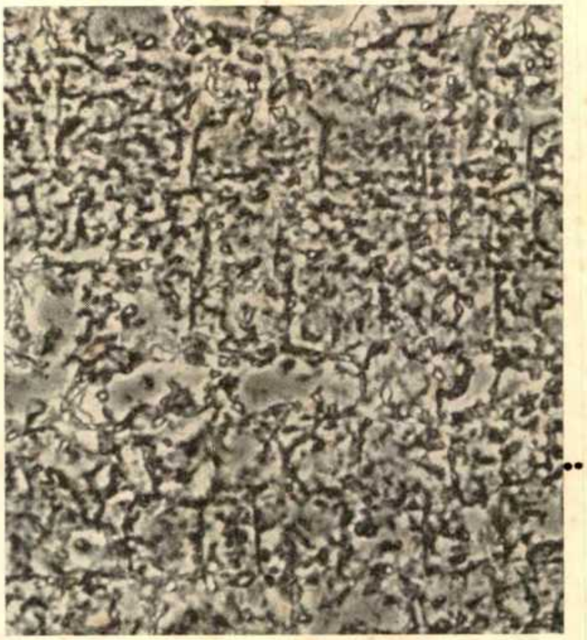

Fig. 2. As Fig. 1. Photographed with phase contrast illumination to show cytoplasmic granular and mitochondrial structures. (× 600)

A fuller account of the technique, and of results obtained by its use, will be published elsewhere[9].

Sulphydryl Content of the Embryos of the Australian Cattle Tick

Thompson and Johnston[1] reported that the total sulphydryl content of embryos of an arsenic-resistant strain of the South African blue tick (*Boophilus decoloratus*) was approximately twice that of an arsenic-susceptible strain. Harington[2] afterwards examined larvæ of these strains and reported that the cystine–cysteine, glutathione and total free sulphydryl values were significantly higher in the arsenic-resistant strain. To establish whether the same relation as reported by Thompson and Johnston

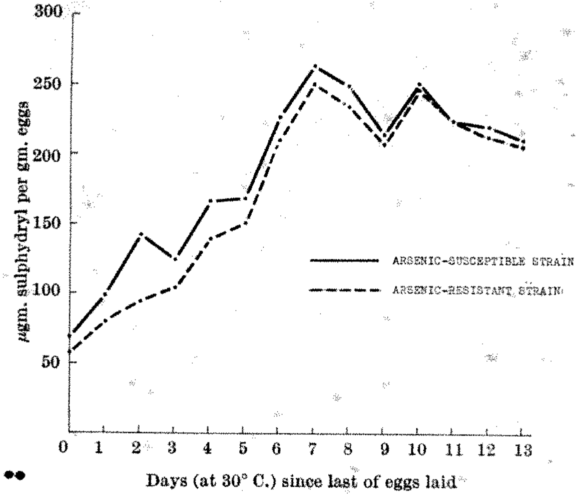

Fig. 1. Sulphydryl content of eggs of arsenic-susceptible and arsenic-resistant strains of *Boophilus microplus* throughout development

held in *Boophilus microplus*, investigations were carried out with a strain from northern New South Wales, larvæ of which exhibited a 10·7 fold (9·3–14·0; $P < 0{\cdot}001$) degree of resistance to arsenic in comparison with those of the susceptible Yeerongpilly reference strain. Adults of both strains were maintained at 30° C. and the ticks removed from the containers four days after oviposition had commenced. Daily thereafter throughout incubation four samples of eggs were taken and their total sulphydryl content determined by a nitroprusside method[3], using as a standard a solution of glutathione freshly prepared each day.

The sulphydryl content of samples of both strains up to the day before hatching commenced are shown in Fig. 1. During the first nine days of sampling the sulphydryl content of the arsenic-resistant strain was significantly lower than that of the susceptible strain (day 0, $P < 0{\cdot}05$; days 1–8, $P < 0{\cdot}001$), and at no time was the sulphydryl content of the arsenic-resistant strain significantly higher than that of the susceptible strain.

It is clear that the stage of development must be taken into account in comparing the sulphydryl content of embryos of different strains of *Boophilus microplus*, and therefore it is desirable to use eggs laid over the shortest possible period for such analyses. In this case the four-day period of oviposition which was allowed, to obtain sufficient eggs for analyses, was effectively three days, as very few eggs are laid on the first day of oviposition[4]. Owing to the nature of the curve, it is now realized that a more precise result would be obtained if eggs laid on one day only were used. However, the technique employed does not invalidate the results, because both strains were treated similarly.

Thompson and Johnston do not give details of the age-range or conditions of incubation of the embryos of *B. decoloratus* which they analysed, so that it is not possible to determine the extent to which differences in mean age could have influenced the relative amounts of sulphydryl compounds in their two strains. *B. decoloratus* may differ genuinely from *B. microplus* in this regard, but even making some allowance for errors which may arise from the age-spread of our cultures, it does not seem possible to correlate arsenic-resistance in *Boophilus microplus* with greater relative abundance in the resistant strain of compounds containing sulphydryl groups.

Thanks are due to Mr. B. F. Stone for determining the degree of arsenic-resistance of the strains of ticks and to Mr. K. P. Haydock for statistical treatments.

GENETICS

Genetic Instability and Outcrossing in the Groundnut Variety Mani Pintar

IN the course of groundnut variety selection work carried on in Northern Rhodesia since 1954, a number of unusual groundnut varieties have been obtained from various sources. The most unusual and interesting of these has been the variety Mani Pintar, obtained from the Queensland Department of Agriculture and Stock, Australia, in the early part of 1955. This variety has yielded consistently well in trials and appears to be well adapted to local conditions. It suffers, however, from the serious disadvantage of having a variegated red and white testa; in all other respects the variety is eminently satisfactory. Mani Pintar is an alternately branched spreading bunch variety which matures locally in 140–150 days, it has dark green foliage and is fairly resistant to the *Cercospora* leafspots, the seeds remain dormant for some time after maturity, the kernel oil content is fairly high (about 50 per cent) and is higher than most locally grown varieties; in addition, the yields of kernels and hay are consistently good. The combination of bunch habit and variegated red and white testa found in this variety is rather unusual. In *Arachis nambiquarae* Hoehne, a form with a similarly variegated testa, the habit is prostrate.

In their review of relevant literature, Gregory, Smith and Yarbrough[1] note the apparent instability of pure lines of groundnuts in the absence of selection pressures and summarize present genetical knowledge of the inheritance of colour and other kernel characters. Instability of pure lines may arise from two causes—chromosomal instability and natural outcrossing. A study of Mani Pintar showed that this variety exhibits a degree of instability; it was therefore decided to exploit this so far as possible in an attempt to produce from it a type which retained its many good qualities, but which was more acceptable commercially. In 1956 single plant selections were made some of which differed from Mani Pintar in having a self-coloured red testa. One strain which showed promise was selected for trial against the parental strain and not only was it little if any inferior to it in yielding capacity but also it bred substantially true. Occasionally reversions to the parental type were noted; but these formed only an infinitesimal fraction of the bulk of this new strain. It is possible that the change from variegated to non-variegated is reversible and results from rearrangement of chromosomal material and not from allelic differences, that it is in fact a position effect. From the practical point of view, by maintaining the selection pressure in favour of self-coloured testas, it should be possible to maintain this strain indefinitely. Varieties with red testas are well known in commerce, for example, Valencia, and this strain should not therefore be under any disadvantage in this respect.

It was noted in the course of seed selection in Mani Pintar stocks that a number of brown kernels were being discarded. On closer inspection some of these russet-brown kernels were found to be variegated. Variegation of brown kernels has not been reported by Gregory, Smith and Yarbrough[1] or by Bunting[2]; this character has re-appeared in subsequent generations. The remaining russet-brown non-variegated kernels were planted, and at harvest proved to be a mixture of material which showed definite affinities to Mani Pintar and other material which appeared to be present as a result of contamination.

It is now apparent that the brown-seeded material of Mani Pintar origin, both variegated and non-variegated, is of a hybrid nature. Segregation is occurring within single plant progenies for a great number of morphological characters. Variegated red and white kernels have appeared in pods of some progeny which are quite unlike those of the original Mani Pintar strain.

This work is continuing, and it is hoped to present elsewhere a more detailed account at a later date.

Interspecific Hybrids of *Lycopersicum*

In a recent issue of *Nature*, H. Nirk[1] described the achievement of fertile interspecific tomato hybrids by the reciprocal grafting of parent plants prior to hybridization. The technique has an older history than is suggested by Nirk's communication. It was used on a large scale more than thirty-five years ago by the Russian plant breeder I. V. Michurin, who termed it "vegetative approximation".

In a report[2] published in 1925 Michurin commended his own innovation in the following terms:

"My original method has been elaborated on the basis of the considerable changes that the properties of a small part of a young plant (a cutting) undergo when grafted on to the crown of a different variety. These changes take place under the action that the entire root and leaf system of the latter exerts upon a very small part of a young plant that is as yet rather unstable in respect to various changes . . .

"I use this vegetative change as an auxiliary means of approximating two different plant species so as to obtain a sexual hybrid by crossing them in the future.

"This is the secret of my success in obtaining interspecific plant hybrids, such as crosses between the apricot and the plum, sweet and sour cherry, *Pyrus salicifolia* and the local cultivated pear varieties; between the various species of walnut, the various species of grapes, the various species of quince; between the pear and the mountain ash; between distant species of apple; between species of currant and other small-fruit shrubs; between pumpkins and muskmelon, musk and watermelon; between the various species of lilies; between Physalis and tomatoes, etc."

Michurin's published descriptions do not in general lend themselves to exact scientific evaluation, so that it is not easy to say how many of his successful crosses were in reality facilitated by the 'approximation' procedure. On the other hand, at least one claim for the method made by members of his school[3] has been independently confirmed. Hall[4], working in Sweden, was able to increase the yield of wheat-rye hybrids from 2–3 per cent to 14 per cent, by grafting the embryo of the future maternal parent (wheat) on to rye endosperm.

It is to be hoped that the new results reported by Nirk will once more direct the attention of geneticists and embryologists to a challenging, and still unexplained, phenomenon.

Dr. Michie is of course correct in his statement regarding the claims of Michurin *et al.* in respect of this approach to interspecific hybridization. However, irrespective of whether the results of the present investigation furnish corroborative evidence of Michurin's claims, their immediate significance lies in their application in the field of practical plant breeding, particularly in relation to the hybridization of *Lycopersicum* species.

PSYCHOLOGY and PSYCHIATRY

Cross-Modal Transfer of Training in Monkeys

In a previous communication[1] the question was raised whether monkeys that have been trained to discriminate at a high level of confidence between two dissimilar solid forms by vision (in the light) will maintain their accuracy of discrimination when objectively the same cues are later made available for discrimination only by palpation (in the dark). The absence of cross-modal transfer between visual and tactile shape discriminations was reported for four unoperated monkeys. Support of this finding was forthcoming from the study of seven additional animals with brain lesions[2].

It was decided to extend this investigation to another sensory modality, and to look for cross-modal transfer between pairs of visual and auditory rhythms.

Table 1. SEQUENCE OF TRAINING FOR ANIMALS *C*1–*C*4, *F*1–*F*4 AND *T*1, *T*3, *T*4

<table>
<tr><th colspan="2">Group I animals</th><th>Group II animals</th></tr>
<tr><th>C1, F1, T1</th><th>C2, F2</th><th>C3, C4, F3, F4, T3, T4</th></tr>
<tr><td colspan="3">Visual shape discrimination
Interrupted tone versus click</td></tr>
<tr><td colspan="2">Low versus high visual frequency</td><td rowspan="3">Visual rhythm discrimin. (failed)
Visual rhythm versus dark</td></tr>
<tr><td>Auditory rhythm discrimin. (failed)</td><td>14 days rest</td></tr>
<tr><td colspan="2">Low versus high visual frequency (retention)</td></tr>
<tr><td colspan="3">Low versus high auditory frequency (1,000 trials)</td></tr>
</table>

However, not one of nine animals was able (under our conditions) to discriminate accurately between two simple visual or auditory rhythms within 3,000 trials of training. It was therefore asked: Will monkeys that have been trained to discriminate between two rates of interruption of a light maintain their accuracy of discrimination when a sound is interrupted at the same two rates ?

Eleven naïve rhesus monkeys (weight-range 3·5–4·7 lb.) were divided at random into two groups of five and six animals. No animal received a brain lesion. Their training histories (equated in the sense of one auditory and two visual tests learnt by each group) are shown in Table 1.

Standard apparatus (Wisconsin General Testing Apparatus) and the pull-in technique were used. By pulling one of two strings the animal could draw towards itself along sloping rails the left or right box, which on release returned by gravity to its starting position. Each box contained a light source, a loudspeaker and a food container. The onset of the light or sound was switched by tension on a string, although the frequency and modality of the cue had been silently predetermined on a control panel. Forty trials were given each day (non-correction) with right/left positions of the positive cues determined by the Gellerman schedule.

The luminance of the light was 229 ft. lamberts against a ground of 0·04 ft. lamberts. The sound was a 370 c.p.s. tone with a small component at 1,850 c.p.s. Its intensity was judged to be about 60 decibels above the hearing threshold, against a constant background noise of about 20 decibels. For the positive cues, the light or sound was interrupted at a rate of 4 c.p.s., for the negative cues, at 16 c.p.s. The on/off ratio of the positive cues was 0·44 in both modalities. The energy content of the high-frequency light was greater than that of the low-frequency light in the ratio of 1·7 : 1, owing in part to the thermal delay of the filaments ; of the high-frequency sound relative to the low-frequency sound in the ratio of 1·3 : 1, owing to an increase in the on/off ratio with frequency.

The animals of Group I required an average of 1,178 trials to learn the visual frequency discrimination (range 500–2,030 trials). The mean of their scores during retention training in the visual modality was 122 trials (range 0–380 trials). On the auditory form of the same frequency discrimination the mean error score in 1,000 trials is 352 for the five animals of Group I (range 265–414 errors) as compared with a mean of 347 errors for the six animals of Group II (range 295–408). The difference between the error scores of Group I and Group II animals does not approach significance (*P* = 0·465, one-tailed Mann–Whitney test). There was one animal in Group I and there were three in Group II that made 20 or less errors in the last 100 trials of training on the auditory frequency discrimination. These results provide no evidence of transfer between visual and auditory frequency discriminations in the monkey.

In a review of the literature[1] unequivocal evidence of positive cross-modal transfer in animals was found only in respect of the avoidance situation, with use of a single warning cue. Moreover, certain findings in man[3] indicate that cross-modal matching of lengths or nonsense shapes can be considerably more difficult than intra-modal comparisons. The authors of a recent report[4] state, " . . . we feel no doubt that inter-sensory rate matching between the eye and the ear (in man) is much poorer than intra-sensory matching for either of these sensory processes". Nevertheless under different conditions, cross-modal matching can be accurately accomplished by man[5]. We suggest that language may serve as a cross-modal bridge under these latter conditions[5], but perhaps not when small differences in lengths or rates have to be observed[3,4], nor in the experiment described in this report.

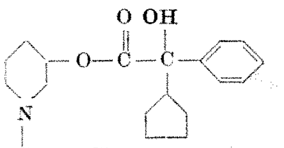
Blocking Effect of Tetrahydroaminacrin on a New Psychotomimetic Agent

TETRAHYDROAMINACRIN, a cholinesterase inhibitor, has been found to be an effective antidote to induced 'model psychosis' as well as the central and peripheral effects of an acetylcholine inhibitor, *JB* 329, in eight cases.



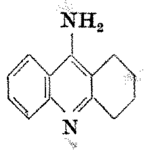
(I)

N-Ethyl-3-piperidyl cyclopentyl phenyl glycolate hydrochloride

The compound designated *JB* 329 (I) is a member of a series of 3,4-substituted piperidyl benzylates which have been recently demonstrated to possess psychotomimetic properties[1,2]. This compound has clinical effects that simulate some aspects of psychosis more closely than lysergic acid diethylamide or mescaline and is therefore of considerable interest.

The anticholinergic effect of *JB* 329 on guinea pig ileum is comparable to and may exceed atropine. It also is a weak antihistaminic but has no anti-serotonin activity (Research Division of Chemistry and Pharmacology, Lakeside Laboratories). Substitution of H for OH in the benzylic acid nearly abolishes psychotomimetic properties and consequently greatly reduces anticholinergic potency, whereas substitution of a quaternary nitrogen in the piperidyl ring also abolishes psychotomimetic properties, but has little effect on anticholinergic properties.

Tetrahydroaminacrin, 1,2,3,4-tetrahydro-5-amino-acridine (II) was synthesized by Albert *et al.* in 1945 [3].



(II)

1,2,3,4-Tetrahydro-5-aminoacridine

Rubbo and others[4,5] have shown that 1,2,3,4-tetrahydro-5-aminoacridine has no bacteriostatic properties in contradistinction to other related acridines. Later this compound was shown to possess a significant antagonistic effect to morphine depression in dogs[6], producing good arousal with the animal appearing normal and alert. This stimulant effect, the production of alertness with increased mental clarity, has also been observed clinically when 1,2,3,4-tetrahydro-5-aminoacridine has been added to the high morphine dosages frequently employed in patients with severe pain from terminal carcinoma (Shaw, F. H., personal communication).

1,2,3,4-Tetrahydro-5-aminoacridine has marked anticholinesterase activity, is an effective decurarizing agent[7], displays eserine-like activity on the intestine, and atropine-like properties on the heart.

Therefore it seemed that 1,2,3,4-tetrahydro-5-aminoacridine would warrant a trial as an antidote to the peripheral and central effects induced by *JB* 329. Preliminary screening was carried out in animals and 1,2,3,4-tetrahydro-5-aminoacridine was found to counteract the increased activity produced in mice by *JB* 329 as measured in an activity cage.

Clinical trials were then undertaken, and 1,2,3,4-tetrahydro-5-aminoacridine, given intravenously, was a complete and effective antidote for both the central and peripheral effects of *JB* 329 in eight subjects. To date we have studied the effects of *JB* 329, given both orally and intramuscularly, in a large number of cases. In the present work four chronic alcoholics, one sociopath and three schizophrenics were given 10–20 mgm. of *JB* 329 intramuscularly. All subjects were able to speak adequately. Autonomic symptoms such as mydriasis, tachycardia, dryness of the mouth and muscle weakness were seen in all the subjects. The central effects produced in these subjects and in many others studied were essentially the same as those already reported by others. These began about 20 min. after administration of the drug and consisted of confusion, difficulty in speech and concentration, disorientation and hallucinations. Hallucinations were visual, olfactory, tactile and auditory, lasted up to 24 hr. and reproduced earlier real or hallucinated experiences. They were accompanied by gross distortion of visual perception, and by hallucinating objects and people. A number of subjects exhibited paranoid ideation and ideas of grandeur. Some showed complete loss of contact with the environment and reacted to their hallucinations. In some cases stupor and mussitant delirium were produced.

One illustrative case will be presented. This patient, *M*, an alcoholic with good verbal level and little deterioration, was given 10 mgm. *JB* 329 intramuscularly. He became for a time confused and drank imaginary glasses of alcohol, refilling them from non-existent bottles. His speech also became progressively more incoherent until in about 1½ hr. he became stuporose, with eyes staring fixedly ahead, and unable to articulate any word or sound, and with his limbs markedly hypotonic. At this point 30 mgm. 1,2,3,4-tetrahydro-5-aminoacridine were administered intravenously over 5 min. Two min. after commencement of the injection he spoke and responded rationally, was alert and in complete contact. Muscle tone was restored to normal and he could walk without assistance. He did not relapse into stupor, and conversation was at all times clear and lucid and showed no evidence of a return to confusion, disorientation or the production of psychotic material of a delusional or hallucinatory type. This type of response is typical for alcoholics given *JB* 329.

Subjects belonging to different diagnostic categories respond to *JB* 329 with distinct and different pictures. These will be reported in detail elsewhere (Gershon, S., and Olariu, J., unpublished work).

In all eight cases, the intravenous injection of between 30 and 60 mgm. of 1,2,3,4-tetrahydro-5-aminoacridine was a complete antidote to the *JB* 329-induced state, whatever the predominant clinical picture. Furthermore, the 1,2,3,4-tetrahydro-5-aminoacridine reversed the blood pressure and heart-rate changes induced by *JB* 329, whether initially an elevation or a depression of these functions occurred.

These observations demonstrate that 1,2,3,4-tetrahydro-5-aminoacridine, a cholinesterase inhibitor, is a successful and complete antidote to the 'model psychosis' induced by *JB* 329, in both non-psychotic and psychotic subjects. Although these two compounds affect cholinesterase and acetylcholine *in vitro*, this may not necessarily be their mechanism of action in producing the changes reported here. However, it is felt that this is a promising area for further investigation.

STATISTICS

The Meaning of Binomial Distribution

Two generalizations of the simple binomial distribution are common in statistical text-books, one due to W. Lexis and the other to S. D. Poisson. Lexis considered the case in which the probability of an event occurring, p, is constant in the N trials of one experiment, but varies among several such experiments. He showed that the mean and variance of the resulting binomial distribution are $N\bar{p}$ and $N\bar{p}\bar{q} + N(N-1)V(p)$, where $\bar{p} = 1-\bar{q}$ is the mean, and $V(p)$ the variance, of p between experiments. The variance thus exceeds that of the simple binomial distribution with the same mean. Poisson considered the case in which p takes the value p_i at the ith trial in each experiment, and showed that the mean and variance of the resulting distribution are $N\bar{p}$ and $N\bar{p}\bar{q} - NV'(p)$, where $V'(p)$ is the variance of p within experiments.

In order to specify the exact form of the modified binomial distribution, it is necessary to postulate a distribution for p, in the first case, and the values p_i in the second. A convenient distribution for p is the β-distribution, and the resulting Lexian binomial has been described and used by Edwards[1] in connexion with work on the human sex ratio. The Poisson binomial is not commonly used, although to do so would be a simple, if tedious, matter. Parkes[2] gives some data on the sex ratio in pigs which exhibit unexpectedly small variances, and if he had known of this distribution he need not have observed that his was "a finding very hard to interpret".

David[3] describes Lexian and Poissonian variation adequately, including the case in which both types occur simultaneously. But she perpetrates a common fallacy when she concludes that if the observed variance of a binomial distribution does not differ significantly from $N\bar{p}\bar{q}$ then "the probability may be assumed to be constant throughout the observations". For the two types of variation may be masking each other, and the only valid inference is that there is no evidence for variations in the probability.

I have recently found a third generalization of the simple binomial distribution useful. Suppose that the probability is p at each trial, but that the result of a trial is causally correlated to the result of the previous one, with correlation coefficient r. Then, formulating the problem like a Markov process, the matrix of transition probabilities from one trial to the next is:

$$\begin{pmatrix} p + rq & q - rq \\ p - rp & q + rp \end{pmatrix}$$

and the generating function of the 'Markov binomial' distribution is:

$$G(s) = (ps\ q) \begin{pmatrix} (p + rq)s & q - rq \\ (p - rp)s & q + rp \end{pmatrix}^{N-1} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

where s is a dummy variable.

The matrix of transition probabilities has the interesting property:

$$\begin{pmatrix} p + rq & q - rq \\ p - rp & q + rp \end{pmatrix}^{N} = \begin{pmatrix} p + r^N q & q - r^N q \\ p - r^N p & q + r^N p \end{pmatrix}$$

Thus the correlation coefficient between trials separated by $N-1$ other trials is r^N. The coefficient is, in fact, the determinant of the matrix.

The mean of the distribution is clearly Np, and the variance can be found from the formula for the variance of the sum of N correlated variables:

$$\sigma^2 = Npq + 2(N-1)rpq + 2(N-2)r^2pq + 2(N-3)r^3pq \ldots + 2r^{N-1}pq$$

$$= Npq + 2pq \cdot \frac{r}{(1-r)^2} (N(1-r) - 1 + r^N)$$

This variance exceeds Npq if the correlation is positive, but is less than Npq if the correlation is negative.

In practice it is impossible to separate out the three effects here described when the data are solely in the form of binomial distributions; but if the data are available broken down into series, an analysis may be made:

It can be shown that the correlation coefficient between successive trials is equal to:

$$r + (1-r) \frac{V(p)}{pq}$$

where r is the correlation coefficient between successive trials within experiments and $V(p)$ is the variance of p between experiments. Small variations in p between trials are second-order effects in the expression and may be neglected. Thus the correlation coefficient between trials separated by $(N-1)$ other trials is:

$$r^N + (1-r^N) \frac{V(p)}{pq}$$

and this formula enables V and r to be estimated. Variation in p between trials may, of course, be estimated directly.

We are thus equipped to analyse binomial data on the fairly comprehensive hypothesis that the probability of an event occurring at the ith trial in the jth experiment is $p_i + p_j$, where the p_i's are small and $\sum_i p_i = 0$, there being an additional real correlation, with coefficient r, between the results of successive trials in an experiment. Further generalization may, of course, be made, at the risk of some complexity, but it is doubtful whether any data exist that warrant it.

In conclusion, it must again be emphasized that no useful inferences can be made from the fact that data fit the simple binomial distribution satisfactorily; for, on one hand, variability of p between experiments, and a positive correlation between successive trials, increase the variance, and on the other, variability of p between trials, and a negative correlation, reduce it.

A. W. F. EDWARDS

Department of Genetics,
University of Cambridge.

Feb. 12.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Assistant, for work on the structure of crystalline proteins using X-rays and electronic computers—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (June 29).

Assistant Lecturer (with a degree in botany with some zoology) in Biology—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Demonstrator in the Department of Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Laboratory Technician (with experience of chemical or biochemical analysis) in the Department of Veterinary Hygiene and Preventive Medicine—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, quoting Ref. No. LT/VH/5/60 (June 30).

Lecturer in Applied Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (July 3).

Assistant Lecturer in Pure Mathematics—The Registrar, The University, Sheffield (July 9).

British Coke Research Fellow in the Department of Chemistry, for research on the carbonization of high polymers—The Registrar, The University, Hull (July 9).

Lecturer (Grade I) in Pure Mathematics—The Registrar, The University, Leicester (July 9).

Shell Students (graduates in chemistry or engineering) in Chemical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (July 4).

Assistant Lecturer or Lecturer in the Department of Zoology—The Registrar, The University, Liverpool, quoting Ref. No. CV/T (July 9).

W. J. Rees Research Fellow (with some research experience) in the Department of Refractories Technology in the Faculty of Metallurgy, to advance knowledge in the field of refractory materials—The Registrar, The University, Sheffield (July 9).

Research Assistant (with a good honours degree in botany or agricultural botany and an interest in experimental ecology and/or genetics) in Agricultural Botany, for investigations on the mineral nutrition of natural populations of agriculturally important grass species—The Registrar, University College of North Wales, Bangor, North Wales (July 15).

Assistant (preferably with an interest in systematics of the fungi) in Botany—The Secretary of University Court, The University, Glasgow (July 16).

Fellow (chemist or biochemist, with the Ph.D. degree or about to obtain it) in the Chemistry Department of the Faculty of Science, for the study of nucleotides in relation to the bacterial cell wall—The Registrar, The University, Manchester 13 (July 16).

Lecturer in Electronic Computing—The Registrar, The University, Leeds 2 (July 16).

Student (with good honours in a first degree in physics) in the Department of Physics, for research on the thermionic and related aspects of the direct conversion of thermal to electrical energy—The Professor of Physics, The University, Southampton (July 16).

Fellow or Senior Fellow in the Department of Physical Biochemistry, John Curtin School of Medical Research, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 18).

Senior Lecturers and Lecturers in Chemistry, Mathematics, Physics, Zoology and Engineering at Monash University, Clayton, Victoria, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (July 18).

Temporary Assistant Lecturer or Temporary Lecturer (preferably with interests in applied mathematics) in the Department of Mathematics—The Secretary, University College, Gower Street, London, W.C.1 (July 20).

Assistant Forest Entomologist (with a degree or diploma in science or an applied science with training and aptitude for forest entomological research) with the Forests Commission of Victoria, Australia, to undertake field investigations into the incidence and control of forest insect pests, under the Forest Entomologist and Research Officer—The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, London, W.C.2 (July 23).

Research Assistant in Theoretical Physics in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (July 23).

Lecturer (with a good honours degree and a special interest in mycology and plant pathology) in Botany at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 25).

Chair of Civil Engineering, and Chair of Electrical Engineering at the Royal Technical College of East Africa and proposed University College in Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 30).

Chair of Geography in Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, July 30).

Assistant Professor in the Department of Chemical Engineering—Head of the Department of Chemical Engineering, University of British Columbia, Vancouver, B.C., Canada (July 31).

Lecturer (preferably with experience in comparative physiology or experimental zoology) in Zoology at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 31).

Lecturer (with a degree in chemical engineering and experience in the practice of chemical engineering in industry and/or in teaching and research) in Chemical Engineering at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, July 31).

Senior Lecturer in Statistics; and a Lecturer in Pharmacy at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, July 31).

Director of the South Australian Institute of Technology, North Terrace, Adelaide, South Australia—The Agent-General for South Australia, South Australia House, 50 Strand, London, W.C.2 (August 20).

Lecturer in Archæology—The Secretary of University Court, The University, Glasgow (August 31).

Reader in Electric Traction at the Imperial College of Science and Technology, London, S.W.7—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 12).

Assistant Experimental Officers (2) (graduates), one for a trapping and marking programme and population and distribution studies (an unmarried man), and the other for the study of parasite ecology—The Assistant Director (Research), The Wildfowl Trust, Slimbridge, Glos.

Assistant, Grade B, in Mathematics—The Registrar, Bradford Institute of Technology, Bradford 7.

Assistant Lecturer in Physical Chemistry—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College of Science and Technology, London, S.W.7.

Assistant or Associate Professor (with Ph.D. or equivalent, plus demonstrated ability in pharmacology or related fields of physiology or biochemistry) in the Department of Pharmacology and Therapeutics—Dr. Mark Nickerson, University of Manitoba, Winnipeg, Canada.

Biochemist (Senior or Basic grade) to the Rochdale Group of Hospitals, to work under the Consultant Pathologist and to carry out biochemical work for the hospitals and clinics of the Group—The Group Secretary, Rochdale and District Hospital Management Committee, Central Offices, Birch Hill Hospital, Rochdale, Lancs.

Biochemist (non-medical) in the Department of Medicine, Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Head of the School of Librarianship, Manchester College of Science and Technology—The Secretary, The Library Association, Chaucer House, Malet Place, London, W.C.1.

Junior Physicist—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, marking envelope "Physicist".

Lecturer (with a good honours degree and preferably a higher degree) in Geology with emphasis on Petrology and Structural Geology—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Postdoctoral Fellow in the Department of Chemical Engineering, for research into flame spectroscopy or a related subject—Dr. A. G. Gaydon, F.R.S., Imperial College of Science and Technology, London, S.W.7.

Research Assistant (Physicist) (preferably with a knowledge of electronics and a degree in physics), for work with the X-ray scanning micro-analyser (electron probe) in the field of ore microscopy—Dr. A. P. Millman, Mining Geology Department, Royal School of Mines, Prince Consort Road, London, S.W.7.

Research Assistant (preferably with experience in cytology), to take part in a programme designed to study human chromosome abnormalities and associated disorders—The Secretary, Genetics Department, The University, Sheffield 10.

Research Fellow (with a Ph.D. degree or equivalent research experience) in the Chemistry Department, for work on the kinetics of gaseous oxidation reactions, in collaboration with Dr. R. R. Baldwin—The Professor of Chemistry, The University, Hull.

Research Student in Chemistry, for work on the chemistry of urease under the direction of Prof. W. Cocker—The Registrar, Trinity College, Dublin.

Senior Grade Technician (A.I.M.L.T. or B.Sc.) in the Biochemistry Department, for general routine work—The Secretary, Group 9 Pathological Laboratory, 6 Rickmansworth Road, Watford, Herts.

Senior Lecturer in Physics, and a Lecturer in Physics—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Senior Lecturer (well qualified, with industrial and/or research experience) in Organic Chemistry—The Registrar, Bradford Institute of Technology, Bradford 7.

Senior Technician II to take charge of the Biochemistry Department in the Group Laboratory—The Secretary, Forest Group H.M.C., Langthorne Road, London, E.11.

one gauge

gives independent readings

for chamber pressure

and temperature

COMPLETE RANGE OF

AUTOCLAVES

FOR THE MODERN LABORATORY

The single gauge on each of the new BTL 'Bara' autoclaves is angled for easy reading and shows chamber pressure and temperature independently. A B.T.L. regulator maintains set pressure to within ±½ lb. per sq. in., and a safety valve limits maximum pressure to 28 lbs. per sq. in. A perfect seal is obtained with easy hand-tightening of the heat-insulated lid handles. The autoclaves are convenient and safe in use and each autoclave is provided with a test certificate.

The range comprises vertical and horizontal models in various sizes. Heating of the standard models is normally by gas or electricity. Autoclaves conforming to B.S. 2646:1955 are also available. *Please write for full details.*

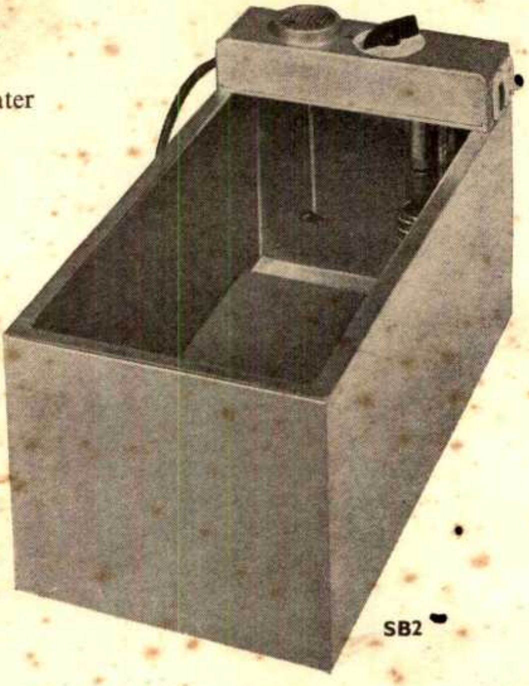
the standard laboratory bath

Stainless steel tank: Propeller stirring.
Dial marked in degrees Centigrade.
Available with pump for circulating water through other apparatus.
Wide range of test-tube racks, lids, cooling and constant level devices.
Unconditionally guaranteed for one year. Forty-eight hour repair service, and loan units available by return of post.

Standard Models
Range 10° to 100° C ±0·25° C

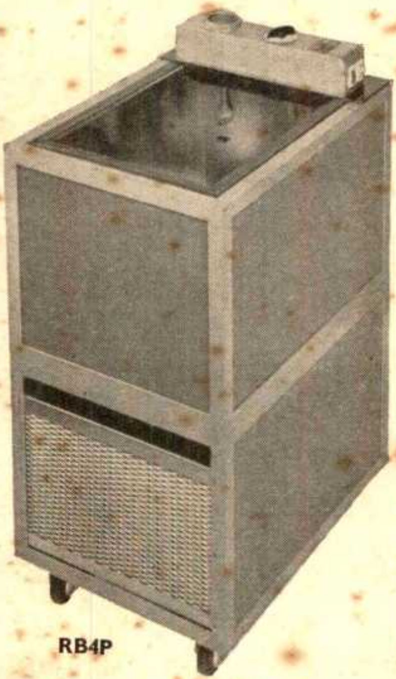
SB1 (9″×8″×6″) ...	**£27 5 0**
SB2 (15″×8″×6″) ...	**£28 10 0**
SB3 (21″×12″×11″)	**£32 0 0**
SB4 (15″×12″×9″)	**£31 0 0**

(working space in brackets)



SB2

low temperature bath



RB4P

Models RB4 and RB4P

Range −20° C. to +60° C. ±0.5° C.
This has all the features of our standard baths, but has a stainless steel heat extractor in the botton of the tank, driven by a refrigeration compressor in the lower section. If fitted with a pump (as illustrated) it can be used for circulating liquid at a controlled temperature through other apparatus.

Model RB4 (without pump)	**£97 10 0**
Model RB4P (with pump)	**£102 5 0**

(tank dimensions as SB4—see above)
